Articles to be annealed or tempered are heated to required temperature in a non-fusible bath heated by electric currents. The furnace used is of the type of magnesite or the like, closed, except as to the heating opening at the top, and the walls are protected against outward radiation of heat. The bath may be of silicates, carbides, carbonates, &c., a bath consisting of silicates of sodium chloride and 1 mol. of sodium-fluoride, being specified as suitable. The heating is effected by immersed electrodes, an alternating current being preferably used to avoid electrolysis, and the temperature is controlled by suitable means to ensure uniformity. — E. S.

Blast Furnace Gases; Method and Apparatus for Utilizing — available for Working Gas Motor Engines. H. Thwaite. Eng. Pat. 14,757, June 30, 1904. page 836.

UNITED STATES PATENTS.

Separator and Concentrator. R. T. Marshall, Merion Station, Pa. U.S. Pat. 793,945, July 4, 1905.

Series of connected pans is arranged on successively higher levels, each pan being of inverted angular shape with a sloping bottom, and provided at one side with a circular hopper discharging into its lower portion, and at the opposite side, with a spout projecting into the space between the next adjacent pan. There are transversely-arranged deflecting-lips arranged adjacent to the discharge of each of both the hoppers and the spouts, amalgamated with the pans, and the deflecting-lips are carried by one of the hopper lips, and the deflecting-lips are disposed on the lower side of the pan. There is a flat nozzle to each hopper lip, receiving a supply of water. — E. S.

Process of Extracting — from its Ores. G. Gin, Paris. U.S. Pat. 793,186, June 27, 1905.

Copper, Zinc, Cadmium, Silver, Nickel, Cobalt and Tungsten Hydroxides; Process of Obtaining — in the Wet Way, by Direct Extraction. D. Lance. Second Addition, dated Jan. 9, 1905, to Fr. Pat. 342,865, May 4, 1904. VII., page 845.

Zinc Furnaces heated by Gas. E. Derval, Fr. Pat. 351,055, Jan. 27, 1905.

The retorts, four groups of which are arranged in separate, but adjoining furnaces, are adapted to be heated together or separately, by gas from a producer, delivered through an aperture in the arch of each furnace, hot air being admitted at different elevations to the retorts, from the regenerating chambers, these being placed transversely to the furnaces, and beneath the main supporting wall of the latter. All parts of the furnaces are easily accessible for cleaning, and the regenerators are so arranged and connected as to permit of the flames being directed to the least heated parts as occasion requires. Cold air is admitted to the bases of the regenerators, and these are provided with boxes for collection and withdrawal of the soot. (See U.S. Pat. 762,578, of 1904; this J., 1904, 745.) — E. S.

Tantalum; Application of — in the Manufacture or Preparation of all Instruments, Tools, Surfaces, Points, Cutting Edges, &c., which are subject to Mechanical Wear. Siemens and Halske A.-G. Fr. Pat. 351,351, Feb. 8, 1905.

TANTALUM, or an alloy of the same with small proportions of silicon, boron, aluminium, titanium or tin, is applied to the purposes indicated in the title. Tantalum containing a small proportion of iron, or iron containing a small proportion of tantalum, is recommended for many purposes. Oxygen and hydrogen are included in the number of bodies that may be combined with tantalum. Among the applications claimed for certain of these alloys, are to the manufacture of watch springs, clock movements, pens, &c., and also to fixed objects, such as anvils. (See Fr. Pat. 337,607, of Dec. 12, 1903; and Eng. Pat. 21,766, of Oct. 10, 1904; this J., 1904, 494 and 1225 respectively.) — E. S.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(A).—ELECTRO-CHEMISTRY.

Electrolysis with alternating Currents. A. Brochet and G. Petit. *Z. Elektrochem.*, 1905, 11, 441—453.

THE authors have proved experimentally, that the action of alternating currents when used for electrolysis, varies with the chemical nature of the reaction. The action of the intermittent current at anode or cathode, may also differ from the action obtained by direct current under similar conditions, but if a Wehnelt interruptor or a mechanical circuit breaker be inserted in the direct current circuit, the actions obtained at the anode or cathode are alike in the two cases. Alterations in the current density of the alternating current, as a rule, have no effect upon the nature of the chemical reactions, but in special cases, such a change is to be noted. The general explanation of the chemical changes which occur during electrolysis with alternating currents, is that, for a very brief period, ions of opposite electrical charges are in close contact with one another, and if the speed of the chemical reaction be high, these ions unite again, and reform the original compound. In order to obtain other results from the electrolysis, it is therefore necessary to arrange, that one or other of these groups of ions shall have entered into combination before the ions of opposite electrical charge are liberated. The reaction speed and the alternating period have thus considerable influence upon the final results. The surface of the electrodes used with alternating currents has a tendency to become spongy, and thus the conditions at the end of an experiment may differ materially from those under which it was commenced. Very little practical use has yet been made of electrolysis with alternating currents, the formation of barium platino-cyanide being the chief application.—J. B. C. K.

(B).—ELECTRO-METALLURGY.

Alloys not containing Iron; Magnetic Qualities of ——. J. A. Fleming and R. A. Hadfield. Roy. Soc. Proc., 1905, 76, A, 271—283.

THE authors have determined the principal magnetic constants of two alloys similar to those prepared by Heusler (see Hadfield, this J., 1904, 985). Alloy No. 1 contained 22.42 per cent. of manganese, 60.49 per cent. of zinc and 11.65 per cent. of aluminium, together with 1.5 per cent. of carbon, 0.37 per cent. of silicon and 0.21 per cent. of iron. Alloy No. 2 contained approximately: manganese, 18; copper, 68; aluminium, 10; and lead, 4 per cent. The results obtained are arranged in a series of tables and curves. They show that the alloys possess magnetic properties identical with those of a feebly ferro-magnetic material. Alloy No. 1 has a maximum permeability of 28—30, a value not greatly inferior to those shown by cobalt or low grades of iron for small magnetic forces. Alloy No. 2 has a maximum permeability of 14. The two alloys have far greater hysteresis than pure iron, nickel or cobalt for corresponding cycles of magnetisation. They exhibit the phenomenon of magnetic retentivity; i.e., they are not merely magnetic, but can be permanently magnetised. The most important conclusion to be drawn from the results is that ferro-magnetism can no longer be regarded as a peculiar characteristic of certain chemical elements—iron, nickel and cobalt, but is due to certain magnetic groupings, since the two alloys examined respectively are fairly strong ferro-magnetic materials produced by admixture of metals possessing in themselves separately no such property.—A. S.

main specification (this J., 1905, 505), the voltage bath for the extraction of zinc with sodium sulphate is to be from 6 to 10 volts. The present claim that the voltage should be modified according to conditions of the process, such as concentration, nature and nature of the electrodes.—R. S. H.

II.—FATTY OILS, FATS, WAXES, AND SOAP.

Synthesis of — A. Grün. Ber., 1905, 38, 2284–2287.

author finds that a satisfactory method for the esterification of glycerol by sulphuric acid, and ester of the glycerol with solutions of fatty acids in concentrated sulphuric acid. The esterification of glycerol by sulphuric acid results in the quantitative formation of glycerol-disulphuric acid, $C_3H_5(OH)(OSO_3H)_2$, when excess of the acid is used, and consequently subsequent action of fatty acids, diglycerides are formed. The reaction between the glycerol ester and acids proceeds rapidly at a relatively low temperature; reversible, but good yields (70–80 per cent. of theoretical) of the glycerides are obtained. If rhodrin be used in place of glycerol, α , β -diglycerides are obtained instead of the $\alpha\alpha$ -compounds obtained when the latter is employed. By replacing the hydroxyl group in these diglycerides by an acyl group according to known methods, symmetrical or unsymmetrical triesters can be produced. The preparation of dipalmitin (m.pt. 70° C.), distearin (m.pt. 76° C.), diarachin (m.pt. 70° C.), β -acetodipalmitin (m.pt. of crystals, 49° C.; after previous fusion, 33° C.), dipalmito- α -chlorin (m.pt. 48°–50° C.), and α -acetodipalmitin (m.pt. 67° C.) is described.—A. S.

Use of Mineral Oil in Examining — by the *Mené Test*. F. Suzzi. Boll. Chim. Farm., 1905, 301–308. Chem. Centr., 1905, 2, 80–81.

examination of oils which give high values in the mené test, it is preferable to use olive oil as a diluent than mineral oil. Experiments with arachis, cotton-seed, curcas, olive, sesame and other oils in the apparatus (see this J., 1904, 668), showed that results obtained in the case of oils diluted with varying amounts of olive oil, always corresponded with those obtained with the undiluted oils, whereas in the presence of mineral oil, values were obtained which were higher than the true ones and which varied according to the quantity of mineral oil used. In cases where circumstances necessitate the use of mineral oil, the true Mené number, may be calculated by the aid of the formula; xv , where i is the increase of temperature observed, and v the volume of the mixture minus that of the mineral

oil and v the total volume of the mixture. Uniform results can never be obtained, however, in the case of drying oils such as linseed oil, by the use of mineral oil.—A. S.

XIV.—TANNING, LEATHER, GLUE, SIZE.

FRENCH PATENTS.

Tanning: Process of Electrical —. R. Berthou. Fr. Pat. 351,261, Feb. 4, 1905.

In the process of electrical tanning, it is claimed that the absorbent power of the hides is increased and rendered more uniform by subjecting them to the action of an electric current in the presence of a saline solution, as in the electrical process for drying green wood. The saline solution employed contains both plumping and astringent substances. An addition of manganese resinate is made to the tanning liquor to ensure the uniform absorption of the tannin. A suitable saline solution consists of: water, 10 hectolitres; crude barium chloride, 20 kilos.; hydrochloric acid, 30 litres; and crude sea salt, 200 kilos. The skins are immersed in this solution and subjected to the action of an alternating current of 25–30 volts. The tanning liquor may be composed of: water (at 30° C.), 10 hectolitres; oak bark, 100 kilos.; crude oil of turpentine, 2 litres; and manganese resinate, 1 kilo.; per 100 kilos. of hides.—A. S.

Viscine; Process for Purifying Crude — Obtained from Plants of the Ilex Class. W. Loebell, 1, Zschachwitz-on-the-Elbe. Eng. Pat. 26,383, Dec. 1904.

THE crude viscine, obtained from plants of the *Ilex* is kneaded with carbonate of lime, afterwards treated with a suitable dehydrating agent, and the mass extracted with benzene or a suitable oil. The solvent is distilled off, and the residual product is mixed, if desired, with a suitable oil, such as "fat mustard oil."—B.

FRENCH PATENT.

Sugar Syrup: Apparatus for Making and Filtering [Cold]. V. E. T. Noirot. Fr. Pat. 351,282, Jan. 28, 1905.

THE apparatus consists of a cylindrical vessel divided into two equal compartments by a circular perforated plate. On this plate is placed a membrane or skin and above latter a perforated arch-shaped metallic plate. The upper part of the cylinder is filled with sugar and in suitable proportions, whilst the lower part serves as receptacle for the filtered syrup. The lower and upper parts of the cylinder are connected by an external pipe to equalise the air pressure.—W. P. S.

XVII.—BREWING, WINES, SPIRITS, Etc.

Malt; Proteolytic Enzyme in Bavarian —. M. Krandauner. Z. ges. Brauw., 1905, 28, 449–4

BAVARIAN malt contains a powerful peptic enzyme, which acts most favourably at 50° C. A tryptic enzyme, which further breaks down the dissolved peptic products (albumins and albumoses) into amides, may also be present, in practical mashing operations it scarcely comes into play. In the Windisch mashing process, the activity of the peptase is considerably weakened owing to the high temperature (65° C.) employed and the rapidity of the process. By the adoption of this process, therefore, worts very poor in albumoses and other nitrogenous products are obtained. On the other hand, the mashing process yields worts containing the largest amounts of nitrogen and albumoses, owing to the low temperature employed, and to the fact that the peptase can exert its action practically until the wort is run off.—T. H.

Fermentation; Further Researches on Cell-free —. E. Buchner and W. Antoni. Chem.-Zeit., 1905, 29, Rep., 200; from Z. physiol. Chem., 1905, 44, 206

PRESSED yeast extract loses its fermentative power standing in the air for a few days, but no difference is exhibited between two portions of the same extract through which oxygen and hydrogen respectively have passed. Contrary to the observations of Bokorny, the author finds that, when highly and equally concentrated solutions of cane-sugar and dextrose in the yeast extract are prepared, the amount of fermentation is the same in both cases. Inversion will take place in a very concentrated solution of cane-sugar (20 grms.) in water (100 grms.), to which 0.2 c.c. of fresh pressed yeast extract is added.

When permanent yeast ("Dauerhefe") is pounded, its fermentative activity towards a solution of cane-sugar in either water or pressed yeast extract is temporarily injured.

aldehyde has but little action on sensitive enzymes in many cases may be used as an antiseptic, but fluoride has a strong injurious effect on the action of yeast. The addition of 0.05 per cent. of quinine chloride effects a slight increase on the fermentative power of permanent yeast prepared by means of acetone, but with permanent yeast gradually diminishes in amount as the quantity of ethyl alcohol added is increased. Acetone hinders fermentation to a greater extent than alcohol.—T. H. P.

Glucose Syrups; Fermentation Methods for the Vinification of —. von Raumer. XXIII., page 861.

ENGLISH PATENTS.

Manufacture of —. E. C. Schrottky, Calcutta. Eng. Pat. 28,619, Dec. 28, 1901.

The process deals with the addition to the wort or mash of a material prepared by the action of green or air-dried malt on raw or prepared grain mixed with spent yeast.—T. H. P.

and other Spirits; Maturing and Improving —. R. Hunt, Liverpool. Eng. Pat. 14,382, Dec. 25, 1904.

The process consists in adding sugar and hydrated silicate (moist pipeclay), either together or separately, to the raw spirit, blowing air through and so effecting the separation or decomposition of certain deleterious ingredients and then preferably distilling the spirit to get rid of the added saccharine matter, clay and dyes.—T. H. P.

and other Spirits; Treatment of —. R. Hunt, Liverpool. Eng. Pat. 14,827, July 1, 1904.

The fusel oil separated from the spirit in the usual manner is mixed, at a temperature of 70° F., with from 5 to 10 per cent. of its weight of sugar dissolved in a little water. From 5 to 10 per cent. of pipeclay mixed to form a slurry with water, is also added. A current of air is blown through the mixture for about one hour and the latter is then distilled. The product is added to the original spirit in the proportion of one part to 600 or 1000 parts.—W. P. S.

FRENCH PATENT.

ing Apparatus. E. Guillaume. First Addition, dated Jan. 25, 1905, to Fr. Pat. 288,270, April 27, 1899.

The improvements claimed relate to the process and apparatus described in the original patent, particularly to the position of the battery of diffusers and its various parts. The fermentation is carried out in a series of small vessels instead of a single one. Means are provided for cooling the juice and recovering the heat lost in the "vinasse." The method of aerating the juice by fermentation, by passing it over shallow inclined plates is also claimed.—W. P. S.

(A).—FOODS.

; Influence of some Constituents of "Whole-Meal" Flour on the Extraction of —. Lindet and Ammann. (Abstr. rend., 1905, 141, 56—58.)

When the gluten of white flour is readily separated by washing and kneading the cake of dough under a stream of water, in the case of "whole meal" flour, or mixtures of the same with white flour, a coherent mass is often cannot be obtained. This is probably due to the admixture of the coarser quality of flour, to the presence of mucilaginous substance in the latter, and to the fact that it contains more glutenin and less gluten than

white flour. The finely divided bran, also, has the effect of preventing agglutination. The gluten extracted from flour containing only a small quantity of bran, is usually found to contain less nitrogen than is present in ordinary gluten. This is accounted for by the fact that the bran is separated along with the gluten. Owing to their lack of agglutinating power, whole meal or inferior flours do not "rise" well in bread-making. —W. P. S.

ENGLISH PATENT.

Food-stuffs for Cattle or other Live Stock; Manufacture of —. C. Beadle and H. P. Stevens, London. Eng. Pat. 14,588, June 29, 1904.

COTTONSEED hulls or other material containing difficultly digestible fibre are thoroughly mixed with about 5 per cent. of their weight of hydrochloric acid (sp. gr. 1.16) and heated in a closed vessel, provided with a stirrer, to a temperature of 212°—300° F. The amount of acid to be added depends on the material employed and on the duration of the heating. By heating for 30 minutes, the above percentage of acid is required, but the quantity may be reduced if the heating be prolonged. After heating, the substance is ground and at the same time mixed with some basic substance such as sodium carbonate, chalk, cottonseed kernel meal, &c., to neutralise the acid. During the heating, the acid vapours coming from the mixture may be led into a second quantity of material contained in a separate vessel, air being drawn through both vessels to facilitate the removal of the acid vapours.—W. P. S.

UNITED STATES PATENTS.

[Milk] Separator; Centrifugal Liquid —. E. C. Pawley, Chicago, and A. W. Ruwell, Sycamore, Ill. Assignors to Smith Manufacturing Co., Chicago, Ill. U. S. Pat. 793,222, June 27, 1905.

A CORRUGATED, perforated skimmer is mounted upon an inward projection in the bottom of the bowl of the centrifugal separator. The skimmer is provided with a frustum-shaped cap and the bowl has a cover in which outlets are arranged for the "blue milk" and cream.—W. H. C.

Fruit; Process of Preserving —. D. F. Sherman, Chicago. Assignor to California Concentrated Fruit Co. U. S. Pat. 793,614, June 27, 1905.

THE fruit is mashed and reduced to a pulp, the coarser part of the fruit being separated. The mixture of fine pulp and juice is then concentrated under reduced pressure, and the product pressed into blocks, which are finally completely dried. A "binding" material may be added to the pulp before concentrating.—W. P. S.

Fruit Product; Preserved —. D. F. Sherman, Chicago. Assignor to California Concentrated Fruit Co. U. S. Pat. 793,615, June 27, 1905.

THE product claimed is obtained by concentrating fruit pulp under reduced pressure, with or without the addition of a binding material, until a solid product results. (See preceding abstract.)—W. P. S.

FRENCH PATENTS.

Albuminous Substance from Maize; Extraction of an —. E. Donard and H. Lalbé. Second Addition, dated Jan. 5, 1905, to Fr. Pat. 320,027, March 28, 1902. (This J., 1902, 1548.)

THE albuminous substance obtained as described in the original patent may be dissolved in a solvent such as ethyl alcohol, amyl alcohol, acetone, &c., and applied as a varnish or coating to articles of food, pills, &c., to prevent them attracting moisture or becoming oxidised. Pills so coated are not dissolved until they reach the intestines.—W. P. S.

Oils; Process for Preparing Alimentary or other —, and Alimentary Products by means of these Oils, and the Products Resulting from these Processes. J. E. Bloom. Fr. Pat. 351,142, Jan. 26, 1905.

SEE U.S. Pats. 782,820 and 782,821 of 1905; this J., 1905, 341.—T. F. B.

Bread Products containing Iron: Process of Making —. C. Aufsberg. Fr. Pat. 351,213, Feb. 1, 1905.

SEE Eng. Pat. 27,266 of 1904; this J., 1905, 207.—T. F. B.

Alimentary Product; New —. Soc. B. Henneberg et ses Fils. Fr. Pat. 351,291, Feb. 6, 1905.

THE product consists of curd (caseum) from which all bacilli have been eliminated, except the species termed "bacilli bulgare."—W. P. S.

Milk; Process of Making Dried —, and Products containing Milk Albumin. J. R. Hatmaker. Fr. Pat. 351,298, Feb. 6, 1905. Under Int. Conv., Feb. 12, 1904.

SEE Eng. Pat. 3531 of 1901; this J., 1905, 206.—T. F. B.

(B).—SANITATION; WATER PURIFICATION

ENGLISH PATENT.

Water; Methods and Means for Purifying, Softening and Treating —. Mather and Platt, Ltd., and E. Hopkinson, Manchester. Eng. Pat. 17,994, Aug. 19, 1904.

THE hard water is led into a tank divided into two compartments by a partition, in which are arranged two adjustable weirs, one placing the two compartments in communication with each other, and the other allowing the water to flow into a lime tank. Alkali is supplied from a tank into a tipping basin in one compartment, connected with a ball-float in the other compartment. The level of the alkali in the basin is regulated by a ball-cock, and the quantity of alkali added to the water is governed by a slit in the side of the basin and by the action of the ball-float. A portion of the hard water, after passing over one of the weirs, enters a chamber where it comes in contact with a layer of lime, and then flows down a pipe to the bottom of a tank. The nozzle of the pipe is provided with baffle plates. In this tank any excess of lime settles out, and the water then passes from the top of the tank down a pipe, where it meets the main supply of water already treated with alkali. Both supplies enter a settling tank through a helical pipe, and from the top of this settling tank the softened water is led into a second settling tank provided at the top with a dished plate on which are placed a layer of jagged metallic bodies, and a layer of filtering material, such as peat. The softened water is finally drawn off below this filter, but above the dished plate. In an alternative apparatus described, only one settling tank is employed, and the supply of water to the lime tank is regulated by a water-wheel, and revolving stand pipe.—W. P. S.

FRENCH PATENT.

Chlorine or Oxygen Compounds of Chlorine: Process of Eliminating —, from Water designed for Drinking, Industrial or Agricultural Uses. G. Demoussy. First Addition, dated Jan. 14, 1905, to Fr. Pat. 339,163, Nov. 12, 1903. (This J., 1905, 49.)

MAGNETIC iron oxide, cobalt oxide or manganese oxide may be employed for reducing the chlorine compounds in the water.—W. P. S.

(C).—DISINFECTANTS.

UNITED STATES PATENT.

Fungicide and Method of Making same. F. J. Smith, Elizabeth, N.J., Assignor to American Agricultural Chemical Co., New York. U.S. Pat. 794,644, July 11, 1905.

PHOSPHORIC acid is added in excess to a solution of copper sulphate, the product is neutralised with lime, dried, pulverised and mixed with calcium arsenate.—T. F. B.

FRENCH PATENTS.

Antiseptic; Fluorescent —. E. Turpin. First Addition, dated Jan. 24, 1905, to Fr. Pat. 346,363, Sep. 20, 1904. (See this J., 1905, 148.)

THE bromofluoresceins in general, and Eosin in part are found to have antiseptic properties superior to that of Fluorescein itself; di- and tetranitrofluorescein mono- or diethylfluorescein, as well as its chloro and derivatives all possess antiseptic properties, and application for disinfectant purposes is claimed.—T. F. B.

Sulphur; Process for Making — easily Miscible with Water for the Anticryptogamic Treatment of Vegetables. E. Mauriat. Fr. Pat. 351,306, Feb. 6, 1905.

By adding to sulphur about 8 per cent. of gum, dextrin, starch, molasses, glucose, gelatin, glue or similar product it can be easily mixed with water to form a paste or suspension suitable for the treatment of vegetable diseases.—T. F. B.

XIX.—PAPER, PASTEBOARD, Etc.

Paper; Use of Higher Fatty Amides in Sizing. A. Müller-Jacobs. Z. angew. Chem., 1905, 58, 1141—1143.

THE use of rosin-soaps for sizing has almost superseded other methods, though the durability of papers sized by this process has lately been severely questioned. According to Wurster, the active agent in this process is not rosin-soap itself, but rosin in an extremely fine division, produced possibly along with basic aluminium sulphate by reaction of excess of alum on the rosin, perhaps partially by the reaction on the resinic, boric acid contained in the large quantities of water used. Similarly beeswax-soap, when used, probably acts by means of very finely divided myricyl alcohol in a similar way. The author has found that *stearamide*, prepared by heating ammonium stearate under pressure at 100° C. can be dissolved in water by long boiling with so much more rapidly when a little sodium carbonate is added. The hot solution is clear and viscous, and when diluted, becomes milky. This milky liquid contains the stearamide in suspension in a state of such fine division that it does not deposit even after months of standing, and by adding metallic salts to the liquid, the corresponding metallic soaps are deposited in a flocculent form, the stearamide settling out at the same time. For the deposit it can be separated by digestion with alcohol or any other solvent which does not dissolve the soap. The pure substance melts at 109° C., is not destroyed by acids, alkali hydroxides or carbonates, and is not attacked by light, air, or moisture. It can be used with the advantage in sizing paper; for 150 tons of dry pulp of stearamide are dissolved in a solution of 0.8—1.0 ton of good soap and 0.2 ton of soda crystals in 10—15 tons of boiling water, strained through a cloth, and added to the pulp in the hollander with a solution of 1—2 tons of alum or the corresponding quantity of aluminium sulphate. In the subsequent calendering, the stearamide is deposited, which further improves both the appearance and the water-resisting power of the paper. The process is cheap and simple, sizing with wax, though it is not applicable to the same varieties of paper; and it will probably be found to be the reproach of lack of durability cannot be levelled against it in this way.—J. T. D.

Parchment Paper; Methods of Testing the Impermeability of — to Fats. C. Bartsch. Papier-Zeit., 1905, 2190.

THE so-called "blister test" is frequently used as a means of determining whether or no parchment is grease proof. It consists in heating parts of the parchment to a flame and noting whether blisters are produced to the impermeability of the outer layers of parchment, allowing the steam formed in the interior to escape sufficiently rapidly. Turpentine oil is also frequently employed as a reagent, and samples of parchment

when rubbed with a few drops of that liquid allow to pass are regarded as being grease proof. Since these methods are simpler than those officially adopted, the author has made comparative practical tests on sheets of parchment paper of different origin and weight. In the actual tests with fats, small portions of paper and bacon were wrapped in pieces of the parchment paper of about 10 by 15 cm. in size, a piece of paper then wrapped round the outside, and the whole pressed flat and kept at 18° to 20° C. for 24 hours, after which the writing paper was examined to see whether there were any grease spots. In the turpentine tests the paper was vigorously rubbed with four or five drops of turpentine oil, applied by means of the brush. The results, given in tabular form, show a close correspondence between the results of this test and the practical tests with fats. In some cases papers that were found to be lard or butter allowed fat from the bacon which is to be attributed to the fact that a certain amount of that fat separates in the liquid state at from 18° to 20° C.; but in such cases the paper was also porous to turpentine oil. As a general rule the blister test also gave corresponding results with the fat tests, but this was not always the case. In the author's opinion the turpentine test has the advantage of detecting the presence of the defects that frequently occur in parchment paper, which they are not shown by the blister test.—C. A. M.

ENGLISH PATENTS.

Pulp Strainers; Impts. in Oscillating Cylindrical Strainers. H. Sanguinetti, London. Eng. Pat. 16,245, 1904.

Several partitions of an oscillating straining cylinder or cellulose manufacture are provided with means to equalise the pressure within the cylinder. The partitions are of a conical or doubly conical shape, in each case the greatest diameter being at the centre, so as to facilitate the discharge of the material. Claim made for the construction of a pocket provided with a large valve, in the lowest portion of the vessel in which the cylinder works.—W. H. C.

Imitation of White Horn, Buffalo Horn, Tortoise Shell, Ivory, Mother of Pearl and the like. T. Puy-Guillaume, France. Eng. Pat. 22,245, 1904. Under Int. Conv., Nov. 3, 1903. Eng. Pat. 336,970 of 1903; this J., 1904, 453.—T.F.B.

Acetates; Process for Directly Converting Cotton into Acetate. Fabr. de Produits Chimiques Flora Soc. A. Dübendorf, Switzerland. Eng. Pat. 9998, May 1905. Under Int. Conv., Aug. 23, 1904. Eng. Pat. 345,764 of 1904; this J., 1905, 40.—T.F.B.

Manufacture of —. A. Béhal, Paris. Eng. Pat. 11,512, June 1, 1905.

Cells are found to possess the property of forming nitrocellulose homogeneous compounds resembling cellulose, in presence of suitable nitrocellulose solvents. The product, consisting almost entirely of isoborneol, is obtained by the hydration of camphene, is especially adapted for this purpose. One kilo. of nitrocellulose is mixed with a sufficient quantity of alcohol of 96 per cent strength, and is mixed with a solution of 500 grms. of isoborneol dissolved in 500—600 grms. of ethyl acetate; the mixture is submitted to centrifugal action, or deprived of solvent in any other convenient way. Camphor may be substituted for a portion of the borneol if desired.—T. F. B.

UNITED STATES PATENT.

Boards; Apparatus for Drying. W. R. Hope,ignor to the E. I. Du Pont de Nemours Powder Co., Wilmington, Del. U.S. Pat. 793,374, June 27, 1905.

Boards are dried between frames with battens on their faces which converge together, and when the frames are moved in position for drying, come into contact with

rollers arranged vertically in paired sets, at varying distances apart, in such a manner as to form a wedge-shaped container for the frames. As the boards contract, the holding-frames gradually move downwards, so that a constant and uniform pressure is maintained upon the boards. The frames carrying the rollers are secured to stanchions upon the framework of a car, which is mounted upon wheels.—E. B.

FRENCH PATENTS.

Size suitable for Paper and for Paints of the Nature of White Wash. Le Fibrocol. Fr. Pat. 349,885, April 30, 1904.

A sizing suitable for paper is obtained by mixing 5 parts of viscose (containing 12 per cent. of cellulose) with 3 parts of a solution of casein (mixed with 10 per cent. of its weight of borax) in 5 times its weight of water. This product, may, if desired, be mixed with barium sulphate, kaolin, or similar material. If it be desired to prepare a sizing for mixing with paints, the best proportions are viscose (containing 5 per cent. of cellulose) 1 part; casein dissolved with 20 per cent. of borax, in five times its weight of water, 1 part. This can be mixed with kaolin and "asbestine" in the following proportions:—Viscose-casein size, 13 parts; "asbestine," 10 parts; kaolin, 3 parts. The mass is thoroughly mixed, and 1 per cent. of formaldehyde is added as a preservative.—T. F. B.

Celluloid or Collodion Sheets of Variable Thickness; Process of Making —. Act.-Ges. f. Anilinfabr. Fr. Pat. 349,884, April 30, 1904.

See Eng. Pat. 9962 of 1904; this J., 1905, 248. T. F. B.

Celluloid; Process of Making Non-inflammable Substances Resembling —. P. A. D. Prost and E. Mickey. Fr. Pat. 351,555, Jan. 17, 1905. Under Int. Conv., March 14, 1904.

NITROCELLULOSE is dissolved in acetone, ether-alcohol, or other solvent in which has been dissolved a sufficient quantity of a metallic salt to render the final product non-combustible. Such salts are alum, zinc chloride, aluminium chloride, &c.; the solution is run into suitable moulds, which are placed in a heating chamber connected with a condenser. The products are stated to be translucent and non-combustible, and to be useful as substitutes for celluloid. The finished articles may be further treated with a solution of an alkali carbonate or silicate, to precipitate a superficial layer of metallic carbonate or silicate on the object.—T. F. B.

Cellulose Xanthate; Use of — for the Manufacture of Substitutes for Wood, Horn, etc. Soc. Franc. de la Viscose. Fr. Pat. 351,089, Jan. 28, 1905.

CELLULOSE xanthate, obtained by the action of carbon bisulphide on alkali cellulose, is allowed to harden by standing at the ordinary temperature for a day or two, when it is ground between cylinders in the cold for about half an hour, until it has become perfectly smooth. After standing for about 24 hours, the soluble xanthate is passed into a suitable press, where it is compressed into a homogeneous mass, which is introduced into suitable moulds, and then "fixed" by keeping it for 24—36 hours at a temperature of about 30° C. The product is stated to be quite homogeneous, of even density throughout, and free from cavities, &c. It can be moulded to the desired shape and coloured or otherwise treated to resemble wood, horn, &c.—T. F. B.

Cellulose Products formed by the Decomposition of a Solution of Cellulose by means of Bases; Process of Making —. Verein. Glanzstoff-Fabriken, Act.-Ges. Fr. Pat. 351,206, Feb. 1, 1905.

SOLUTIONS of cellulose in ammoniacal copper solutions are forced through small orifices into solutions of bases, such as sodium or potassium carbonate, washed and dried under tension. The products are said to contain copper, and to have much greater resistance to water than when acids are used as the coagulating agents. The copper may be removed from the products, if desired, by treatment with sulphurous or chromic acid.—T. F. B.

Horschair; Process of Making Artificial — of Great Elasticity and Possessing the Transparency of Glass, also Films of the same Nature. Verein. Glanzstoff-Fabriken Act.-Ges. Fr. Pat. 351,207, Feb. 1, 1905.

THE threads or films containing copper, described in Fr. Pat. 351,206 (see preceding abstract), are immersed for about 15 minutes in a "concentrated" solution of sodium carbonate, containing 2 to 6 per cent. of ammonia; it is stated that under this treatment the material acquires considerable elasticity, tenacity and transparency. It is then washed and freed from part or all of the copper it contains, and finally dried under tension. Films made by this process can be used for photographic purposes or as textile substitutes, whilst the threads, after carbonisation, are of use as filaments for incandescent electric lamps. —T. F. B.

Cellulose Threads and Films; Process of Making Elastic Tenacious and Transparent —. Verein. Glanzstoff-Fabriken Act.-Ges. Fr. Pat. 351,208, Feb. 1, 1905.

THE threads or films obtained by forcing "cellulose cuprammonium" through orifices or thin slits into a coagulating medium which will remove the copper and ammonium compounds (e.g., 35 to 60 per cent. sulphuric acid), are wound on a cylinder, which is caused to rotate in a "concentrated" solution of sodium carbonate. The product is washed with water containing a little acetic acid until free from alkali, and then dried under tension. The resulting threads or films are stated to be very tough and elastic, and as transparent as glass. (Compare Fr. Pat. 350,206, above.)—T. F. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

Cinnamyl Alcohol (Styrone); Conversion of Cinnamic Aldehyde into —. P. Barbier and G. Leser. Bull. Soc. Chim., 1905, 33, 858—859.

CINNAMYL alcohol cannot be obtained by the direct reduction of cinnamic aldehyde, since the latter polymerises. The diacetyl derivative of the aldehyde, obtained by the action of acetic anhydride, may, however, be easily reduced by means of iron in acetic acid solution. The product is diluted and extracted with ether, and the ethereal extract distilled, the distillate between 120° and 160° C. (14 mm.) being saponified, and the product fractionated. The yield of alcohol amounted to about 20 per cent. of the aldehyde used.—T. F. B.

Antipyrine; A Compound of Mercuric Oxide with —. C. Astre and J. Ville. Bull. Soc. Chim., 1905, 33, 842—845.

By heating 20 grms. of mercuric oxide with a solution of 50 grms. of antipyrine in 500 c.c. of water for 6—7 hours at 100° C., a white crystalline mass is obtained, which, when dry, has the composition $(C_{11}H_{12}N_2O)_2HgO_2H_2$; its m. pt. is 195°—196° C., it is sparingly soluble in water, ether and benzene, easily soluble in alcohol and chloroform. Its aqueous solutions do not exhibit the properties of mercuric salt solutions, but they give the reactions of antipyrine. Its general properties indicate that its constitution is—

By passing hydrochloric acid gas into its saturated chloroform solution at the ordinary temperature and at 40° C., hydrochlorides containing three and four molecules of hydrogen chloride respectively are produced.—T. F. B.

Alkaloids; Formation of — in Plants. A. Pictet. Arch. Sci. phys. nat., Genève, 1905, 19, 329—352.

THE view generally held at the present time with regard to the formation of the alkaloids, is that they are the nitrogenous waste products of the metabolism of the plant, resulting from the partial decomposition of more

complex substances. Certain species of plants have power of destroying these waste products, and in them no alkaloids are found. In those plants which have the power of destroying the alkaloids, the latter are stored up in certain cells or special tissues where they do not impede the general activity of the vital functions of the plants. Before being stored up in such special tissues, however, the waste products, in general, undergo chemical change within the plant, the effect being to render them less injurious. The following facts are in favour of this view:—(1) In most alkaloids, the molecule is composed of two distinct parts, viz., a central nitrogenous nucleus to which are connected by intermediary atoms of nitro or oxygen one or more secondary groups of an entirely different character. (2) When several alkaloids are present in the same plant, the central nucleus is the same in all the compounds, the differences being due to the nature or nature of the secondary groups. (3) Very few alkaloids contain free hydroxyl or imino radicals; in most the hydrogen of these radicals is replaced by a group. The secondary groups which enter into the molecule of the nitrogenous waste products to form alkaloids, vary in different cases. In a few instances, a dextrose enters the molecule, the alkaloids formed being glucosides, e.g., solanine, achilleine, and sinalbino. Frequently the group introduced is an acyl group, for example, cocaine and aconitine (benzoyl), atropine (tropyl or α -phenylhydroxypropyl), piperine (piperidinyl), sinapine (sinapyl), pseudo-aconitine and veratrine (veratryl), colchicine (acetyl), and veratrine (angeloyl or α -methylisocrotonyl). In by far the largest number of cases, however, one or more methyl groups are introduced which saturate the hydroxyl and imino groups. In other cases, variations occur in the case of piperine, narcotine, narceine, hydrastine and berberine, where a methylene instead of a methyl group is introduced. The author regards the methylating agent, the formaldehyde, which is found in the green portions of the plant by the action of carbon dioxide on carbon dioxide in presence of light and heat. The formation of methyl and methylene derivatives may be expressed by the equations:—

In respect to the central nitrogenous nuclei, all may be divided roughly into four classes:—(1) those containing a pyridine, piperidine or quinoline nucleus;

(2) those containing a pyrrol nucleus, $N < \underset{C}{\underset{C}{C}} >$ associated with a pyridine or benzene nucleus; (3) those containing a purine nucleus, $N < \underset{C}{\underset{C}{C}} - N < \underset{C}{\underset{C}{C}} >$ associated with a pyridine or benzene nucleus; (4) those containing a pyrazine nucleus, $N < \underset{C}{\underset{C}{C}} - N < \underset{C}{\underset{C}{C}} >$.

A number of non-cyclic quaternary bases contain the group $(CH_3)_3N.C.C.C.$; such as choline, betaine, &c. Of these classes of alkaloids, evidence is adduced indicating that those containing a purine nucleus and those belonging to the choline group result from the partial decomposition of vegetable nuclein and lecithin respectively. Alkaloids containing a pyrrol nucleus are produced by the decomposition of albuminoid substances; and those containing pyridine, piperidine or quinoline nucleus are formed indirectly from albuminoids, the pyrrol or quinoline nuclei in the latter being first methylated, and then undergoing chemical transformation into pyridine, piperidine or quinoline nuclei. The author has proved experimentally that methylated derivatives of pyrrol and indole can be converted into pyridine and quinoline derivatives.

Sparteine; Action of Ethyl Iodide on —. C. Jurek and A. Valeur. Comptes rend., 1905, 141, 49—

WHEN ethyl iodide and sparteine are heated together, sparteine hydriodide is formed, ethylene being liberated, according to the equation: $C_{26}H_{34}I + C_{15}H_{26}N_2 = C_{14}H_{18} + C_{12}H_{16}N_2.HI$. In alcoholic solution, the action is more rapid, sparteine hydriodide and two isomeric iodo-ethyl derivatives being formed. (See also this J., 1905, 813.)—W. L. S.

leaves; Presence of a Glucoside of Hydrocyanic in —. E. Bourquelot and E. Danjon. *Comptes* 1905, 141, 59—61
 ting elder leaves according to the method previously d by one of the authors (this J., 1904, 1244), being employed, it was found that they contain ide. Dextrose, hydrocyanic acid and an aldehydic co were obtained, showing that the glucoside ed amygdalin, if it were not the latter itself. Hydrocyanic acid has not been detected in these before, is due to the fact that they contain no . Only on acting on the leaves with emulsin hydrocyanic acid set free.—W. P. S.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Homocol as a Sensitiser; Properties of —. A. J. Newton, C. E. K. Mees and S. E. Sheppard. *Phot. J.*, 1905, 40, 264—267.

THE absorptions of solutions of Homocol (1 in 20,000) both in presence and in absence of ammonia, and the colour sensitising action on plates are given in tables and curves. A series of experiments made by Eder's method to determine the ratio of blue sensitiveness to yellow sensitiveness (viz., by exposing plates behind screens made to divide the spectrum at wave length 4900, so that one screen transmits all the yellow and green rays, and the other the rays from wave length 4900 downwards), gave this ratio as 1.1 to 1.4; plates bathed with Erythrosin give 12 to 20; "good" panchromatic plates, 5—10; plates with subdued blue sensitiveness, 2—5. The ratios with Pinachrome and Pinaverdol were 1.1 and 2.1 respectively. The Homocol plates were freer from fog than those bathed with the two last-named dyestuffs.—T. F. B.

Photographic Processes; The Theory of —. II. The Chemical Dynamics of Development; including the Microscopy of the Image. S. E. Sheppard and C. E. K. Mees. *Proc. Roy. Soc., A*, 1905, 76, 217—234.

By constant development for a short time, the depth of the image (in the emulsion) is independent of exposure; by increasing the time of development, the depth increases to a maximum for each exposure, and then becomes constant. When the degree of development (γ) is low the size of the grain of reduced silver increases with the exposure; as the time of development increases, the size of grain does also, until at γ_{∞} it is independent of the exposure; addition of bromide causes a diminution in the size of the grain (see also this J., 1904, 799). At moderate degrees of development, the number of grains of silver on the surface of the film is constant; in the thickness of the film, the number of grains increases with the exposure and degree of development to a maximum. By exposing plates through the glass side, it was ascertained that the grains receiving most exposure start developing first, and are thus most active. With constant exposure, and within certain limits, the velocity of development varies as the concentration of the developer. In most cases it is found that hardening agents have no influence on the development velocity of an emulsion; thus a plate was immersed in a 4 per cent. solution of formaldehyde until the film became quite insoluble in boiling water, but the development velocity of the emulsion was found to be undiminished.—T. F. B.

Erdmann's Salt as a [Photographic] Reducing Agent: Some Results with ——. S. E. Sheppard. Phot. J., 1905, 40, 267–269.

EXPERIMENTS on the reducing action of a solution of Erdmann's salt, prepared as indicated by Smith (see this J., 1905, 635), on negatives made from slow plates of varying densities, showed that at first the reducing action was slight, and very little selective, but after longer action the reduction was more rapid, and selective to the lower tones. This is contrary to Smith's results. In the case of a fast plate the reduction was found to increase somewhat with the density, so that the action of Erdmann's salt is not constant, owing partly to the variation of the size of the grain, due to different conditions of exposure and development. (See Lumière and Seewetz: this J., 1904, 799.)—T. F. B.

XXII.—EXPLOSIVES, MATCHES, Etc.

Explosives; Twenty-ninth Annual Report of His Majesty's Inspectors of ——. 1904. (See under "New Books.")

Modifications of the Law.—There have been two modifications during the course of the year, taking the form of orders of the Secretary of State; the one regulating the deposit of explosives in dust-bins, &c., for conveyance as rubbish, the other consolidating and re-arranging the regulations in regard to the packing of explosives for conveyance.

Accidents.—The number of deaths (13) from accidents in the manufacture of explosives is considerably above the average for the decade (7.5).

Factories.—The total number of factories under continuing certificate or license is 148.

Importation.—

	1903.	1904.
	lb.	lb.
Nitroglycerin explosives ..	2,330,582	2,244,723
Ammonal	154 & 2 cases	325
Castropite	14	—
Picric Acid	—	252,256
Titanite	—	25
Detonators (number)	17,313,975	15,279,412

Of the above quantity of nitroglycerin explosives imported during 1904, 1,759,652 lb. were transhipped for other countries.

Dr. Dupré's Report.—Out of 417 samples examined, 66 were rejected. The number of rejections is rather higher than usual, due mainly to the high proportion of samples rejected in the case of a small number of explosives. In connection with an accident which occurred in the manufacture of a cap composition, it was found that the electrolytic plumbago used, contained a very appreciable quantity of free sulphuric acid, an ingredient known to be highly dangerous in chlorate mixtures. Further experiments

were made with the vapour tension test for the stability of explosives (this J., 1904, 727). Samples of caps returned from stations abroad, on account of low test, were submitted to the test, which in all cases passed satisfactorily. If future experience should confirm these results, the test will have proved itself capable of deciding whether a low heat test shown by cordite indicates danger or not, and, so far, is the only test among those proposed which is apparently, like the heat test, directly applicable to nitroglycerin explosives. An examination was also made of the Bergmann and Junk test, (this J., 1904, 953). It was found that duplicate experiments gave very concordant results, but that the test was influenced to a considerable degree by variations in the percentage of moisture in the samples tested, more especially the sample was not perfectly purified. An investigation of the temperature of explosion showed that differences between the temperatures of the exploding points of samples differing widely in purity are too small to allow of discrimination by means of this test between samples differing but slightly. Many experiments were made to determine the varying conditions influencing the test, and to fix as far as possible the precise conditions under which it should be carried out. It is considered for the purposes of the department, which deals exclusively with explosives of recent manufacture, that the heat test, when carefully carried out, is well qualified to decide whether these explosives have or have not been sufficiently purified. Moreover, the heat test is the only test advanced which is at all capable of being applied in a satisfactory manner with the great variety of explosives contained in the authorised list.

Woolwich Testing Station.—Captain Desborough reports that out of 18 explosives submitted to the official test, in seven cases the tests were successful. Experiments undertaken to determine whether an explosive, surrounded by a material which is a relatively bad conductor of heat, is likely to be affected as regards its liability to fire the gas mixture, showed that high explosives are not affected, but with slow explosives, the indications that a decided effect is produced. A few experiments appended to the report giving an account of the ignition of fire-damp, which have arisen from the use of explosives which have passed the test now in force.

The following specific dangers are pointed out:—

(1.) Danger of firing two shots within a short interval of time without an examination for gas being made after the firing of the first.

(2.) Danger of overcharging, more particularly with slow explosives.

(3.) Danger of firing a shot in a hole in which a crack or fissure exists.—G. W. McD.

UNITED STATES PATENT.

Explosive Composition. H. Boyd, London. U.S. Pat. 794,583, July 11, 1905.

FRENCH PATENT.

Explosives; Process for the Manufacture of — Danger when required for Use. Soc. Franc. des Poudres de Sécurité. Fr. Pat. 351,289, Feb. 6, 1905.

IN order to avoid any danger in the transport or use of explosives, the combustible and oxygen-yielding constituents are kept separate and are mixed only when the explosive is required for use. The following are suitable mixtures of combustible substances:—(1) *o*-Nitrotoluene, 27; mononitronaphthalene, 9 and dinitronaphthalene, 64 parts. (2) Paraffin wax, 35; *o*-nitrotoluene, 50; and trinitrotoluene, 15 parts. (3) Paraffin wax, 23; *o*-nitrotoluene, 13; trinitrotoluene, 13; and iron filings, 51 parts. The mixture (1) is intended for use with the nitrates of ammonium, aniline and potassium; whilst (2) and (3) are suitable for use with potassium chlorate. When required for use, the combustible composition is liquefied by warming to about 100°C. and then mixed with the nitrate or chlorate.—A. S.

INORGANIC—QUALITATIVE.

Antimony and Tin; Separation of — O. Arne. Rep. Congress Chim. Pharm. Liege, 1905, 75.

Method proposed relates to the separation of arsenic, antimony and tin, and is applied to the sulphides of these metals, after the said sulphides have been separated from the sulphides of other metals by means of ammonium chloride. The solution of the sulphides in the latter is treated with hydrochloric acid, and the precipitate collected on a filter and washed. A portion of the precipitate is dissolved with a 2 per cent. solution of borax and a few drops of 10 per cent. ammonium chloride, when the arsenic chloride is dissolved. After cooling, the solution is treated with the arsenic trisulphide re-precipitated in the filtrate by the addition of an excess of tartaric acid and ammonium chloride. The precipitate, consisting of antimony and tin sulphides, remaining on the filter, is washed with the solution of borax and ammonium chloride, and is then boiled with a 5 per cent. sodium carbonate solution containing ammonium chloride. The antimony trisulphide goes into solution and is filtered off. The separations appear to be exactly quantitative, each separated metal being contaminated with a trace of the other metal. —W. P. S.

INORGANIC—QUANTITATIVE.

Hydroxylamine; Quantitative Separations by means of
in Ammoniacal Solution. P. Jannasch with F. Rühle, J. Cohen, and J. Schilling. J. pr. Chem. 1905, 72, 113, 14—26, 26—34, 35—37.

If these separations depend on the precipitation of hydroxides of certain of the metals by ammonia in the presence of hydroxylamine, and the retention in solution of the hydroxides of other metals. The outline of the method is as follows:—The substance (0.3—0.5 gm.) dissolved in hot water with 5 c.c. of hydrochloric acid, and sufficient hydroxylamine hydrochloride (say 5 to 10 c.c.), but experience will soon show the most appropriate quantities in each case) is added, the solution heated to boiling, and excess of ammonia added very cautiously and gradually, the operation being conducted in a tall, narrow beaker, on account of the evolution of nitrogen. The whole is heated on the water-bath till the precipitate has settled well, the clear liquid decanted through a filter, the outer paper of which is larger than the beaker, the precipitate washed once or twice by decantation, and then on to the filter, and washed thoroughly. Individual peculiarities are mentioned under the several separations. In all cases, the quantitative accuracy of the method was proved by experiments with the pure substances before attempting separations.

Iron from Manganese.—After precipitation by say 10 c.c. of strong ammonia (very cautiously, as the evolution of gas is stormy), the solution is heated for half an hour on a water bath, the clear liquid decanted, the precipitate dried once or twice, collected on the filter, drained, and filtered off into the original beaker with hot dilute hydrochloric acid, and reprecipitated as at first, using only 3 c.c. of hydroxylamine salt. The precipitate is dried well on the filter, dried, ignited, and weighed. The precipitate should be absolutely free from manganese dioxide. The filtrates are evaporated, the residue dried gently to expel ammonium and hydroxylamine

salts, and then dissolved in hydrochloric acid for the determination of the manganese by precipitation with hydrogen peroxide or by other methods.

Iron from Magnesium.—The process is exactly as above, and a second precipitation is always necessary. It is found that the presence of the ammonium and hydroxylamine salts does not interfere with the precipitation of magnesium by sodium phosphate, so that it is not necessary to expel them.

Aluminium from Manganese.—The details are as above, but a single precipitation with about 25 c.c. of ammonia effects complete separation, and the ignited alumina is absolutely white. (In all these ammonia precipitations, it is unnecessary to avoid the presence of excess of ammonia or to expel such excess, as is the case when hydroxylamine is not present.)

Aluminium from Zinc.—The separation is carried out exactly as the immediately preceding separation, save that a few grams of ammonium chloride are added before the ammonia. After evaporation of the filtrates, bromine water is added to destroy the salts of hydroxylamine, lest zinc should be reduced and volatilised during the expulsion of the ammonium salts.

Aluminium from Nickel.—The aluminium is precipitated as above. The ammonium and hydroxylamine salts must be expelled by ignition before precipitating the nickel with sodium hydroxide. Mere boiling of the concentrated filtrates with sodium hydroxide does not give complete precipitation of the nickel.

Aluminium from Magnesium.—The separation is effected exactly as that of iron from magnesium, save that a single precipitation is enough.

Chromium from Manganese.—About 40 c.c. of ammonia are used to precipitate; complete precipitation of the chromium occurs in the boiling liquid, even in presence of considerable excess of ammonia, and the precipitate after settling for half an hour on the water-bath filters rapidly and easily.

Chromium from Zinc.—Usually a single precipitation with 30 c.c. of ammonia gives complete separation, but in doubtful cases a second may be necessary.

Chromium from Nickel and Magnesium.—These separations are carried out exactly as in the corresponding separations from aluminium.

The reduction of chromates by hydroxylamine is very sharp and rapid, and greatly preferable to reduction by alcohol. The chromium hydroxide precipitated in the presence of hydroxylamine has no tendency to pass the filter, is readily washed, and does not carry down potassium or sodium salts. In all of these precipitations the presence of iodides or bromides (or the corresponding acids) has no noticeable effect on the precipitation; sulphuric acid renders the precipitate a little more difficult to wash; nitric acid, if present in considerable amount, destroys the effect of the hydroxylamine, and must be removed. Formic acid does not interfere with the process, but acetic acid and still more tartaric or citric acid, prevents complete precipitation.

Aluminium from Copper.—After precipitation, settling, and decantation of the clear liquid, 150 c.c. of water and 30 c.c. of neutral 5 per cent. ammonium acetate solution are added and allowed to stand on the water-bath for 15 minutes before decantation. The precipitate must be very thoroughly washed with boiling water, and ammoniacal water should be used to extract all copper from the filter. The ignited alumina must be pure white. The filtrates are boiled down to small bulk, and acidified with hydrochloric acid, when the liquid loses its colour through formation of cuprous chloride (hydroxylamine is much to be preferred to sulphurous acid as a reducer of cupric salts). To the warm liquid a 10 per cent. solution of ammonium thiocyanate is gradually added with constant stirring till precipitation is complete; after 6 hours the liquid is filtered and the precipitate carefully washed with cold water, dried, incinerated, and ignited in a stream of oxygen.

Chromium from Copper.—To the solution are added 3 c.c. of hydrochloric acid and 2.5 grams of hydroxylamine, and after reduction in the boiling solution, precipitation is effected by 15 c.c. of ammonia. After standing and decantation, the precipitate is washed, first with water

containing ammonium chloride, then with pure water. The rest of the process is as above.

Iron from Copper.—To the solution (200 c.c.) is added hydroxylamine in quantity about five times equivalent to the iron present, then 5 c.c. of hydrochloric acid, and the whole is then boiled till decolorised. About 15 c.c. of ammonia, very gradually added, suffice for precipitation. For washing, both by decantation and on the filter, water alone is used.

Iron from Zinc.—The process is carried out as for copper; but a little ammonia is used in the wash-water, and the washing should not be continued longer than necessary.

Thorium from Uranium.—The process is carried out as in the general description. The thorium is completely precipitated as hydroxide, and weighed, after ignition, as dioxide. If chlorides be present the ammonium and hydroxylamine salts must be expelled from the filtrate, but if only nitrates the filtrates may be at once evaporated and the residue ignited. The ignited residue is weighed as U_3O_8 , then ignited in hydrogen and again weighed as UO_2 . The separation of iron from uranium is carried out in exactly the same way.

Precipitation of Thorium by Organic Acids and their Salts.—When thorium nitrate is boiled with ammonium, sodium or potassium succinate, it is completely precipitated as basic salt, which yields thorium oxide on ignition. Acetic acid, tartaric acid, or their salts, give very imperfect precipitation.—J. T. D.

Sodium Hydroxide in Presence of Sodium Carbonate; Volumetric Determination of —. K. Novotny. Z. Elektrochem., 1905, 11, 453—455.

THE author has examined the method proposed by Lunge and Schmidt for the determination of sodium hydroxide in presence of sodium carbonate, and also the modification proposed by Treadwell. Lunge and Schmidt's method consists in first determining the total alkali by titration with a mineral acid, using Methyl Orange as indicator, and then the caustic alkali by titration with oxalic acid solution in presence of phenolphthalein, after precipitation of the carbonate with barium chloride. Treadwell's modification consisted in the substitution of hydrochloric for oxalic acid, in the second titration.

The author has found that barium carbonate suspended in pure water has an alkaline reaction—this being due, in his opinion, to solution and hydrolysis of the carbonate with formation of barium hydroxide. This chemical change can, to some extent, be avoided, by using a large excess of barium chloride, since by doing so, barium ions are present in sufficient amount and concentration, to suppress the solution and hydrolysis of the barium carbonate. As regards the titration of the solution containing barium carbonate, the author finds more correct results are obtained with hydrochloric acid than with oxalic acid. The excess of barium chloride required by the modified procedure, tends to obscure the sharpness of the end of the reaction when oxalic acid is employed, owing to the formation of barium oxalate. The removal of the barium carbonate from the solution by filtration before titrating with the standard acid, the author considers to be unnecessary.—J. B. C. K.

Cyanide Solutions; Determination of the Chief Constituents in —. J. E. Clennell. Eng. and Mining J., 1905, 79, 1230—1232.

THE following methods have been used successfully in the analysis of cyanide solutions obtained in the treatment of gold- and silver-bearing ore at the Redjang Lebong mine, Sumatra. The solutions contain from 0.15 to 0.20 per cent. of "total cyanide," calculated as potassium cyanide, together with thiocyanates, iron (as ferrocyanide) and small amounts of copper, manganese and selenium.

Determination of Gold and Silver.—A suitable quantity of the solution is evaporated in a dish made of lead foil. The dish and residue are scorified with the addition of a small quantity of borax, the lead button is cupelled, and the bead of gold and silver is parted in the usual manner. The presence of selenium interferes with the colorimetric tests of Cassel and Moir (this J., 1903, 1257), stannous chloride precipitating this element in the form

of a reddish-brown powder, which obscures the pink tint produced by the gold.

Determination of Thiocyanate.—The colorimetric method proposed by Sharwood (see this J., 1898, 928) is employed. The solution is acidified with hydrochloric acid, filtered and treated with ferric chloride, the colour produced compared with that given by a cyanide solution containing a known amount of thiocyanate and treated in the same way.

Determination of Iron (Ferrocyanide), Zinc and Copper.—The cyanide, thiocyanate and ferrocyanide are decomposed by heating 50 c.c. of the solution to boiling with 10 c.c. of concentrated hydrochloric acid, adding 0.5 gram of potassium chlorate, and continuing the boiling for 15 minutes. In the clear yellow solution, the metals are determined by ordinary methods, viz., iron by precipitation with ammonia and determination colorimetrically as thiocyanate, copper colorimetrically, and zinc by titration with ferrocyanide, using uranium acetate as indicator.

Determination of Calcium and Magnesium.—The solution is boiled with hydrochloric acid and potassium chlorate as described above, the heavy metals removed as sulphides, and the calcium precipitated as oxalate. In the filtrate the magnesium is determined as phosphate.

The free cyanide, total cyanide and protective cyanides are determined by the usual methods, and manganese by the colorimetric method previously described by the author (this J., 1905, 46).—A. S.

Copper and Zinc Cyanides; Electrolysis of —. [Part II. Determination of Copper and Zinc.] F. S. Z. Elektrochem., 1905, 11, 391—407. (For Part I, see this J., 1905, 739.)

IN the electrolysis of alkali cyanide solutions, platinum dissolved at the anode and deposited at the cathode; this must be taken into account in analytical work of this nature. The deposition of copper and zinc is hindered by the presence of potassium cyanide, the metal separation only progressing in so far as the oxidation at the anode removes the cyanide. The best condition for the decomposition of potassium cyanide is a slight alkalinity (about 0.2 N.) of the solution. With wire gauze electrodes the electro-deposition of zinc from alkaline, cyanide solutions is capable of being used with accuracy as an analytical method, since with these electrodes the tendency to form spongy zinc is much diminished. On the other hand, cyanide solutions are chiefly of use where, for analytical purposes, electrolytic metal separations have to be carried out.—R. S. H.

Building Materials; Determination of Porosity of —. W. Thörner. IX., page 846

ORGANIC—QUALITATIVE.

Olive Oil Extracted by Carbon Bisulphide; Determination of — in Expressed Olive Oils. G. Halphen. Pharm. Chim., 1905, 21, 54—56.

OILS extracted by means of carbon bisulphide invariably contain sulphur or sulphur compounds, which when treated with sodium hydroxide solution are partially converted into thiosulphates. The soap is separated from the solution by the addition of sodium sulphate or chloride, and on heating the acidified filtrate with silver nitrate a brown precipitate of silver sulphide is obtained. Certain olive oils, however, that have not been extracted with carbon bisulphide also give a brown deposit in this way, but the impurities that cause this can be eliminated by precipitation with copper sulphate in the following manner:—50 c.c. of the oil are heated in a porcelain basin to 110° C. and then mixed with 12 c.c. of a solution of 100 grms. of pure sodium hydroxide in 75 c.c. of water. The heating is continued with constant stirring until the frothing of the mass has subsided. The temperature should then be about 160° C. and the duration of heating ought not to have exceeded 7 to 10 minutes. The heating is now discontinued and the mass consolidated by stirring until the temperature has fallen to 110° C. and the soap is in a granular state. 200 c.c. of hot water

added and the whole continually shaken until the mass is cold, after which it is shaken with 100 c.c. of a saturated solution of sodium sulphate and subsequently with 100 c.c. of a 33.3 per cent. solution of copper sulphate, filtered. The filtrate should have a faint green color, and if not, should be treated with 0.2 c.c. of the sulphate solution and re-filtered. To 100 c.c. of the filtrate are then added 5 c.c. of a solution, containing 1 part of a 1 per cent. solution of silver nitrate with 5 parts by volume of glacial acetic acid, the whole gently heated to the boiling point, then cooled to cool, and treated with ammonia in slight excess. Olive oils extracted with carbon bisulphide give a precipitate, which may either collect at the bottom of the beaker or leave a black deposit on the paper when filtered. The author states that he has never obtained a reaction with any olive oil not extracted with carbon bisulphide, but has invariably observed it even when only a small quantity of such oil had been mixed with expressed oil. The method, of course, is only conclusive in the case of oils of cruciferous plants, which as is well known, contain sulphur.—C. A. M.

ORGANIC—QUANTITATIVE.

Glucose Syrups; Fermentation Methods for Examination of— von Raumer. Z. Unters. Nahr. u. G. 1905, 9, 705—726.

The author finds that the ordinary German top-fermentation yeast is unreliable for the determination of fermentable dextrin in starch glucose syrups, since the dextrins to a very considerable extent, differ in its behaviour in this respect according to the method by which it has been prepared, e.g., whether thick mash or a clear wort. Bottom-fermentation yeast, on the other hand, at least so far as Germany concerned, is practically a standard product with all properties, since the brewer's interest lies in a fast and rapid fermentation of the free sugars with a minimum loss of dextrins. For the separation of the free sugars from the dextrins of the starch syrup, a fermentation beer yeast is regarded as the only suitable reagent; when it is desired to effect a direct determination of dextrose or invert sugar from maltose and is, a pure culture of *S. Marxiensis* should be used, if possible, four weeks being allowed for the fermentation. But since this ferment is unavailable in large quantities, approximate determinations of the maltose made by means of yeasts obtained in the manufacture of grape or berry wines. The author's results from direct and indirect determinations, indicate that free dextrin is present to the extent of about 12 per cent. in commercial potato starch glucose syrups (rich in dextrins) purified by means of acids.

Examination of "pressed" and beer yeasts on the dextrins of starch syrups.—The experiments show that there is a considerable modification, both quantitative and qualitative of the dextrins of starch syrups by the action of the yeast during the fermentation of the free sugars: these modifications are very variable, and depend apparently on the relative proportions of sugar and dextrin present, and on the concentration of the solutions. When the quantity of dextrin is large (e.g., 5—6 times that of the sugar) and the activity of the yeast is consequently high, large quantities of dextrin (e.g., 51 per cent.) are fermented simultaneously with the sugar. The residual dextrin has an unusually low rotatory power, and is practically free of aldehydic groups (cupric reducing power); the quantity of sugar is relatively small, as in an ordinary starch syrup, the quantity of dextrin lost during fermentation of the sugar is small, but since the yeast enzymes of the yeast continue to act upon the dextrin after the fermentative action has practically ceased, the residual dextrin, whilst possessing an intermediate rotatory power, contains a large proportion of aldehydic groups and may have a cupric reducing power greater than that of the dextrin present in the original

syrup, should be calculated by subtracting from the cupric reducing power of the original syrup, not the reducing power of the unfermentable dextrinous residue, but that of the dextrin isolated from the original syrup by repeated precipitations with alcohol. J. F. B.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Radio-active Minerals. Supplementary Note. R. J. Strutt. Roy. Soc. Proc., 1905, 76, A, 312.

The author has previously (this J., 1905, 693) drawn attention to the fact that all thorium minerals, so far as could be ascertained, contain uranium and radium. Analyses of a number of additional minerals, gave results in agreement with this statement. The proportions of thorium and radium in some of the minerals examined are shown in the following table:—

Mineral.	Locality.	Thorium.	Radium.
		Per cent.	Millionths of 1 per cent.
Thorite	Ceylon	61.0	1.00
Monazite	Johannesberg	5.94	1.06
Albite	Baade Moss, Norway	4.95	1.81
Monazite	Nigeria	2.98	3.78

Sulphur; Amorphous— II. *Two Liquid States of Aggregation of Sulphur, S_x and S_y, and their Transition Point.* A. Smith, W. B. Holmes and E. S. Hall. J. Amer. Chem. Soc., 1905, 27, 797—820.

It is known that if molten sulphur be chilled suddenly, a larger or smaller proportion of the solidified substance is amorphous, and insoluble in carbon bisulphide. The authors have previously (this J., 1903, 322) shown that if carbon dioxide, or, preferably, ammonia, be passed through the molten sulphur for a few minutes, then after chilling, the whole of the sulphur is crystalline, and is soluble in carbon bisulphide. Moreover, this crystalline sulphur, if used at once, may be heated to the boiling point and chilled, without any amorphous sulphur being produced. Sulphur melted immediately after recrystallisation also yields no amorphous sulphur. Treatment of the crystalline sulphur with sulphur dioxide restores its capacity of yielding amorphous sulphur. Further experiments have now shown that there are two liquid states of sulphur which are partially miscible, the yellow mobile liquid, S_x, which predominates from the m.p. (115° C.) up to 160° C., and the brown viscous liquid, S_y, which prevails above 160° C. As the temperature rises, the saturation of S_x with S_y determines the separation of the new phase, whilst, when the temperature falls, the converse is the case. The absorption of heat connected with the transition from one form to the other, occurs at 162.5° C. and upwards, and the liquid becomes viscous at the same moment. The temperature falls to 162° C., and the transition point is therefore not higher than this temperature. These phenomena take place in the same way, and at the same temperature, whether the sulphur is such as by chilling gives insoluble sulphur, or, having been treated with ammonia, does not. The two modifications have different solubilities in triphenylmethane and other solvents: that of S_x increases, whilst that of S_y decreases with rise of temperature. On dissolving, for instance, 18 grms. of sulphur in 10 grms. of triphenylmethane, and cooling the hot solution, liquid sulphur separates at 147° C.; on again raising the temperature, the emulsion first becomes clear, and then at 214.5° C., liquid sulphur again separates.—A. S.

The author concludes, therefore, that the cupric reducing

Clay as a Semi-permeable Diaphragm Material. P. Rohland. Z. Elektrochem., 1905, 11, 455-456.

NEITHER crystalline kaolin nor poor clay possesses the property known as *semipermeability*, this being peculiar to the rich plastic clays. This property is, however, only apparent after the clay has been air-dried in the wet state in which it is dug from the earth; it is impossible even for water to pass through it. The rich plastic clays, in their natural state, are characterised by a high loss of weight on ignition, this being due partly to their water contents, and partly to organic compounds. A typical clay gave the following figures:

Loss on ignition 13.4 per cent. SiO_2 52.5 per cent. Al_2O_3 29.0 per cent. Fe_2O_3 3.4 per cent. CaO 1.0 per cent. MgO 0.02, alkalis, 1.0 per cent.

Such a clay will allow crystalline substances in solution, such as sodium and barium chlorides, copper sulphate, and potassium bichromate, to pass through it, whilst colloids, like ferric hydroxide, silicic acid, starch solution, and iron saccharate, will be held back. The action of this clay when used as a diaphragm in solutions of carbonates, is peculiar. With sodium carbonate, the clay acts as a non-permeable material; the anion being held back, while the cation enters the diaphragm and displaces the lime in its chemical combination. The clay diaphragm in this case, thus brings about a chemical change in the diffusion liquid. As explanation of this property of the rich plastic clays, the author states that they contain colloidal constituents partly of organic and partly of inorganic origin, and that it is a law that colloids subject to coagulation, cannot take up or allow to pass through them, colloidal substances in solution; while they will allow crystalline substances and water, to diffuse quickly.

As regards the speed application and value of these rich plastic clays, the author states that they may be of considerable importance in connection with plant nourishment—by means of soluble crystalline bodies—since the clays may assist the plant in conjunction with osmotic pressure in obtaining a supply of these bodies from the soil.—J. Trade Report.

I.—GENERAL.

GERMANY; TRADE OF —.

For. Off. Ann. Series, No. 3445.

The following table shows the value of certain imports and exports for the year 1904, as compared with those of the years 1902-03:—

Articles.	Value in 1000 Marks (50 <i>l.</i>).					
	Imports.			Exports.		
	1904.	1903.	1902.	1904.	1903.	1902.
Lead and leaden goods	15,571	13,331	9,085	16,357	17,800	14,311
Drugs and dyes	291,350	274,376	263,392	416,685	393,975	380,000
Iron and iron goods	62,892	56,310	51,828	606,338	634,361	603,600
Ores, fine metals, asbestos, &c.	745,049	533,076	355,661	165,108	189,775	206,000
Glass and glassware	9,994	9,255	8,699	55,037	51,450	48,000
Hides	334,822	329,838	258,995	161,217	148,966	137,000
Caoutchouc, gutta-percha, and goods thereof ..	101,966	93,605	73,263	63,665	62,888	50,000
Copper and copper goods	171,028	132,242	109,011	168,009	156,437	120,000
Leather and leather goods	66,893	69,433	64,378	176,705	172,766	153,000
Candies	247	187	194	740	864	864
Oils, not otherwise mentioned, and fats	244,829	228,926	261,102	52,724	46,916	47,000
Paper and cardboard goods	24,755	18,067	15,207	134,083	121,903	109,000
Petroleum	100,372	110,581	93,109	2,138	1,726	1,000
Soap and perfumery	2,954	2,810	2,706	13,965	14,104	17,000
Stones and earthenware	45,719	43,708	45,154	35,764	37,981	38,000
Coal, brown coal, coke, and peat	170,070	162,274	163,231	297,916	287,983	267,000
Tar, pitch, resin and asphaltum	44,228	45,343	31,834	13,841	13,516	10,000
Oilcloth	860	925	863	3,200	3,120	2,000
Zinc and zinc goods	11,457	11,191	9,870	46,307	42,454	39,000
Tin and tinware	37,475	36,270	34,952	14,270	12,664	13,000

Some classes of chemical products exports have declined, partly owing to an unfavourable development. Thus the value of quinine alkaloids was, in 1904, 3,300,000 marks; in 1903 7,000,000 marks. The value of tar colours maintained its position; the export of tar colours, Alizarin, artificial indigo and caustic potash has considerably increased.

Imports of the following articles has also increased:—

II.—FUEL, GAS, AND LIGHT.

COAL BRIQUETTES IN JAPAN.

Eng. and Mining J., July 15, 1905.

A plant for the manufacture of briquettes in Japan has been started at Tokuyama, and commenced operations on July 14, under the ownership and control of the Japanese Government, which also owns the Omine mine, from which coal is taken for the manufacture of the briquettes. To convey the coal to the factory a railway has been built, 10 miles in length, connecting the mine with the line of the Sanyo railway system. The capacity of the factory under normal conditions is said to be about 100,000 tons per annum, its full capacity being, however, 120,000 tons. The estimated cost of the briquettes is 10 shillings per ton. The total expense incurred in starting

present there are 11 manufacturing works of producing 40,000 tons of calcium carbide annually. The demand is far from corresponding to the amount of production, and the total output sold during 1904 may be closely estimated at 18,000 tons.

The average yield of gas is 300 litres per kilo. of carbide. The French manufacturers are completely protected against importations by the Bullier patent, and manufacturers of carbide and of acetylene have reached an understanding whereby an average price has been established which enables both industries to exist. The production of 1904 was disposed of at 200 francs per ton, the standard accepted and declared being 300 litres of gas per kilogram. The retail price is 350 francs per ton.

III.—TAR PRODUCTS, PETROLEUM, Etc.

PETROLEUM PRODUCTION OF THE UNITED STATES IN 1904.

Bl. of Trade J., July 20, 1905.

According to statistics collected by the United States Geological Survey, the production of crude petroleum in the United States last year amounted to 117,963,421 barrels valued at 101,170,466 dol., as compared with 100,461,337 barrels valued at 94,694,050 dol. in 1903. The average value of the oil per barrel fell from 0.94 dol. in 1903 to 0.86 dol. in 1904, a decrease of 8 cents a barrel.

VII.—ACIDS, ALKALIS, Etc.

NITRATE OF SODA STATISTICS.

W. Montgomery and Co., June 30, 1905

Shipments, Consumption, Stocks and Prices, from 1903 to 1905.

	1903.	1904.	1905.
Imports from South American ports to all parts for the six months ending 30th June	Tons 550,000	578,000	685,000
do. for the twelve months ending 30th June	1,315,000	1,463,000	1,583,000
for Europe on 30th June	227,000	199,000	226,000
in U.K. ports:—			
	1903.	1904.	1905.
Liverpool	Tons 2,000	5,500	4,500
London	1,600	800	1,800
Other ports	2,500	4,400	4,900
Stocks in Continental Ports on 30th June	Tons 31,000	21,000	26,800
Imports in U.K. for the six months ending 30th June	77,000	78,000	67,000
Do. in Continent do.	754,000	749,000	820,000

Do. in the World do.	1,380,000	1,441,000	1,513,000
Supply on 30th June (including the quantity abroad for Europe and stocks in U.K. and Continent)	258,000	231,000	274,000
on 30th June	per Cwt. 9 1/2	9 1/4	11 1/2

The plant was about £100,000. The machinery was raised in England. The output of the factory of the Nippon Kaisha, which manufactures briquettes at Nagasaki, was 50,000 tons in 1904. The capacity of the plant has been increased from 70,000 to 120,000 tons per annum, and the Japanese Admiralty continues to take the output at 10 shillings per ton.

CALCIUM CARBIDE INDUSTRY OF FRANCE.

U.S. Cons. Rep. No. 2310, July 17, 1905.

The principal centres of the calcium carbide industry in France are in the Alps and the Pyrenees, particularly in the towns of Bellargue, Grenoble, Nice, and Toulouse. At

X.—METALLURGY.

MINES AND QUARRIES: GENERAL REPORT FOR 1903: PART IV.

Colonial and Foreign Statistics. [Cd. 2,600.] Price 1s. 9d.

The report contains statistics relating to persons employed, output, and accidents at mines and quarries in the British Empire and in foreign countries, each country and possession being treated separately.

From the summary of output for 1903 the following table has been compiled:—

	British Isles	British Empire, excluding British Isles	Foreign Countries.
	Met. tons	Met. tons	Met. tons
Coal	231,030,784	26,584,114	620,388,038
Copper	745	61,320	548,120
Iron	4,576,202	529,555	39,416,205
Lead	29,278	119,741	722,880
Petroleum	—	416,000	25,816,009
Salt	1,917,274	1,076,537	9,824,442
Tin	4,751	56,621	37,323
Zinc	9,430	15,558	545,452
	Kilos	Kilos	Kilos
Fine Gold	154	281,684	266,835
Fine Silver	3,440	499,432	4,492,619

IRON AND STEEL PRODUCTION OF CANADA, IN 1904.

Bd. of Trade J., July 13, 1905.

The "Bulletin" of the American Iron and Steel Association publishes statistics, received direct from the manufacturers, of the production of steel ingots and castings and of all finished rolled iron and steel in Canada in 1904, from which the following table is compiled:—

	1903.	1904
	Tons of 2,240 lbs.	Tons of 2,240 lbs.
Steel ingots and castings	181,514	148,784
Bessemer and open-hearth steel rails	1,243	36,216
Structural shapes	1,983	447
Cut nails*	118,686 Kegs.	99,000 Kegs.
Plates and sheets	2,456 Tons	3,102 Tons
All other finished rolled products	118,541	135,243
All kinds of iron and steel rolled into finished forms	129,516	180,078

* Made by rolling mills and steel works having cut-nail factories connected with their plants.

The production of iron ore in Canada in 1904 amounted to 312,286 tons, against 235,977 tons in 1903, and the production of coal to 6,705,232 tons, against 6,824,999 tons in 1903.

MINING IN NORWAY.

For. Off. Ann. Series, No. 3425.

In the Sulitjelma copper mines about 1,400 men were employed in 1904. From about 20,000 tons turned out in 1894, the quantity produced by these works has risen from year to year until it reached about 80,000 tons in 1904. Of this amount about 64,000 tons of copper pyrites, containing 45 per cent. sulphur and 3½ to 4½ per cent. copper were exported, and also about 15,000 tons of ore for smelting. 11,350 tons of pyrites went to Norwegian sulphite works. An output of 100,000 tons is projected for the current year, 85,000 tons of pyrites for export, and 15,000 tons of smelting ore. The Alten Copper Works in Finnmarken and the Krængen mine have employed about 360 men; copper ore has been produced containing 390 tons of copper. The Bossmo pyrites mine in Møi Rauen produced 26,100 tons of pyrites containing 49·5 or 50 per cent. of sulphur, and employed about 240 men. The Røros Copper Works produced about 18,000 tons smelting ore and 11,000 tons pyrites: 733 tons of copper were sold during the year. The Killingdal mine, north of Røros, produced 14,000 tons pyrites and employed about 100 men. The prospects of this mine have been improved by the discovery of a continuation of the main lode. The mining of iron pyrites, principally for export, has increased from 105,000 tons in 1900 to about 120,000 tons in 1904.

Italian sulphur, which has hitherto been used in Norwegian sulphite-cellulose factories, is now being replaced by Norwegian pyrites: 12,000 or 13,000 tons of sulphur were formerly imported, but the factories build roasting ovens for Norwegian fine pyrites, thus saving about 5 kr. per ton of cellulose. When factories have carried out this plan, the home consumption of pyrites is estimated to rise to 30,000 tons per year compared with 15,000 tons in 1904. The production of pyrites in 1905 is expected to rise to about 160,000 tons on account of the extended workings at Sulitjelma and Kjöll.

Between 3,000 and 3,100 men were employed in the Norwegian copper ore mines, and the gross value of the products, delivered at a Norwegian port, amounted to about 264,000 kr., which is over 26 per cent. more than the average for the five years ending in 1900.

The Evje Nickel Works, which are the only works have been used of late, produced 5,352 tons of nickel in 1904: 4,819 tons of ore and regulus ("grus") were smelted. The exports were 166 tons of stone and 4 tons of copper stone, containing 72 tons of nickel and 43 tons of copper; the prospects of the mine are very good. It has been discovered during the year that the comparatively high percentage of nickel in the ore from this mine is due to the presence of even microscopic, iron nickel pyrites containing 33 per cent. of nickel.

39,000 tons of iron ore (about the same quantity) was exported from the Fehn mines near Nordsjø, where about 230 men were employed. The total export of iron ore from Norway in 1904 amounted to about 45,000 tons, compared with 41,570 tons in 1903.

From Narvik 1,188,500 tons of Swedish iron ore from Kiruna were exported. 760,900 tons of this ore went to Germany and 286,500 tons to the United Kingdom.

Without taking apatite, feldspar, &c., into consideration, about 3,900 workmen were employed in the past year in Norwegian mines, and the gross value of the products (those exported being calculated as delivered at a Norwegian port) is estimated at about 3,000,000 kr. The mining industry is increasing on account of the development of Northern Norway. If apatite, feldspar, granite, labradorite, roofing slates and cement are included, the gross value of the products of stone and minerals is estimated at 585,000 kr. for the past year, which shows an increase on former years. About 1,570,000 kr. of mining products were shipped from Norwegian ports in 1904, of which nearly 1,200,000 tons were transited via Narvik: the balance, about 370,000 tons, came from Norwegian sources.

XII.—FATS, FATTY OILS, Etc.

COTTON-SEED OIL; AUSTRALIAN "METHYLATION"
Bd. of Trade J., July 27, 1905.

The "Commonwealth of Australia Gazette" of May last, contains the following Customs by-law which came into force on 8th May, 1905, regulating the "methylation" of cotton-seed oil within the Commonwealth:

1. Imported cotton-seed oil, or cotton-seed oil factured from imported cotton-seed, delivered in accordance with departmental by-laws, may be methylated in pursuance of these by-laws.

2. Prior to removal from the wharf, if imported, or from the place of manufacture, if not imported, the oil shall be sealed by an officer.

3. After the oil has been sealed it shall only be removed by the authority and in the presence of an officer.

4. Immediately after the oil has been opened, it shall be methylated in the presence and to the satisfaction of an officer.

5. In this by-law "methylated" means mixed with a substance approved by the Collector, in such a manner as to render the oil unfit for use as a beverage, or for any other purpose, or incapable of being converted to that use.

The above By-law repeals the By-laws of 3rd December 1901, and 3rd April 1903.

OLIVE OIL PRODUCTION OF LECCE.

For. Off. Ann. Series, No. 3427.

The olive crop of the province of Lecce suffered much the ravages of the *Mosca oleacea*, the 1904 crop being reduced to be only one-tenth of a normal crop. The prospects for 1905 are not promising. The exports of oil from the province amounted to 12,347 tons, of which 10,600 tons was sent to other Italian ports (including Sicily and Sardinia); the oil export of 1903 amounted to 12,347 tons, and in 1902 to 9,594 tons, of which quantities, 10,600 tons and 7,468 tons respectively were shipped to foreign ports.

XIII. C.—INDIA-RUBBER, Etc.

INDIA-RUBBER TRADE OF PARÁ.

For. Off. Ann. Series, No. 3436.

The director of the local botanic gardens reports in the Bulletin of the Pará Museum, that it has been recently ascertained that a latex obtained from a tree entirely different from the "Hoveas" has been employed not only to produce rubber, but even in some cases to replace gutta-percha. The substitute is said to be slightly less elastic than the genuine article. It seems that the demand has led to the practice for some years past, and is in question are plentiful and exist over a very large area, and are known in the State of Amazonas by the name of "Tapurú," and in the neighbourhood of Manaus as "Murupita," "Seringa-Rana," &c. Botanists are of opinion that these trees belong to a species of *Hevea*. The advantages of the "Tapurú" and its substitutes consist in their being more plentiful than the gutta-percha, and in their more rapid reproduction. The output of Amazonian rubber from July, 1903—July, 1904, amounted to 30,533 tons, valued at 11,000,000*l.*; quantity 11,362 tons, value 2,807,741*l.*, was exported to the United Kingdom, compared with 11,327 tons, valued at 3,059,000*l.* in the previous year. The export of rubber of all kinds from Pará during 1903 amounted to 10,000 tons, as against 27,100 tons in 1902; of these quantities, 12,228 tons (1903) and 11,794 tons (1902) were exported to the United Kingdom.

XIV.—TANNING; LEATHER; GLUE, Etc.

QUEBRACHO EXPORTS FROM ARGENTINA.

For. Off. Ann. Series, No. 3434.

The export of quebracho extract from Argentina amounted in 1904 to 20,111 tons in 1904. It goes mostly to the United States. The export of quebracho sleepers decreased from 374 to 6301 sleepers. It is likely to be almost nil in 1905 as the price has gone up in the past year by quite 50 per cent, and the supply is for the moment not equal to demand; the railway companies are also applying to the Government for permission to use other wood or sleepers instead. The durability of red quebracho sleepers is unrivalled, no creosoting being required. The export of quebracho logs in 1904 increased by 10 per cent to 252,723 tons. Most of these are used for tanning hides, the quebracho from the eastern part of the country being far the best for this purpose. The best red quebracho for sleepers comes from the province of Santiago del Estero.

Patent List.

N.B.—In these lists, A. means "Accepted," and C.S. means "Complete Specification Accepted."

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (a) in the case of Applications for Patents, the dates of application, and (b) in the case of Complete Specifications Accepted, those of the Official Journal in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition, within two months of said date.

I.—PLANT, APPARATUS, AND MACHINERY.

- [A.] 14,700. Gasquet. Apparatus for washing and cleaning casks, vats, carboys, &c. July 17.

II.—FUEL, GAS, AND LIGHT.

- [A.] 14,687. Langhans. Manufacture of incandescing media for lighting purposes.* July 17.
- .. 14,783. Otto-Hilgenstock Coke Oven Co. (Otto and Co.). The coking of coal and similar substances in coke ovens. July 18.
- .. 14,898. Crawford. Manufacture of filaments for incandescing electric lamps. July 19.

- [A.] 14,972. Brit. Thomson-Houston Co. (Gen. Electric Co.). Process of obtaining a substance particularly adaptable for making incandescent electric filaments thereof. July 20.
- .. 15,194. Tully. Manufacture of gas suitable for heating and illuminating purposes. July 24.
- .. 15,226. Parry and Pillinger. Manufacture of coal gas and furnaces therefor. July 25.
- .. 15,507. Koppers. Process for the separation of carbon from hydro-carbons.* July 28.
- .. 15,576. Hiby. Coke ovens. July 28.
- [C.S.] 11,971A (1904). Clay and Goodall. Production of combustible fluids for power purposes. Aug. 2.
- .. 16,008 (1904). Koppers. Gas delivery and purifying apparatus for coke ovens and gas generating plant. July 26.
- .. 16,069 (1904). Smith. Manufacture of producer gas applicable both to pressure and suction plants. July 26.
- .. 1587 (1905). Marconnet. Producing gas from pulverulent fuel. Aug. 2.
- .. 4291 (1905). Knops. Manufacture of artificial fuel. July 26.

III.—DESTRUCTIVE DISTILLATION. TAR PRODUCTS. PETROLEUM, AND] MINERAL WAXES.

- [C.S.] 16,756 (1904). Lyndall and Costley-White. Process for rendering benzine or the like non-inflammable. Aug. 2.

IV.—COLOURING MATTERS AND DYESTUFFS.

- [A.] 14,787. Ransford. (Cassella and Co.). Manufacture of trisazo dyestuffs. July 18.
- .. 15,170. Abel (Act.-Ges. f. Anilinfabr.). *See under XIII.A.*
- .. 15,295. Imray (Meister, Lucius und Brüning). Manufacture of *o*-oxymonoazo dyestuffs. July 25.
- [C.S.] 25,901 (1904). Imray (Soc. Chem. Ind. in Basle). Manufacture of brown monoazo dyestuffs developed by chroming. July 26.
- .. 1817 (1905). Johnson (Badische Anilin und Soda Fabrik). Manufacture of new compounds of the anthracene series. July 26.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

- [A.] 14,849. Rheinische Webstuhl- und Appretur-Maschinenfabr. Process of dyeing textile fabrics and the like in graduated depths of shade or tone. [Ger. Appl., Jan. 6, 1905.]* July 19.
- .. 14,866. Asher. Method of dyeing sponges.* July 19.
- .. 15,029. Dietl. Manufacture of artificial silk.* July 21.
- .. 15,233. Wilkinson. Apparatus for gassing or cleansing silk and other threads. July 25.
- .. 15,372. Douge. Apparatus for regaining the solvents of nitrocellulose in the manufacture of artificial silk. [Fr. Appl., April 21, 1905.]* July 26.
- .. 15,444. Haigh and Wheeler. Means of rendering certain substances and materials non-inflammable and waterproof. July 27.
- .. 15,518. Pomortzeff. Treatment of all kinds of woven fabrics and paper for increasing their durability and rendering them waterproof. July 28.

- [A.] 15,524. Johnson (Badische Anilin und Soda Fabrik). Discharging dyed materials and to be employed therein. July 28.
- .. 15,532. Venter. Apparatus for dyeing, more or bleaching loose materials, spun tops, knitted goods, and the like.* July 28.
- [C.S.] 16,503 (1904). Wild. Dyeing textile fabrics. Aug. 2.
- .. 20,665 (1904). Kenworthy and Ward. Per beams or cylinders on which textile fabrics materials are treated with liquids. Aug. 2.
- .. 21,509 (1904). Mather and Platt, Ltd., and Roller printing machines for fabrics. Aug. 2.
- .. 1686 (1905). Vittenet. Manufacture of silk. Aug. 2.
- .. 4947 (1905). Kübler. Method and apparatus producing mottled colouring effects in silk. July 26.
- .. 4971 (1905). Walker. Compounds and process for fireproofing textile fabrics and threads. July 21.
- .. 5244 (1905). Fletcher. Dyeing machines. Aug. 2.

VII.—ACIDS, ALKALIS, AND SALTS.

- [A.] 15,308. Lake (Rowley). Manufacture of hydroxide of lead and apparatus for use with. July 25.
- .. 15,353. Monson. *See under XV.*
- [C.S.] 16,353 (1904). Shields. Treatment of the issuing from pyrites burners. Aug. 2.
- .. 20,012 (1904). Davis and Davis. Plant for manufacture of sulphuric acid. Aug. 2.
- .. 4245 (1905). Schmatolla. Kilns for burning stone, dolomite and the like. July 26.
- .. 7032 (1905). Cie. des Prod. Chim. d'Alain Camargue. Calcination of hydrated salts. Aug. 2.
- .. 11,180 (1905). Wetter (J. D. Riedel, A.G.). Salts of mercury. Aug. 2.

VIII.—GLASS, POTTERY, AND ENAMELS.

- [A.] 15,440. Jones. Ornamentation or decoration of pottery ware. July 27.
- .. 15,452. Bundy. Process for producing effects on glass, porcelain and like materials. July 27.
- [C.S.] 9211 (1905). Sievert. Manufacture of sheet glass. Aug. 2.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

- [A.] 14,709. Walden. Asphaltic cement. July 17.
- .. 14,970. Hannay. Treatment of timber. July 20.
- .. 15,325. Rosenbaum. Compositions relating to the manufacture of artificial marble. July 23.
- [C.S.] 19,385 (1904). Bower. Manufacture of substances for lithographic stones. Aug. 2.
- .. 6391 (1905). Clarke. Grinding apparatus for manufacturing cement. Aug. 2.
- .. 9766 (1905). Toyn. Jointing cements, coverings or like compositions. Aug. 2.

X.—METALLURGY.

- [A.] 14,688. Kingsley and Mally. Process and apparatus for treating sulphide and other ores. July 17.
- .. 14,733. Wilkins. New alloy. July 18.

15,055. Ganz and Co. *See under XI.*

15,123. Richardson. Smelting and refining *ores*. July 22.

15,367. King. Methods of purifying and nodulizing metalliferous materials. [U.S. Appl., Nov. 14, 1904.]* July 26.

15,375. Timm. Process for dissolving solid fluxes in fluid slag. [Ger. Appl., July 29, 1904.]* July 26.

15,423. Churchward. Hardening and toughening metals.* July 27.

8677 (1904). Hyatt. Gold extraction. July 26.

13,578 (1904). Elmore. Separating certain constituents of subdivided ores, &c., and apparatus therefor. July 26.

15,793 (1904). Buss. Apparatus for concentrating and separating ores. July 26.

19,464 (1904). Reinke. Process for briquetting friable ores and ore waste. Aug. 2.

19,653 (1904). Ellis and Highton. Apparatus for extracting gold from slimes, tailings or the like. Aug. 2.

20,300 (1904). Ogle, Sulman and Picard. Treatment of ore slimes and the like. Aug. 2.

961 (1905). Dekker. Treatment of metallic compounds of sulphur, arsenic and antimony. July 26.

11,073 (1905). Casman. Process of extracting and refining the copper and alloys of copper contained in ashes, sand, and waste from foundries and other works. July 26.

X.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

14,955. Johnson (Badische Anilin und Soda Fabrik). Production of long stable electric arcs. July 20.

15,055. Ganz and Co., Eisengiesserei und Maschinenfabrik Akt.-Ges. Process for extracting metals from ores and other metalliferous material by electrolytic means, and apparatus therefor. [Ger. Appl., Aug. 26, 1904.]* July 21.

15,257. Gardiner and Stringfield. Storage batteries.* July 25.

15,458. Burn-Murdoch and the Sherardizing Syndicate, Ltd. Deposition of metals or compounds. July 27.

18,042 (1904). Imray (Meister, Lucius und Brüning). Oxidation and reduction in an electrolytic bath. July 26.

18,356 (1904). Bartelt. Electrolysers. Aug. 2.

20,809 (1904). Brit. Thomson-Houston Co. (Gen. Electric Co.). Electric furnaces. Aug. 2.

20,810 (1904). Brit. Thomson-Houston Co. (Gen. Electric Co.). Electric furnaces. Aug. 2.

6650 (1905). Schenk. Galvanic cells. Aug. 2.

12,291 (1905). Classen. Electrolytic production of lustrous metallic coatings upon metals. July 26.

X.—FATTY OILS, FATS, WAXES, AND SOAP.

15,023. Balthasser-Weygang. *See under XVIII.A.*

15,231. Ridgill. Apparatus and method of extracting oil and fatty matters from substances containing them. July 25.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES, INDIA-RUBBER, Etc.

(A).—PIGMENTS; PAINTS.

[A.] 15,088. Carroll. Paint. July 22.

" 15,170. Abel (Act.-Ges. f. Anilinfabrik). Manufacture of new colour lakes and of dyes therefor. July 24.

" 15,398. Bennett and Martin. Manufacture of pigments.* July 27.

" 15,582. Hoffmeister, Hundt, Eder and Wundt. New paint or composition. July 29.

(B).—RESINS, VARNISHES.

[C.S.] 12,460 (1905). Wachendorf. Manufacture of varnishes for producing matt surfaces. July 26.

(C).—INDIA-RUBBER.

[A.] 14,681. Alexander. Production of aqueous colloidal caoutchouc solutions and the regeneration of caoutchouc waste.* July 17.

XIV.—TANNING, LEATHER, GLUE, SIZE, Etc.

[C.S.] 18,267 (1904). Baily. Treatment or preserving of skins. July 26.

XV.—MANURES, Etc.

[A.] 15,353. Monson. Process for rendering natural phosphates readily assimilable by plants. July 26.

[C.S.] 15,709 (1904). Bentan. Manufacture of manure. July 26.

XVI.—SUGAR, STARCH, GUM, Etc.

[A.] 14,662. Vincent and Gengnagel (Witty). *See under XVIII.A.*

" 15,023. Balthasser-Weygang. *See under XVIII.A.*

" 15,403. Williams. Glaze starch. July 27.

[C.S.] 20,166 (1904). Gonville and Jarvis. Caramelisation of carbohydrates. July 26.

XVII.—BREWING, WINES, SPIRITS, Etc.

[A.] 14,678. Suden and the Berliner Act.-Ges. f. Eisengiesserei und Maschinenfabrik. The malting of grain. July 17.

" 14,679. Suden and the Berliner Act.-Ges. f. Eisengiesserei und Maschinenfabrik. Malting apparatus. July 17.

" 15,250. Schneible. The art of brewing. [U.S. Appl., Aug. 1, 1904.]* July 25.

XVIII.—FOODS; SANITATION, WATER PURIFICATION; & DISINFECTANTS.

(A).—FOODS.

[A.] 14,662. Vincent and Gengnagel (Witty). Production of saccharine cattle food from molasses and sugar syrups. July 17.

" 15,023. Balthasser-Weygang. Process for producing foodstuffs, glycerine and saccharine like substances and other products. July 21.

" 15,304. Budde. Sterilisation of articles of food. July 25.

- [A.] 15,311. Mann. Manufacture of butter substitutes. [Ger. Appl., Nov. 30, 1904.]* July 25.
 .. 15,391. Wuthrich. Method of condensing milk in a vacuum.* July 26.
 [C.S.] 17,818 (1904). Bonna and Selhorst. Production of milk free from sugar. July 26.
 .. 20,339 (1904). Hatmaker. Milk food. Aug. 2.
 .. 20,340 (1904). Hatmaker. Milk food. Aug. 2.
 .. 20,793 (1904). Van Gulpen. Process and apparatus for making coffee extracts. Aug. 2.
 .. 3284 (1905). White. Manufacture of coffee essence. July 26.

(B).—SANITATION: WATER PURIFICATION.

- [C.S.] 16,689 (1904). Tuckfield and Garland. Regenerative heating apparatus for use in the purification of water and sewage and for like purposes. Aug. 2.

XIX.—PAPER, PASTEBOARD, Etc.

- [A.] 14,789. Dobler. Sizing paper or card.* July 18.
 .. 15,417. Lockett and Baker. Method of and means for applying size to paper during manufacture. July 27.
 .. 15,518. Pomortzeff. *See under V.*
 [C.S.] 19,178 (1904). Beadle and Stevens. Manufacture of blotting and other waterleaf papers. Aug. 2.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

- [A.] 15,118. Nicolaidi. Manufacture of an official preparation of phosphoric acid. July 22.
 .. 15,456. Zimmermann (Chem. Fabr. auf Actien, vorm. E. Schering). Manufacture of benzoyl-alkylaminoethanols. July 27.

- [A.] 15,375. Imray (Meister, Lucius und B) Manufacture of Δ^4 -cyclogeranic aci ing and derivatives thereof. July 28.
 .. 15,517. Fabr. Prod. Chim. Organique d' Manufacture of products of condensa n of phenol alcohols. [Fr. Appl., Sept. 16, 04.]* July 28.
 [C.S.] 24,990 (1904). Imray (Meister, Lucius und B) Manufacture of alkylbarbituric acids. ing and
 .. 713 (1905). Anderson. Medicinal prep tion.
 .. 1503 (1905). Lake (California Product Co.,) Process of producing cream of tartar. g. 2.
 .. 10,201 (1905). Chem. Fabr. von Heyden & Manufacture of guanildialkylbarbituri acid.
 Aug. 2.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

- [A.] 15,185. Brasseur. Multicolour photog
 July 24.
 .. 15,214. Gillard and Molyneux. Manufa
 emulsions and other materials sensitive li
 July 25.

XXII.—EXPLOSIVES, MATCHES, Etc.

- [A.] 14,958. Deutsche Sprengstoff Act.-Ges. Manufacture of nitroglycerine explosives [Ger. Appl., Dec. 10, 1904.]* July 20.
 .. 15,564. Cocking, and Kynoch, Ltd. St
 powders. July 29.
 .. 15,565. Cocking, and Kynoch, Ltd. St
 powders. July 29.
 .. 15,566. Cocking, and Kynoch, Ltd. St
 powders. July 29.

XXIII.—GENERAL ANALYTICAL CHEMISTRY.

- [A.] 15,160. König. Titration apparatus.* July 24.

JOURNAL OF THE Society of Chemical Industry.

A RECORD
FOR ALL INTERESTED IN CHEMICAL AND ALLIED MANUFACTURES.
ISSUED TWICE A MONTH.

16.—Vol. XXIV.

AUGUST 31, 1905.

No. 16.—Vol. XXIV.

Subscription of Members 25 - per annum;
Entrance Fee 21/-;
Election by the Council.

Price to Non-Members 36 - per annum;
To Members 25 - per Set of extra or back numbers.
Single copies (Members and Subscribers only)
1882—1901, 2 6 each: 1902 *et seq.*, 1 9 each.

Society of Chemical Industry.

Past Presidents:

Henry E. Roscoe, B.A., D.C.L., LL.D., F.R.S.	1881—1882.
Frederick A. Abel, Bart., K.C.B., C.V.O., D.C.L., D.Sc., F.R.S.	1882—1883.
Arthur Weldon, F.R.S.	1883—1884.
A. Perkin, LL.D., Ph.D., F.R.S.	1884—1885.
C. Muspratt	1885—1886.
Edmund Howard	1886—1887.
James Dewar, M.A., LL.D., F.R.S.	1887—1888.
Ludwig Mond, Ph.D., F.R.S.	1888—1889.
Lowthian Bell, Bart., F.R.S.	1889—1890.
Richard Cook	1890—1891.
Emerson Reynolds, M.D., F.R.S.	1891—1892.
John Evans, K.C.B., D.C.L., LL.D., F.R.S.	1892—1893.
C. C. Stanford	1893—1894.
John Thorpe, C.B., LL.D., Sc.D., Ph.D., F.R.S.	1894—1895.
Thomas Tyrer	1895—1896.
Richard Schunck, Ph.D., F.R.S.	1896—1897.
John Clowes, D.Sc.	1897—1898.
George Beilby	1898—1899.
Chandler, D.Sc., M.D., Ph.D., LL.D.	1899—1900.
Thomas W. Swan, D.Sc., M.A., F.R.S.	1900—1901.
Ivan Levinstein	1901—1903.
Ramsay, K.C.B., D.Sc., LL.D., F.R.S.	1903—1904.
H. Nichols, M.S., LL.D., D.Sc.	1904—1905.

† Deceased.

LIST OF COUNCIL, 1905—1906.

President: Dr. Edw. Divers, F.R.S.

Vice-Presidents:

Leckland.	Dr. J. Lewkowitsch.
Bell.	N. H. Martin.
Cublenitz.	Max Muspratt.
R. E. Hodgkinson.	Dr. Wm. H. Nichols.
Howard.	T. J. Parker.
Levinstein.	Sir Wm. Ramsay, K.C.B., F.R.S.

Ordinary Members of Council:

Dunn.	Dr. K. E. Markel.
Stmann.	B. E. R. Newlands.
Gray.	Prof. W. J. Pope, F.R.S.
R. Lang.	Sir Boverton Redwood.
W. G.	Walter F. Reid.
Arthur.	Dr. W. S. Squire.

Sectional Chairmen and Secretaries:

BIRMINGHAM.	
F. Frankland, F.R.S.	F. R. O'Shaughnessy.
CANADIAN.	
Smalls.	Alfred Burton.
LIVERPOOL.	
Gray.	W. Roscoe Hardwick.
LONDON.	
Salomaa.	Julian L. Baker.

Official Notices.

COMMUNICATIONS.

Members of communications read before the Society, or its Local Sections, are requested to take notice that Rule 43 of the Bye-laws the Society has the right of publication for three months of all such papers. Payment of this Bye-law renders papers liable to be used for the Journal, in which case no reprints can be sent to the author.

INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY, ROME, 1906.

Sixth International Congress of Applied Chemistry held in Rome in April, 1906, during Easter week. Communications should be addressed to the Secretariat, Prof. E. Paternò, Via Panisperna, 89 Rome.

Changes of Address.

In notifying new addresses, members are requested to state distinctly, and state whether they are temporary or permanent. Multiplication of addresses is to be avoided as tending to create confusion. When giving subscriptions, the use of the form attached to the Journal helps in the verification of addresses, on the safe delivery of the Journal depends.

Annual General Meeting.

(Continued.)

MONDAY, JULY 17TH.

On Monday morning the American and Canadian visitors accompanied by a number of home members, about 70 in all, started on their tour of the British Sections. At Nottingham, their first stopping place, they were received by Mr. J. T. Wood (Chairman of the Section), Mr. S. F. Burford (Vice-Chairman), Mr. S. R. Trotman (Hon. Local Secretary) and other members of Committee. Here a party was detached for Burton-on-Trent, while the remainder lunched at the Victoria Station Hotel, Nottingham.

One Burton party was conducted over Messrs. Bass' Brewery, where they were entertained at luncheon by the firm, Mr. C. O'Sullivan, F.R.S., in the chair. The toasts, proposed by Dr. H. W. Wiley and Prof. C. F. Chandler, were drunk in "King's Ale." This brew of 400 barrels, which King Edward started in February, 1902, contains 14 per cent. alcohol, and will reach maturity in about 40 years. The visitors were then shown the various stages of brewing, stress being laid on the chemical side and precautions for preventing impure fermentations pointed out.

Another party visited Messrs. Allsopp's Brewery and was received by the Chairman of the Company, Mr. C. J. Stewart, and the General Manager, Mr. H. Mead-Taylor. After luncheon at the Brewery, the party was conducted through the works by Mr. John Hutton, one of the Assistant Brewers. Particular interest centred in the firm's recent development as brewers of a light lager beer. Allsopp's lager beer shows pretty much the same composition as the light beers brewed in Germany and elsewhere. It is stated to contain alcohol, by weight 3.41 per cent., by volume 4.28 per cent., extractives, 4.45 per cent.; mineral matter, 0.17 per cent.; sugar, 0.74 per cent.; and volatile acidity calculated to acetic acid, 0.078 per cent. The stout contains alcohol, by weight 6.71 per cent., by volume 8.36 per cent., extractives,

6.67 per cent.; mineral matter, 0.33 per cent.; sugar, 0.357 per cent.; proteid, 0.52 per cent.; and volatile acidity calculated as acetic acid, 0.024 per cent. Samples of the lager beer, the stouts and strong ales were put before the party and greatly appreciated.

A third party was conducted over the lace making and finishing manufactory of Messrs. Thos. Adams, Ltd., Nottingham, by Mr. S. J. Pentecost.

Sir John Turney opened his works (Messrs. Turney Bros., Ltd.) where the preparation of various kinds of light leather was shown. The Company treat sheep and goat skins: of the former 2000 dozen English pelts are dealt with weekly. The pelts come to the works shorn of their wool and are steeped in lime water for three weeks before being tanned. Three-fourths of the skins are split after liming, and the lower leathers dressed with cod oil into chamois, the upper being tanned with sumach into split skins ("skivers"). After tanning they are dried and dyed. The degreasing plant, devised by Mr. F. N. Turney, consists of an apparatus on the principle of the Soxhlet extractor; it is capable of dealing with about 36 dozen skins at each operation, the grease being extracted by petroleum spirit, which is subsequently completely recovered. The bacterial process of bating with *erodin* was also shown by Mr. J. T. Wood, its inventor (this J., 1894, 218; 1897, 510; 1898, 1010, and 1899, 990). Refreshments were then served.

Several members were conducted round the city of Nottingham and shown the principal objects of interest by Mr. H. Potter Briscoe (City Librarian): the following places were visited:—St. Mary's Church, the Flying Horse, with adjoining birthplace of Kirke White, Bridlesmith Gate, Wilford, Mrs. Seaver's grounds (with caves of the prehistoric cave dwellers), the Castle Gateway and the Arboretum, a public park of some 17 acres.

A fourth party visited Southwell Cathedral with Dr. Caven as leader. Southwell is about 15 miles from Nottingham, and is the seat of a bishopric. The present cathedral, commenced in 1110 on the site of a Saxon church, became the mother church of the county in the twelfth century, and its Norman nave and transepts still exist. It has a central and two western towers. The choir is in the early English style, and the Chapter House, erected about 1300, is considered the most beautiful in the Kingdom. The partially ruined palace of the Archbishops of York adjoins the cathedral. Tea was taken at the Saracen's Head Hotel, the history of which can be traced back to the reign of Richard II. It claims to be the oldest licensed house in England.

In the evening the Mayor of Nottingham, Alderman Joseph Bright, and the Mayoress, supported by the Sheriff, Councillor Dabell, and the Chairman and members of the Nottingham Section of the Society held a reception in the Castle, at which all the visiting members and ladies were present. The dungeons, Mortimer's hole, and other places of interest in the Castle were illuminated and inspected by the guests.

TUESDAY, JULY 18TH.

HADDON HALL AND CHATSWORTH.

Leaders: Messrs. L. ARCHBUTT, F. J. CARULLA, S. R. TROTMAN, AND J. T. WOOD.

On Tuesday morning, the party left Nottingham for Rowsley, whence they drove to Haddon Hall (by special permission of His Grace the Duke of Rutland), pausing on the way to photograph the famous Peacock Inn at Rowsley. After being photographed on the famous staircase in the garden of Haddon Hall, the interior was visited and much admired. Luncheon was served in a marquee in the park, and afterwards brakes were resumed for the drive to Chatsworth. At Chatsworth the house and grounds were visited by special permission of His Grace the Duke of Devonshire. The sculpture gallery is a special feature of Chatsworth, and contains Canova's bust of Napoleon I. In the gardens is the famous palm house of Sir Joseph Paxton, which suggested the Great Exhibition of 1851, and the cascades and fountains, replicas of which may be seen at the Crystal Palace, were put in action for the occasion.

The water supply comes from a reservoir on the top of the hill, which also works turbines for dynamos to cut the current for lighting the house. Tea was taken at Baslow, and the party then drove to Bakewell and resumed their journey to Manchester through the beautiful district.

In the evening, by permission of the Lord Mayor of Manchester, Dr. G. H. Bailey, Chairman of the Manchester Section, and Mrs. Bailey, assisted by Mr. J. Hübner, Hon. Local Secretary, and other members of the Local Committee, received the visitors at the Art Gallery, which is well-known for its fine collection of paintings.

WEDNESDAY, JULY 19TH.

WORKS OF MESSRS. JOHN RILEY & SONS, HALTON, NEAR ACCRINGTON.

Leader: Dr. R. S. HUTTON.

On arrival at Hapton, Mr. J. E. Riley and Mr. C. Riley received the visitors and Messrs. C. P. and J. Riley assisted in taking them in small parties through the various processes. The neatness and cleanliness of the works are well known. Sulphuric acid bleaching powder and alkali are the staple manufactures. Members were shown the Glover and Gay-Lussac towers from the Gay-Lussac tower the acid is taken to Kew evaporators in which hot air is bubbled through it, extracts the water without boiling the acid. A pure 96 per cent. strength is thus obtained. The salt cake soda processes were next inspected. The salt cake is of thick iron and last from nine to twelve months. The Kessler evaporators, the black-ash revolvers, the Chance sulphur recovery process received particular attention. The party was afterwards entertained to firm to luncheon at the Hall close by. Mr. J. E. Riley, in a speech, explained how improved methods of manufacture had enabled the L-blanc process to hold its own against more recent electro-chemical methods. Mr. J. Parker and Dr. Russell W. Moore returned thanks on behalf of the visitors.

TANNERY OF MESSRS. JOHN ORMEROD & SONS, CASTLETON.

Leader: Mr. FRANK SCUDDER.

The party was received by Messrs. Wm. H. Jackson and John Ormerod, Messrs. John Ormerod, Jr., Mr. R. M. and G. T. Ormerod, and ex-Councillor Hogd of Rochdale. The works were founded by John Ormerod and his two sons in 1868, they forming the whole of the firm for some time. The manufacture of leather belting was first undertaken; in 1874, the roller leather branch was added, and now the works manufacture a greater variety of leather mill stores than any other firm in the country.

The roller skin department shows the whole process from the raw lamb skin after the wool has been removed to the finished leather ready to place on the spinning rollers of cotton mills. The raw material consists entirely of English lamb skins, which must be not more than six months old and be delivered fresh into the tannery. Experiments with other skins have always failed to loss. The lamb season is June to October.

The liming shed has a capacity of 60,000 lamb skins. The skins are carefully sorted, treated in 66 lime pits with milk of lime, and handled frequently till sufficiently softened or swelled. The waste edges are then cut off and are used for making glue, while the loose fleshy parts are rendered by special machinery designed and built on the premises.

Purging.—Skins are washed with clean water, 20 cwt. in a tumbler at a time, to remove lime as much as possible, then a puer of dog dung is added, which further attacks the lime, and depilates or softens the pelts, so that the lime and natural dirt can be removed, by a process termed *scudding*, this being performed on a wooden beam by a suitable knife. The firm claims that this process is as effective as the bacterial process and is more disagreeable to handle.

Drenching.—After scudding, skins are well washed, and transferred to a bran drench, in which they ferment.

and other acids being formed, which further cleanse bleach the skins. When sufficiently drenched, they are gone over with a razor edged knife to remove all this being an absolute requisite for spinning purposes, *finishing*.—The pelts or skins are now ready for tanning, which is effected in paddle vats. When partly tanned, they are placed, 60 dozen at a time, in large hydraulic presses in layers between plates and a pressure of two tons square inch applied to remove all natural grease. The pressure makes the skins very hard, and before using out they are softened by being soaked in water then placed in stocks and beaten. They are then dried thoroughly, drained and hung up to dry. Up to this point the capacity is 20,000 to 25,000 skins per week. The stock rooms often contain 10,000 to 12,000 skins.

Finishing Department, shaving.—The first important part of finishing is shaving. Skins dried in the rough are soaked before shaving. They are then stretched on special machines and dried to suitable conditions. Shaving is done by new machinery of American make, and the leather must be of absolutely uniform thickness throughout. After shaving, the skins are wetted down, struck out by machinery, and finally dried off by hand labour. They are then nailed on to a board to dry, thus retaining all stretch and lying flat. This leaves skins hard and stiff, and to reduce this stiffness they are put through a softening machine using a special attachment designed by the firm. They are passed through the fluffing or emery wheel to smooth the surface and then given a final brush to clear all the surface. Skins are now ready for "finishing proper," and are carefully sorted to suit the various requirements of quality, thickness and colour. For self colours, a dye and seasoning is given and then glazed by machine. Skins are stained to shade and prepared for glazing, and are then self-coloured.

Stock room.—Glazed skins are again carefully sorted to comply with the brands sold, all waste cut off, sorted into the seven various sizes and placed to stock, awaiting sale. Stocks usually kept are 4,000 to 5,000 dozens. The *bell department* was next shown, and after that the *rather loom stores* with the various styles of pickers, straps and straps used on looms. The leather unsuitable for belting is made use of here. *Buffalo pickers* are made from dry buffalo hides imported from Batavia, Singapore and cured raw after liming. These pickers are required of all shapes and sizes for every variety of bag. The hides are soaked until soft, cut to size, and then folded by hand, and then pressed and punched into shape, after which they are dried, soaked in oil under pressure in large iron tanks for weeks, drained, and hung up to season.

After the inspection of the tannery, lunch was served in the Board Room, and afterwards, on the motion of Mr. W. Wiley, seconded by Mr. Charles G. Cresswell, a vote of thanks was accorded to the firm for their reception and entertainment. The party was then driven to Rochdale (where the Town Hall and the grave of John Bright were inspected) to Littleborough. Here a main road in excellent preservation crosses Black Edge. A short paper descriptive of this was read by a member of the firm, and, after a careful examination of the method of paving employed by the Romans, the party returned to Manchester.

VISIT TO MESSRS. SALIS, SCHWABE & CO.

Leader: Dr. J. BÜRGER.

A party of members availed themselves of the invitation of the Directors of the Calico Printers Association, Ltd., to inspect the works of Messrs. Salis, Schwabe & Co., Ltd., Rhodes, near Manchester. Under the guidance of Mr. Crighton, chief chemist to the firm, visitors were enabled to see the different processes, viz., bleaching, preparing, printing (both machine and hand), dyeing (indigo and colours), mercerising and finishing in addition to the engraving of the copper and rollers which attracted most attention. A hearty vote of thanks was passed to the Directors of the Calico Printers' Association and duly acknowledged by Mr. Crighton.

VISIT TO THE SHIP CANAL AND THE MANCHESTER CORPORATION SEWAGE WORKS.

Leader: Dr. G. J. FOWLER.

After lunch a party went to the Pomona Dock on the Ship Canal, where, by the courtesy of the Ship Canal Company, through Mr. Latimer, General Superintendent, they were provided with a large steam tug. Mr. Congreve, Resident Engineer and Messrs. Lowe and Johnston, of the Dock Offices, accompanied the party. The chief point of interest on the way was the large new dock recently opened by the King, and the new transit sheds built in armoured concrete. Time did not permit of a visit to the Salford Sewage Works, but the striking effect of a large area of sewage sprinklers in active operation was pointed out to the visitors. Much interest was shown in the famous Barton aqueduct, where the Bridgewater Canal crosses the Manchester Ship Canal on a swing bridge. The party disembarked at Barton Locks after having passed a hearty vote of thanks to the Ship Canal Company for providing the steamer and to the officials who had accompanied them.

Barton Locks are close to the outlet of the main sewage works of the Manchester Corporation at Davyhulme. At these works the whole of the sewage of Manchester and certain outlying districts, i.e., of a total population of 575,000, is treated in open septic tanks and contact beds. The average dry weather flow amounts to 25,000,000 gallons, the total average flow to upwards of 30,000,000. The works are designed to treat a maximum flow of 126,000,000, or six times the strict dry weather flow as estimated from the water supply. The total tank space has a capacity of about 21 millions. Four tanks of over one million gallons each are reserved for the settlement of storm water, the rest being open septic tanks. There are 46 acres of primary contact beds, in half-acre units, and 26 acres of storm-water beds. A beginning has been made with a provision of secondary beds for a further treatment of the filtrate from the primary beds, chiefly with the object of removing the suspended matter present in the latter. The sludge from the settlement tanks, and the residual sludge from the septic tanks is taken to sea in a specially constructed sludge steamer. The total area of the estate at Davyhulme is 183.5 acres. The visitors entered the works at the outlet end and first inspected the effluent from the secondary bed, which has recently been started, and were thus able to realise the excellence of the effluent which can be obtained when bacterial treatment is fully carried out. This effluent more than fulfils the requirements of the Mersey and Irwell Joint Committee who control the various works on the watershed. Passing up the centre of the works, and viewing the large extent of bacteria beds and tanks on either side, the visitors at the end of their journey were entertained to tea by the Rivers Committee of the Manchester Corporation, who were represented by Mr. Councillor Johnston, Chairman of the Construction Sub-Committee. Dr. Fowler, Consulting Chemist to the Rivers Committee, Mr. G. Ardern, Resident Chemist, Mr. A. B. Ogden, Manager, and Mr. G. F. Walter, Secretary, were also present. Mr. Julian F. Baker, on behalf of the members and visitors, cordially thanked the Rivers Committee. The party were then conveyed to Urmston station and arrived in Manchester about 6 p.m.

Besides the above, visits were arranged to the Municipal School of Technology at which luncheon was provided by invitation of the Manchester Section: the Corporation Electrical Power Station (Stuart Street), and the Corporation Gas Works in Bradford Road (Leaders: Messrs. B. Hart and W. H. Coleman); the Engineering Works of Mather & Platt, Ltd. (Leader: Mr. R. H. Clayton); the Manchester University; and, for the ladies, the Town Hall, Art Gallery, Cathedral, the Cheetham Hospital, and Libraries. Sir Thos. Wardle also kindly conducted a party over the Whitworth Institute, where the Art treasures and fabrics for which it is famed were inspected.

In the evening, the visitors were entertained at dinner at the Grand Hotel. Dr. G. H. Bailey (Chairman elect) presided, and the guests included the Lord Mayor (Sir Thomas Thornhill Shann), Dr. Wm. H. Nichols, Alderman

Sir James Hoy, Sir Wm. H. Bailey, Dr. Hopkinson (Vice-Chancellor of the Victoria University), Mr. J. K. Bythell (Chairman of the Manchester Ship Canal), and Alderman Thompson (Chairman of the Art Gallery Committee).

Mr. Ivan Levinstein, in proposing "The City of Manchester and the Borough of Salford," said that these two centres of industry must in time become one city. Manchester possessed the finest modern university and the best school of technology in Great Britain. The Journal of the Society of Chemical Industry was first printed in Manchester, and its first President, Sir Henry Roscoe, had represented a division of Manchester in Parliament.

The Lord Mayor, in replying, promised the Society a hearty welcome on the occasion of their visit to Manchester next year.

Sir Wm. H. Bailey replied for the Borough of Salford, and followed by proposing "Our Educational Institutions," which was responded to by Dr. Hopkinson and Sir James Hoy.

The remaining toasts were "The Manchester Section," proposed by Mr. Thos. Tyrer and Mr. A. Gordon Salamon, responded to by Mr. Julius Rübner, and "Our Guests," proposed by the Chairman and replied to by the President.

THURSDAY, JULY 20TH.

The Manchester Section accompanied the visitors to Chester by the Cheshire Lines route, passing through Knutsford, Northwich with its salt mines, and Delamere Forest. At Northgate, Chester, the party was met by Mr. Eustace Carey (Chairman of the Liverpool Section), Mr. Max Muspratt, Mr. and Mrs. Alfred Smetham, and other members. Under the guidance of Mr. Henry Taylor, F.S.A., Mr. Robt. Newstead, Dr. Stollerfoht and Mr. Ferguson Irvine, F.S.A., they traversed the city walls and then the city itself. Several old houses, the "Rows," and an old crypt of the twelfth century, now used as wine cellar to an inn, were visited. After inspecting the carvings of Bishop Lloyd's house in Watergate Street, they were conducted over the Cathedral by Archdeacon Barber, to whom a cordial vote of thanks was accorded at the subsequent luncheon at Bolland's Assembly Rooms. Some of the party, on the way to the river, seized the opportunity to inspect St. John's Church, a fine example of Norman work, the tower of which fell a few years ago and has not been restored. This church, which with its ruined east end covers a very large area, was the Cathedral of Chester, until the dissolution of the monasteries gave Chester a new Cathedral at the expense of the monks.

After luncheon, a trip was taken up the River Dee by steam launch, as far as the Iron Bridge, Eaton Hall, where some strolled through the Duke of Westminster's park as far as the mansion. Tea was then served, another photograph was taken and the party returned to Chester, where they parted with the Manchester Section, and went to Liverpool *via* Rock Ferry and the Mersey Tunnel.

On arrival, the visitors were entertained by the Liverpool Section to dinner at the State Restaurant. Mr. Eustace Carey presided, the principal guest being the Lord Mayor of Liverpool, the Rt. Hon. John Lea. At nine o'clock the Lord Mayor and Miss Gertrude Lea, who represented the Lady Mayoress, received the Society at the Town Hall. Light refreshments were served in the large ball room and an impromptu dance, for which the constabulary band provided excellent music, took place in the drawing room.

FRIDAY, JULY 21ST.

In the morning a party visited the University, and were received by the Vice-Chancellor and Mr. E. K. Muspratt, who conducted the visitors through the buildings. The laboratories, especially that of the Tropical School of Medicine, were of chief interest.

The White Star tender, "Magnetic," lent by the courtesy of Messrs. Ismay, Imrie & Co., awaited the visitors at the landing stage, near which are being erected a huge block of new offices for the Mersey Docks and Harbour Board, on the site of an old dock. By the "Magnetic" a large party went, some to have a sail on the Mersey and to lunch at the New Brighton

Tower, others to disembark at Behington to visit Soap Works of Messrs. Lever Bros. at Port Sun. Brakes awaited the latter party at the landing place, and on arrival at the soap works, they were received by Mr. V. Lever, Mr. J. L. Tillotson, Mr. John Gray, and officials.

The printing department, chemical laboratory, manufacture of boxes and picture frames, the former at a rate of 20,000 a day, fireproof timber stores, quays their electrical transporters, fat, soap boiling, cutting and packing departments were visited in The "Baron" rotary card-box machine receives cardboard from the roll, prints it in five colours stamps out a perfect box ready to be shaped up, box making, the wood is imported in definite sizes branded, and is dovetailed by a machine which twelve to twenty pieces at a time. Four pieces are placed upright at right angles to each other in a machine which forces them together, while the bottom is nailed on by machinery. In the soapery there are 33 oil store tanks, each of 500 tons capacity. Veg. oil, mainly palm oil, with some resin, is saponified with the aid of steam and caustic soda, the soap salts and the glycerin recovered.

The ventilation of all the newer portions of the works is on the "Plenum" system and is consequently effective. The central power station was next visited, with its two great engines and electric installation. It is the new soapery, covering $4\frac{1}{2}$ acres, only started in January last, and now nearly finished. After the fire engines and ambulance, the men's dining with its stage, the library, tennis courts, girls' rooms, auditorium, schools, bath, hostel and canteen were taken in turn. Christ Church, just completed at a cost of £50,000, was presented to his people by Mr. Lever last year.

Luncheon was served at the hostel, and after Mr. Lever explained the system by which he co-operates with his workers. He described it as prosperity sharing, as distinguished from profit sharing, which latter he considered a failure. The profits of prosperous works were devoted to the erection of houses in the village which now covered more than 100 acres. The rents were devoted to all social objects, save those of religion and politics; the maintenance of gardens, collective action had given better results than individual effort; the employees' benefit fund; the widows' pension fund for workmen after 65 years of age, and hearts were wanted as well as hands. As Mr. Lever had remarked, man was not a machine, one only of his best value when one appealed to his heart.

Dr. Wm. H. Nichols, in reply, stated that, after a year's experience of profit-sharing, he felt himself in full agreement with Mr. Lever's system.

Dr. L. Baekeland proposed Mr. Lever's health, and after a few remarks from Dr. Baskerville, the speaker returned to the "Magnetic" and sailed up the Ship as far as Ellesmere Port.

In the evening, train was taken to York, by the C and Dore route through the Peak.

On arrival at York the party was received by Mr. Thos. Fairley (Hon. Secretary of the Yorkshire Section), Mr. S. H. Davies, Mr. Basil Hill, and other members.

SATURDAY, JULY 22ND.

Two parties were organised, one visiting the cocoa works of Messrs. Rowntree, Ltd., the other devoting its attention to York antiquities. On arrival at the cocoa works the party was received by Mr. B. Seeborn Rowntree, Mr. Arnold S. Rowntree, and some of the officials, and conducted through the later stages of chocolate manufacture, each lady receiving a memento in the shape of a chocolate. Meanwhile the second party had been received by Dr. Tempest Anderson within the grounds of the Yorkshire Philosophical Society, and were taken to St. Leonard's Hospital, a portion of the Roman wall and the Hospitium, now turned into a museum of fossils and other antiquities. St. Mary's Abbey Church was next visited, and all were surprised to find that the almost complete destruction of this beautiful church, dated, not from the time of Cromwell,

om it is customary to attribute most of the van-
in this country, but from the beginning of the
entury. The King's Manor House, now occupied
a Yorkshire School for the Blind, was next visited,
the guidance of Mr. A. B. Norwood, the Super-
intendent. This is on the site of the house previously
ied by the Abbot of St. Mary's, and was built by
VIII., out of Abbey materials. James I. was
ained here by the Lord President of the North
way to London in 1603, and Charles I. resided at
nor for some weeks during the civil war, and held
liament. Fifty years later it became a Royal Mint,
300,000 being coined there. In 1833 it was acquired
present purpose as a memorial of William Wilber-
the philanthropist.

h parties then united for a visit to the Minster, where
were met by Mr. T. B. Whytehead (Chapter Clerk).
rst mention of York Minster dates back to the year
hen a small wooden church was built for the baptism
King of Northumbria. In 1215 the present Cathedral
egun, and it was completed and re-consecrated in
1248.

In 1829 a madman set fire to the choir and utterly
yed the roof, the organ, the choir stalls, and
of the stained glass. Another fire in 1840
yed the roof of the nave and the south-west tower
ts peal of 10 bells. The crypt contains portions of
diapered Norman columns and walls in perfect
vation, showing how little hesitation the medieval
rs had in overthrowing the work of their pre-
ors. The transepts are Early English (1225-1235),
ve and Chapter House are "Decorated" (1280-1340),
the choir and the towers are "Perpendicular"
(1470). The length of the Minster is 519 ft., the
d tower 213 ft. high, the width of the nave 139 ft.
videst in the country), and the great east window is
rgest Gothic window in the world which contains its
al stained glass. There is more than half an acre
dieval glass in the Minster, more than is contained
y similar edifice. The Minster is admitted to be one
f finest Gothic buildings in the world.

e visitors then drove round the city walls and
s" to Clifford's Tower, which was originally
keep of York Castle, and stands upon an
ial hill, and thence to the Guildhall, originally
the Common Hall of the ancient guilds of St.
topher and St. George, but granted by Edward VI.
e City. Here the members were received by the
Mayoress, Mrs. Wragge, and were entertained at
by Mr. B. Seebohm Rowntree. After lunch, Mr.
tree gave an address of welcome to the Society, to
the President, and Dr. H. W. Wiley replied. Prof.
ry then proposed the "Yorkshire Section," and
Thos. Fairley replied.

ain was then taken to Ripon, whence the party drove
ountains Abbey, which lies some three miles away
valley secluded within the park of Studley Royal,
seat of the Marquis of Ripon, by whose special per-
son the visit took place.

r. S. H. Davies gave an interesting account of the
dation and history of the abbey, of which the following
summary:—

he Abbey belongs to the great group of Cistercian
ys, founded in the twelfth century, and was an
oot from St. Mary's Abbey, York, by monks
desired a stricter discipline. The present buildings
d the cloister were completed in 1180, and Abbot
a of Kent completed the eastern end with its special
sept, called the "nine altars," between 1220 and
7. Quite at the end of the fifteenth century large
eried windows were inserted in the east and west ends
he church, and Abbot Huby built the great tower
een 1494 and 1526. The Abbey was suppressed in
1539, but, after being unroofed and dismantled, was other-
wise left intact. It remains the most imposing and
ructive ruin of its kind. A little to the west stands
picturesque Fountains Hall, built, at the expense of
e of the Abbey buildings, about 1600.

a the great cloister the party were photographed, and
a partook of tea in the monks' "cellarium," which
till intact. Ripon was regained by brake, and the
ty then left for Newcastle.

SUNDAY, JULY 23RD.

On Sunday morning the members went by train to
Durham, and attended service in the Cathedral. Arch-
deacon Watkins, in the course of his sermon, offered
a welcome to the Society on behalf of the Cathedral
authorities. After service, a stroll was taken along the
banks of the Wear, round the rock on which the Cathedral
stands. At lunch, in the Town Hall, Profs. Chandler and
Mabery and Dr. Russell Moore took the opportunity to
thank the Newcastle Section for its hospitality. After
lunch, Dean Kitchen conducted the party round the
Cathedral, telling them its history, and especially dwelling
upon the legends of St. Cuthbert and the work of the
Venerable Bede. The chapter house and library were
also thrown open. The library is chiefly housed in the
Monks' dormitory and refectory, and contains a number
of MSS.

Durham Cathedral is one of the finest and most com-
plete examples of Norman architecture in England. Of
the structure, only the transepts at the extreme east,
called the Chapel of the Nine Altars, and the upper part
of the central tower are of later date, though decorated
windows, some of them of poor design, have replaced in
some instances the older and smaller Norman ones. The
Galilee, a species of Lady Chapel, placed, contrary to rule,
at the west end of the Cathedral, and built about 1175,
shows traces of Saracenic influence, particularly observable
in the light clustered columns and delicate mouldings on
the arches.

Durham Castle, on the north of the Cathedral, is now
the home of University College, one of the two residential
Colleges of the University of Durham.

The members then returned to Newcastle, and in the
evening attended service in the thirteenth century church
of St. Nicholas, which now serves as the Cathedral, the
crowned tower of which, 450 years old, is the pride of
Tyneside. Canon Gough, the vicar, preached, and, after
service, Mr. J. E. Jeffries, the organist, gave a special
recital on a very fine organ.

MONDAY, JULY 24TH.

In the morning the visitors were shown the keep of the
"New Castle on Tyne" by Mr. Oliver Heslop, President
of the Newcastle Society of Antiquaries. The castle
is best approached by the "Black Gate," the lower
part of which dates back to Henry III. The castle was
"new" in the reign of William Rufus, but the present
keep was rebuilt by Henry II., though in Queen Elizabeth's
time it had already become "old and ruinous."

Accompanied by Mr. John Pattinson, Mr. J. C. Rollin,
Dr. J. T. Dunn and party, Mrs. Henry Louis, Mr. W. H.
Sodeau, Drs. Garrett, Smythe and Hall, Mr. Arnold Spiller,
Mr. and Mrs. Trobridge and other members of the New-
castle section, the party then embarked upon the steamer
"J. C. Stevenson," lent for the occasion by the Tyne
Commissioners, for a trip down the river to Tynemouth.
The visitors were particularly struck with the activity
of the shipbuilding industry as they went along, and
repeatedly called attention to the number of ships lying
in the river. Tynemouth breakwater was reached about
noon, and the members then proceeded to the Bath
Assembly Rooms for lunch. After lunch Prof. V.
Coblentz expressed the gratitude of the American
members for their reception, and Dr. Dunn, in the absence
of Prof. Louis, Chairman-Elect of the Section, replied on
behalf of the Newcastle Reception Committee. Mr.
Thos. Tyrer then proposed the health of Mr. John
Pattinson, as the representative of the old Newcastle
Chemical Society, which had cast in its lot with the
Society of Chemical Industry in days when success was
by no means assured. Mr. Pattinson, in reply, expressed
his gratification in seeing members from a distant shore
which he himself, despite his age, by no means despaired
of visiting in the future.

The visitors then returned to the steamer and proceeded
to Jarrow.

PALMER'S SHIPBUILDING AND IRON CO., LTD.

On arrival the visitors were received by Mr. Malcolm
Dillon, General Manager, Mr. Upton, Manager of the Blast

Furnaces and Rolling Mills, and other officials, and were taken to see pig iron tapped from the blast furnaces, several types of which were standing side by side and served to show the evolution which these furnaces have undergone of late years. Then passing through the boiler shop, where water-tube boilers for destroyers were shown, they proceeded to the steel works, where bars were rolled before them. Next came the engine building shops and the shipyard, where lay the "Lord Nelson" battleship, in course of construction. After being photographed, by courtesy of the firm, the party was entertained at tea. Mr. Malcolm Dillon, in offering a welcome, said that at Palmer's iron ore entered at one end and came out a finished ship at the other. Mrs. E. Byrnes and Mrs. M. Toch responded on behalf of the visitors, and then Dr. H. W. Wiley, in expressing appreciation for the reception given to them, said that though shipbuilding might be said to have driven out chemical industry from the Tyne, yet applied chemistry was so integral a portion of the process of building a ship that without its aid no such battleship as they had seen would be possible. It was therefore right and meet that the Society should be entertained at Jarrow, and that it should propose prosperity to Palmer's Shipbuilding Co. They were close to the spot where Glover lived, where Weldon's discoveries were made, and even to the old home of the Washingtons. They came there on a pilgrimage to a shrine hallowed in both countries, and they pledged the old country and their own to stand shoulder to shoulder to secure the peace of the world. The Chairman then gave "England and America," which was drunk with great enthusiasm, and souvenirs of the "Lord Nelson" were presented to each member.

The visitors then returned to Newcastle, and later on took train for Edinburgh, by way of Berwick-on-Tweed and Dunbar, much of the route lying along the sea coast.

On arrival, the party were received by Mr. David Perry (Chairman Elect of the Scottish Section) Mrs. Perry, Dr. Thos. Gray (Hon. Local Secretary), Mr. and Mrs. J. G. Flowerdew Lawson, and other members.

TUESDAY, JULY 25TH.

In the morning they drove round the old town, visiting Holyrood Palace, when a photograph was taken in the ruined chapel, and where the room and relics of Mary Queen of Scots roused much interest. Thence, along Canongate with its wynds and closes, they went to St. Giles Cathedral, restored by the munificence of Dr. Wm. Chambers, and then to the Castle. Here were shown the Regalia of Scotland, the room where James I. was born, and a curious small Norman Chapel, almost the sole relic left of the earliest period. The view from the Castle, comprising the Firth of Forth with its gigantic bridge, the coast of Fife, the island of Inchkeith, and the Lothians, was on this occasion unusually perfect and far reaching.

Thence some found their way to the Parliament House, others to John Knox's house, and others to the National Gallery where Raeburn's portraits, now so valuable, abound. After lunch Mr. Perry welcomed the members, and the President and Prof. C. F. Chandler, in responding, acknowledged the hearty way in which the visitors were being received.

Then they drove out to the Forth Bridge, a structure one mile and one fifth long and 450 ft. high, built on the cantilever principle, and returned through Dalmeny Park, by special permission of Lord Rosebery.

In the evening the Lord Provost (Sir Robt. Cranston) and Lady Cranston gave a state reception at the Council Chambers, when a concert was given. Pipe Major Wilson, of the Highland Light Infantry, assisted by Piper Johnstone, gave selections on the bagpipes, and the latter performed Highland dances in honour of the visitors.

WEDNESDAY, JULY 26TH.

The visitors went to Callander by rail, passing through Linlithgow with its ruined palace and abbey church, and Stirling, with its famous Castle and Wallace monument. From Callander, brakes took the visitors by Loch Venachar and Loch Achray to the Trossachs Hotel, where lunch was served. Then they drove through the

Trossachs proper, a deep and wooded glen no more than a mile in length, to the foot of Loch Katrine or Loch the Caterans, so named from its robbers, of which Robt. was a type. This loch is now Glasgow's water supply, but, beyond a slight elevation in level, there is no change in its appearance. Stronachlachar was reached by steamer, and then a five miles' drive over the water under the shadow of Ben Lomond, brought the party to Inversnaid on Loch Lomond, where a photograph was taken in front of the waterfall. Steamer was then taken down the Loch to Balloch, whence the Caledonian Railway brought the party to Glasgow.

THURSDAY, JULY 27TH.

The final trip of the excursion started from St. Enoch Station, Glasgow, for Prince's Pier, Greenock, where the party accompanied by Lady Primrose, wife of the Provost, embarked on the "Juno," a fine new steamer belonging to the Glasgow and South Western Railway. The weather, as indeed it had been throughout the trip, was fine, with a pleasant breeze.

The route taken was up Loch Goil in the first instance, as far as the ruins of Carrick Castle. Then the steamer ran rapidly down the Clyde, past the Holy Loch, where some obsolete battleships were seen in the distance. Hunter's Quay, with its yachts, Dumoon and Inverclyde, to Rothesay Bay with its view of Loch Striven. The Kyles of Bute were neared more obsolete battleships—"Alexandra," "Dreadnought," "Collingwood," "Pareil," and "Iron Duke"—silent and deserted, passed. It is but a short time since some of these ships looked upon as the strength of the British Navy, required some moral courage on the part of Sir Fisher to place them upon the scrap heap, especially large sums had but lately been spent to make them efficient. Luncheon was served on board, and after meeting took place in the saloon, Dr. Wm. H. Nichols took the chair. Mr. David Perry opened the proceedings by offering a welcome to the visitors, and then Mr. C. Bloede, of Baltimore, on behalf of his fellow visitors, returned thanks for the hospitality shown to them both in England and Scotland during their visit. In conclusion, he said the American visitors felt that slight recognition was due to those who had organized the meeting and excursions, and he wished, on their behalf, to present to Mr. A. Gordon Salamon (Chairman of the Executive Committee), Mr. Julian L. Baker (Secretary), Mr. Thos. Tyrer and Dr. J. Lewkowitsch (members of the Hotels and Excursions Committee) with handsome flower bowls. Messrs. Baker, Tyrer, and Lewkowitsch briefly acknowledged the presentation. Mr. A. Gordon Salamon being prevented from being present, the steamer meanwhile passed through the Kyles and arrived at the Island of Arran, the property of the Duke of Hamilton. Until recently "feuing" has been restricted on this island, but now some building is permitted. Return was made to Greenock by the Firth of Clyde.

In the evening the Corporation of Glasgow gave a reception in the City Chambers, one of the finest Town Halls in the kingdom. The guests were received by the Lord Provost, Sir John Ure Primrose, Lady Primrose, and the magistrates in state. After the reception the Lord Provost, the magistrates, and some of the principal members of the Corporation assembled on the dais in the great hall, while the Lord Provost briefly explained to those invited to meet the Society what purpose the Society of Chemical Industry fulfilled, and why Glasgow delighted to do it. He gave instances of the part which chemistry played in municipal matters, and alluded to the band of workers in the laboratory who investigated day and night the inner alchemy of Nature for the benefit of humanity. Dr. Wm. H. Nichols, in reply, said that the name of the 4,500 members of the Society, he thanked his Lordship for his kind references to the science which they all followed and loved. It was good to select a subject and treat it in such a manner. H.M. the King, at an interview which he accorded to some of their representatives, touched upon the same thing very much to their pleasure. From London to Glasgow they had been entertained everywhere, and everything had been done intelligently and well.

anked the Lord Provost. Mr. David Perry also
ed the Corporation of Glasgow, and Dr. Russell W.
proposed, and Mr. Paul Rottenburg seconded,
of thanks to the Lord Provost.
excellent concert followed.

Photographs at nearly all places, with the exception
at Jarrow, were taken by Messrs. Walter Baker &
Foll Street, Derby Road, Nottingham, from whom
may be obtained.

THE GUIDE BOOK.

s guide was for the most part written by Miss E.
ls, B.A. (Lond.), under the supervision of Mr.
L. Baker (the Hon. Secretary of the London Section),
hom it was edited at the request of the Executive
nittee. Every effort was made to collect the informa-
contained therein from reliable sources, and, in
valuable assistance was received from the various
Local Secretaries of the Country and Scottish
ons, Mr. T. Tyrer and others. Mr. T. Tyrer, Mr. B.
ran, and the Manchester Chamber of Commerce, and
s. Methuen & Co. also kindly lent blocks.
is hoped that it will form as interesting a souvenir
meeting as it was found a useful guide at the time.

New York Section.

ing held at Chemists' Club, on Friday, May 19, 1905.

DR. RUSSELL W. MOORE IN THE CHAIR.

EXTRACTION OF TANNIC ACID FROM THE POINT OF VIEW OF THE DYER AND CALICO PRINTER.

BY WALTER S. WILLIAMS.

e tannin materials of the modern dyer and calico
er are commercial tannic acid, sumach, catechu,
gambier, the first two being by far the most im-
nt.
mach is found in the market either as a powder, or
i extract. The powder contains 15-20 per cent.
e acid and carries as well a certain amount of colour-
matter, which makes it unsuitable as a mordant for
e using either clear or very light shades on cotton fibre.
ries from a bright yellow to light green coloured
el, which should be free from lumps and other
ations of excessive moisture.
mach should be examined for tannic acid, moisture,
and adulteration. For the latter the microscopical
ination of the leaf cuticles offers a ready method of
ection. This method, due to Lamb (Jour. Soc.
s and Colourists, XV., p. 60, and XX., p. 265),
also been treated at length in an excellent article by
P. Stman, recently published in this Journal (1905, p. 231).
Mixture and ash may be determined in the usual manner,
tannic acid by the analytical methods.
e extract of sumach is also much used, and more or
le bleached forms may be had under the name of colour-
e extracts of sumach. The general method of rating
e by gravity offers no criterion as to the actual
in contents; an analytical or practical test is neces-
to determine their true mordanting value. As the
d: uses smach principally for dark shades, and usually

with iron salts as a fixing agent, a comparative dyeing
test similar to the actual dyeing process will, if carefully
conducted, answer all requirements.

Catechu, gambier and a few similar bodies are used by
the dyer because of the colouring and other valuable
properties they possess, rather than for the tannin they
contain. They are best examined by running a small
practical trial in the dye house or laboratory.

Commercial tannic acid is most commonly obtained by
the extraction of gall nuts, the purest acid being from
colouring matter being that derived from Chinese or
Japanese galls. There are several varieties to be dis-
tinguished, the three most common being obtained
respectively by extraction with ether, alcohol and water.
Tannin extracted with the aid of ether comes in the form
of a light, fluffy powder, and is apt to be purer than that
extracted by the other two methods. The extracts made
with alcohol or water are evaporated to dryness, and the
resulting mass ground to a powder giving the usual tannin
of commerce. The latter grade is liable to be much con-
taminated with colouring matters, fat, and resinous or
tarry matter, frequently so much so as to render it unfit
for anything but the crudest work. Acetone is also used
as a solvent in extracting tannin.

A new tannin extracted in this country by a secret
process has recently attracted much attention, both at
home and abroad, because of its great purity.

The so-called "Tannic Acid Crystals" owe their crys-
talline form to the method of drying, being forced in
small drops while still moist on to a revolving hot cylinder.

For the qualitative recognition of tannin materials
the tables and method of procedure given by Procter
(this J., 1894, p. 187) will be found to meet all requirements
with any but mixed samples.

Besides gallotannic acid, the commercial article contains
varying amounts of glucose, chlorophyll or other colour-
ing matter, volatile oil, resinous or tarry bodies, ellagic
and gallic acids, and a certain amount of moisture. Starch
and dextrine may be present as a wilful adulterant. The
gallotannic acid usually runs from 70 per cent. to 90 per
cent., but is frequently found as low as 50 per cent.
Allen has mentioned rare samples which, in his experience,
have consisted entirely of gallic acid.

Sampling is the first important step in tannin examina-
tion, for it will be readily seen that unless the samples
are entirely representative of the lot in question the
most careful analysis can give only meaningless results.
As tannin is almost universally shipped in barrels, it
offers a ready means of sampling. If the lot is small
a sample should be drawn from each barrel, using a tube
which will reach from end to end of the barrel, and insert-
ing it at a point about one-third the diameter from the
outer edge of the barrel. From larger lots each third
barrel may be selected, and from very large lots one barrel
in five may be sufficient. The samples so drawn should be
well mixed, worked down to a convenient size by quarter-
ing in the well-known manner, and kept in air tight
bottles until examined.

Moisture, if strictly accurate work is desired, must be
determined by drying *in vacuo* over sulphuric acid. Few
works laboratories, however, are fitted with the necessary
apparatus, and in lieu of this the results obtained by
drying the sample 2-2½ hours at 95° C. will be found
sufficiently accurate for most requirements. The sample
for drying should not form a layer of more than 7 mm.
in thickness in the weighing bottle, and after drying
should not be used for the subsequent analysis. The
results obtained by using dried portions of tannin will
be found to vary among themselves, and from values
found by using undried tannin and calculating the dry
tannic acid from previous tests.

In using the pure tannic acid for standardisation of
solutions, or, when analysing the commercial product,
I have found it best to weigh out at one time from a glass-
stoppered bottle the several portions needed both for
the moisture determinations and for the solutions for
tannic acid titration. The dry tannin is then taken as
the same percentage in all the weighings. The effect of
long drying is shown by the table given below. The
results are the averages obtained from two different pure
tannic acids, and from one good commercial grade. The

somewhat slower drying of the latter would seem to be explained by its greater compactness.

Effect of Time in drying Tannic Acid.

Length of drying.	Weights in percentage of original weights.

Some tannins examined by the author, evidently water extracted, have been found to contain such large quantities of resinous or tarry matter, accompanied with chlorophyll, as to be highly objectionable to either the dyer or printer. A quick test for such bodies may be made by boiling up with an equal weight of acetic acid and setting aside to cool. If present in any quantity, a thick sticky mass will collect on the top of the solution.

The other bodies mentioned as present in tannin are of slight importance to us, with the exception of gallic acid. This acid is by far the most prevalent and least to be desired of the non-tannins found in the tannic acid of trade. Tartar emetic forms with gallic acid a white precipitate, but this compound is entirely devoid of lake-forming properties with basic dyestuffs. Gallic acid is also only slightly absorbed by cotton fibre.

It is therefore on the accurate separation of gallic from the gallotannic acid that the usefulness of a process of analysis depends.

I think all will agree that in spite of the many and diverse methods described for the analysis of tannin materials, no general method has been devised which is both simple in manipulation and reliable. A process for the estimation of commercial tannic acid would appear to be a much simpler problem, but is still apparently far from solution. Those who wish to consult the various methods proposed will find them fully described in Allen's "Commercial Organic Analysis," Vol. III., Part I., page 69, *et seq.*, in the Journal of the Soc. of Dyers and Colourists, or in the files of this Journal.

The standard method of tannin analysis, as adopted by the International Association of Leather Trades Chemists, is the well-known hide-powder method of Simand and Weiss, of Vienna, using the hide-powder filter devised by H. R. Procter. This process is probably the most used, and for the leather industry is undoubtedly the most rational. The separation of gallic acid is not complete, however, and the process is not as accurate in this respect as the gelatin separation. Procter states that hide-powder absorbs 78 per cent. of the gallic acid present in a 1 per cent. solution; this being the strength of tannin solution used for this method of analysis.

An equally important process for the estimation of tannin is the oxidation or permanganate method, first proposed by Löwenthal and modified by Procter, Hunt and others. I will have more to say of this process later.

Many volumetric processes have been proposed which attempted to imitate the practical methods of application of tannic acid in dyeing, as the hide-powder method simulates the tanning of leathers. The first of these was described by Gerland, who titrated the tannin solution with tartar emetic in the presence of ammonium chloride, which prevented the precipitation of gallic acids. Richards and Palmer (Silkman's American Journal Science (3), XVI., 196, 361) improved the process by substituting ammonium acetate for the ammonium chloride, and devised a new method for ascertaining the end point.

F. Becker (Journal Soc. Dyers and Colourists, 1, 1900) describes a method of determining tannin by the use of a solution of methyl violet containing 5 grms. per 50 c.c. of this solution is diluted with 450 c.c. water at 50° C., and titrated with a 1 per cent. solution of tannin.

E. Guenez proposes a method of tannin estimation based on the precipitation of a standard solution containing 12 grms. of tartar emetic and 1 gm. Poirier's 4 J. E. in a litre, by titrating with the tannin solution.

These three methods and many similar volumetric processes have doubtless been used as comparative methods with some success, but the difficulty of finding the end point and the varying reactions under slightly different conditions make the results not accurate, at least, than those from a well-conducted dyeing test.

After numerous trials of promising methods, I found the modification of the permanganate process described by Bertram Hunt (this J., 1885, p. 26) most satisfactory. I will give briefly the strong solutions found to give the best results with tannin and will refer you for further details to the original article:—

1—1 1/4 gm. of the tannic acid is weighed out and made up to 1 litre. 15 c.c. of this solution, 30 c.c. of a 1 per cent. solution, and 750 c.c. of water are placed in a porcelain evaporating dish and titrated with a permanganate solution drop by drop with constant stirring.

The indigo solution is made by dissolving 5 grms. of pure sodium or potassium sulphindigotat in 100 c.c. of water, adding 50 c.c. concentrated sulphuric acid, and making up to 1 litre. The purest synthetic product should be used, as the presence of indirubin or other impurities prevents the formation of a satisfactory end-reaction.

The permanganate solution contains about 1 gm. per litre. The saturated salt solution is made by adding pure sodium chloride in distilled water and adding each litre 50 c.c. of concentrated sulphuric acid.

For the separation of tannins and non-tannins, 25 c.c. of the tannin solution are run into a flask together with 25 c.c. of a freshly filtered gelatin solution, 2 grms. of 100 c.c. The flask is well shaken, 50 c.c. of the saturated salt solution run in, and 5 grms. of pure barium sulphate added. The flask is again well shaken, and after five minutes the contents filtered; the filtrate should be perfectly clear and free from tannin. For the titration of non-tannins 60 c.c., equal to 15 c.c. of the tannin solution, are taken. The best gelatin obtainable has been given a slight quantity of oxidisable matter reacting with the permanganate. This necessitates a blank determination in which the 25 c.c. of tannin solution is replaced by the same amount of distilled water.

The permanganate solution may be standardized against oxalic acid and the report given in terms of either the gallotannic value figured by using the equivalent values of Neubauer or Ishikawa (Chemical News, 11, 274). The more rational method from our standpoint is the use of either pure gallic acid or pure tannin, which are titrated in the same manner as the tannin, and thus cancel errors due to different rates of oxidation. For gallic acid Procter gives the value of 1 gm. as equivalent to 1.35 grms. gallotannic acid. It is impossible to obtain tannic acid free from gallic acid and other non-tannins, and the results must be corrected for these impurities. Von Schroeder allows for the higher reducing power of gallic acid in tannic acid, found to contain 5 per cent. non-tannins, by dividing the result (c.c. of permanganate solution) by 1.05. In using gallic or tannic acids as standards the moisture should be determined by the method already described.

The table following shows the values determined by the above methods with the same permanganate solution. The set of figures marked "B" were obtained at an interval of several years with different reagents and solutions throughout, and figured to the same strength of permanganate solution from their oxalic equivalent. The exact agreement of the tannic acid value from tannin made by different firms is more than expected from every group of trials.

Equivalents for 100 c.c. of Permanganate Solution by Different Standards.

A quick comparison of values the dyeing test offers as a approximate substitute for the analytical methods. In cases where the tannins are more accurately determined, this test forms a valuable adjunct if conducted with the necessary precautions. Besides showing at a glance the mordanting power of the tannin, it gives as to the clearness and brightness of the resulting shade. In the past years I have used an improvement on this test for all preliminary examinations of tannic acid. The process requires a small trial printing machine with a roll engraved for a rather broad stripe. The results are more accurate than those obtained from the dyeing test, and the trials may be quickly and easily made. In describing the process I shall give the temperature and length of different treatments found most suitable for my own use, but these may be changed as reason to meet varying conditions, it being only necessary to adopt a definite mode of procedure for all trials which are to be compared.

The printing paste containing the tannin to be tested is as below, printed on bleached cotton cloth and

1 oz. of tannic acid is dissolved in 1 oz. acetic acid and 3 oz. water, and the solution added to 12 oz. of water. The thickening is made by boiling 4—6 lbs. light British starch in 1 gall. of water, the amount of gum necessary depending on the proportion of unconverted starch it

contains. A consistency is required which will give a full, sharply-cut impression when printed.

All the patches to be compared are then steamed in any convenient manner, and fixed by working 15 minutes at 50° C. in a bath of tartar emetic containing 1 oz. per gall. The swatches are then rinsed two minutes in cold and two minutes in hot water, and dried. This treatment should wash out practically all of the gum, leaving only the tannate of antimony and such colouring matter as is present in the tannins. A part of each trial being saved for future comparison, the remainder of the swatches are dyed in one bath with an excess of a red shade of methylene blue using the usual dyeing assistants. On completion of the dyeing the patches are removed from the bath, rinsed in cold water and then five minutes in hot water at 90° C., soaped lightly, rinsed, and finally dried.

The printed portions of the cloth will be found well dyed, while the rest of the fabric is only slightly stained. A comparison of the printed parts will give a very fair idea of the mordanting value and clearness of tone to be obtained in practice.

The results by this method have been found to be in perfect accord with the values obtained by analysis, though not of course susceptible to such a fine degree of accuracy. It is not possible in practice to distinguish much nearer than 5 per cent. in colour matching. If desired, a set of standards may be prepared by using a pure tannic acid of known strength, but it will be found even more satisfactory to keep a large sample of a good tannin, previously analysed, in a well stoppered bottle and to test all new tannins directly against this sample.

It may be of interest to state that when the tannic acid in one of these trials is replaced with gallic acid no trace of the basic dyestuff is fixed on the fibre. The statement of W. P. Dreaper that "the total tannic and gallic acids give, from the dyer's point of view the 'mordant value' of the extract" (Jour. Soc. Dyers and Col. XX., 224) can hardly be taken as well founded. I call your attention to this discrepancy only because I wish to commend most highly the Dreaper improved process as a step in the right direction. I am also glad to welcome as an advancement the process of Parker and Payne (this J., 1904. p. 648). These methods, based as they are on the formation of metallic compounds with the tannic and gallic acids, point out the directions in which we must look for future improvements in tannin analysis, namely, the substitution of a more definite reaction for the precipitation with gelatin, hide powder, or other colloid bodies.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—8s. each, to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—1s. each, to the Secretary of the Society.

French.—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs Bourgeois, Paris (3^e).

I.—PLANT, APPARATUS, AND MACHINERY.

ENGLISH PATENTS.

Mixing either Granulated Powdered or Similar Substances or Fluids; Apparatus for —. C. Duckworth, Colne. Eng. Pat. 19,092, Sept. 5, 1904.

THE claims are for improvements in mixing apparatus described in Eng. Pat. 16,230 of 1901 (this J., 1902, 1224). These improvements consist in constructing the mixing cylinder in halves, which may be taken apart for filling or emptying, in providing an internal tube for heating by hot air or steam; and in arranging a valve at one end of the cylinder which automatically opens when that end is uppermost.—W. H. C.

Extracting Moisture from Air or other Gases for use in the Arts; Method of —. J. Gayley, New York. Eng. Pat. 865, Jan. 16, 1905.

THE patent refers to apparatus for drying air, described in Eng. Pats. 20,207 of 1894 (this J., 1895, 40) and 13,892 of 1904, in which the moisture is removed from the air by passing it through a series of refrigerating chambers. The claim is for the method of rendering one of the chambers inoperative for a time and passing the whole or part of the incoming warm air through it to melt off the frost deposited on the cooling coils. This air may then, by means of a deflector, be distributed in any desired proportion to the other chambers.—W. H. C.

UNITED STATES PATENTS.

Vacuum-Pan. J. Abraham, Assignor to Milwaukee Evaporator Co., Milwaukee, Wis. U.S. Pat. 794,831, July 18, 1905.

A CYLINDRICAL vessel is divided by two tube-plates into three chambers, the upper being the evaporator, the middle the heating chamber, and the lower the settling chamber. The tube-plates are connected by tubes passing through the heating chamber, which is divided into sections by vertical baffle plates, arranged between successive rows of tubes and terminating short of the upper and lower tube-plates alternately. In this way the heating medium, which enters at one side and leaves at the other, is compelled to take a zigzag path. A deflecting plate is placed in the evaporating chamber over the upper ends of the tubes through which the liquid circulates. When several pans are connected in series, the heating

chamber of the first is fed with steam, but the succeeding ones are fed with vapour taken from the upper part of the previous evaporating chamber. The liquid is fed into the first evaporating chamber, and after concentration it collects in the settling chamber, from which it is carried to the evaporating chamber of the next pan. From the last settling chamber the concentrated liquid passes through a strainer, whilst the vapour from the last evaporator passes through a condenser, provided with a pump.—W. H. C.

Vacuum-Pan and Condenser; Combined —. J. L. Rogers, Detroit, Mich. U.S. Pat. 795,650, July 18, 1905.

l A acting as a condenser is arranged in the of the vacuum-pan D and has a delivery through f the pan, for the condensed liquid passing, as the fig. Jets of condensing fluid are supplied idenser from a reservoir B situated at the top n. The size of the jets can be regulated by two circular perforated plates C, which can be actively to one another, thus altering the size of rations and consequently of the jets of cond- uid.—W. H. C.

FRENCH PATENTS.

Acid; Impts. in ——. G. F. D. Ceaglio.
Fr. Pat. 351,952, Jan. 17, 1905.

liquid (acid) to be elevated enters by the pipe b the back-pressure valve c, and flows through the a and the pipe d into the egg or reservoir e. When the latter is full, the acid fills up the pipe d and the a and lifts the float h off the supports t. As the s it closes the air escape opening n by the valve eed by the rod i through the pipe f, which serves et the float-box a with the valve-box g. At the e the lever k is pressed upwards and opens the ed-air valve u; the compressed air then enters by o and the valve u, and passing to the float-box a egg e by the pipes f and r, forces the acid up the pipe s. The float soon falls back on to its supports e pressure of the air keeps the valve m closed. level of the acid in e falls below the bottom of the when the air escapes and the pressure falls. The then drops and u closes, the air supply is cut off, c-pressure valve c opens and the vessel fills again. —W. H. C.

Heating Drum. Maschinen-Bau-Anstalt, B. —, G.m.b.H.
Fr. Pat. 351,523, Feb. 15, 1905.

A ROTARY heating drum, through which the liquid to be heated circulates, has its surface contracted at intervals, so as to form a series of grooves or corrugations. The heating coils, which partially or entirely embrace the drum, are placed in these grooves, and, being surrounded

on three sides by the liquid to be heated, a very economical utilisation of the heat is obtained.—W. H. C.

Centrifugal Separators; Method of Fixing the Internal Fittings of ——. J. Mélotte. Fr. Pat. 351,529, Feb. 15, 1905. Under Int. Conv., Feb. 20, 1904.

THE claim is for the method of fixing the distributing wings or vanes in the bowl of the machine by means of springs, placed between the feeding cup and the false bottom of the drum.—W. H. C.

Rectifying, Distilling, and Concentrating Apparatus H. A. Dero. Fr. Pat. 351,530, Feb. 15, 1905.

THE claim is for the use of chains, which are placed in the tubes or columns of rectifying, distilling and condensing apparatus. The greatly extended surface presented by the links of the chains is covered by condensed liquid, which washes the vapours very effectively. Equally good results are said to be obtained with much more compact apparatus than is possible with the bubbling columns in general use.—W. H. C.

GERMAN PATENT.

Furnace; Gas —, for Heating Iron Plates and other Objects. O. Müller. Ger. Pat. 159,910, April 16, 1904.

THE furnace is constructed with two vertical heating channels connected at their ends by transverse channels. The heating channels are provided with niches or recesses having openings, any of which can be placed in communication by connecting tubes with the gas-supply tube or the chimney at will, so that any part of the heating channels can be heated as required. Combustion of the gas takes place in the recesses, and the objects to be heated are not exposed to the direct flame, but only to the hot products of combustion. The gas and air are introduced directly at the place where combustion is effected, so that rapid cooling of the heated objects by the incoming air or gas is avoided.—A. S.

II.—FUEL, GAS, AND LIGHT.

Carbon Filament; New — J. W. Howell. Electrician. 1905, 55, 588—590. Paper read before Amer. Inst. Electr. Eng.

A DESCRIPTION is given of work carried out on carbon filaments baked at a very high temperature. No beneficial change is produced by passing an abnormally high current through an ordinary incandescent filament in an evacuated lamp. The heat must be applied externally by placing the filaments in an electrically heated carbon tube furnace. The "base filament," produced by carbonising the squirted and hardened cellulose, does not undergo any great alteration by baking at these high temperatures. It is only the "treated" filament produced by "flashing," and more particularly the shell of graphite, which is deposited from the hydrocarbon vapour in this process, which by heating to high temperatures (usually 3000° to 3700° C.) becomes "metallised." The chief peculiarity of these "metallised" filaments is shown in the accompanying diagram, which illustrates the variation of resistance of the filament with temperature. The temperature is indicated by the percentage relation of the pressure on the filaments to the normal pressure at which the filament has an efficiency of 3.1 watts per candle. These "metallised" graphite shells, besides giving a marked positive resistance curve, have other physical peculiarities which the author takes to indicate that they consist of a new form of carbon. Lamp filaments taking about 2.5 watts per candle with a useful life of about 500 hours are being produced with a fair degree of uniformity. (See also Eng. Pat. 6959, 1904; this J., 1905, 721.)—R. S. H.

ENGLISH PATENTS.

Fuel Briquettes; Process for the Preparation of Compounds for — B. Wagner, Berlin. Eng. Pat. 351, Jan. 7, 1905.

SEE FR. Pat. 350,579 of 1905; this J., 1905, 794.—T. F. B.

Fuel; Process for Manufacturing Artificial — J. Knops, Aix-la-Chapelle, Germany. Eng. Pat. 4291, March 1, 1905.

SEE GER. Pat. 158,756 of 1904; this J., 1905, 722.—T. F. B.

Burners for Liquid Fuel; Impts. in — J. J. Ker. Liverpool. Eng. Pat. 15,269, July 8, 1904. Also this J., 1899, 478, 904.)

THE burner consists of three concentric barrels, the inner barrel, steam being admitted through the annular space between this and the intermediate barrel, and the air through the space between the latter and the outer barrel. The outer and intermediate barrels mounted together, can be revolved on a screw connection so as to adjust the steam admission valve. The barrel projects beyond this valve, and the oil admission at the rear end of the barrel is controlled by a operated screw valve, the body of which is prolonged side the inner barrel in the form of a spiral scraper. Air admission is regulated by a rotary band, providing apertures which can be adjusted so as to correct more or less with the air ports provided round the of the outer barrel. The surrounding hood, through which air is admitted to the firebox, encloses a rotary fitted with internal deflecting vanes, so that in the of a tube bursting in the boiler, and setting up a pressure of steam, the air supply is automatically cut. The same result may be attained by means of swing opening inwards to the firebox.—C. S.

Gas; Apparatus for the Manufacture of Generator — Roberts and H. C. Anstey, Grantham, Lincoln. Eng. Pat. 18,975, Sept. 2, 1904.

IN the producer, one or more pipes are arranged upright position, passing through the mass of incandescent fuel; the open tops of these pipes are protected by shaped hoods. The fuel which is charged through ordinary hopper falls on top of the hood and fills the space between the pipe or pipes and the wall of the producer; but leaves a free space beneath the hood. The generated passes down the pipes and leaves the producer at the bottom. The hot gas is conveyed through in a vertical boiler, thus raising the steam required by the producer. The air, carrying steam with it, is forced through the boiler into a jacket around the producer, where it takes up heat. The apparatus is especially suitable for bituminous coal.—R. L.

Producer Gas Manufacturing Apparatus. C. B. Eng. Pat. 19,183, Sept. 6, 1904.

IN order to prevent an excess of steam and an insufficient supply of air under the grate in a suction gas producer, when the engine is working on light loads and the valve is suppressed, the apparatus is fitted with a throttle sleeve, to regulate and control the relative proportions of air and steam supplied to the producer. The sliding sleeve is adapted to be moved in telescopic fashion on the suction pipe by means of an attached rack and pinion. The sleeve increases the air inlet space, and reduces the steam inlet space when moved towards the air inlet and vice versa.—R. L.

Gas; Apparatus for Converting Oil into — for C. Heating, and Illuminating Purposes. W. Oliphant and T. Scott, Glasgow. Eng. Pat. 22,917, Oct. 25, 1904.

THE apparatus is fed with oil from a vessel under pressure, a reducing valve controlling the supply automatically. The pressure must be sufficient to force the oil into the evaporator, where it is vaporised by two heaters and mixed with air, which is drawn into the mixing chamber by the suction of superheated gas and heated before mixing.—R. L.

Gas, Air and the like Fluids; Apparatus for Testing — J. Milne and H. O'Connor. Eng. Pat. 15,885, July 1, 1904. XXIII., page 904.

Tetrachlorethane [Acetylene tetrachloride] and Chloroethane from Acetylene; Production of symmetrical — H. K. Tompkins. Eng. Pat. 19,568, Sept. 10, 1904. XX., page 920.

[Carbon] Filaments for Electric Incandescent Lamps and Methods of Manufacturing the same. H. C. Schenck, London. From General Electric Co., Schenectady, N.Y. Eng. Pat. 6959, March 22, 1904.

An ordinary filament which has been "flashed" in red

temperature (2300° to 3000° C.) in an electric arc, and thus permanent changes are produced in its characteristics. Instead of decreasing rapidly as the temperature rises, as do ordinary carbon, such filaments, at the high temperature, show as low a value as 50 per cent. of their cold resistance. If fired at the highest temperatures attainable, they even exhibit a higher resistance when hot than in the cold state, thus behaving similarly to metals. The filaments, a suitably jacketed and enclosed tube furnace, traversed by a powerful electric current is employed. It is claimed that such filaments have a high efficiency and long life.—R. S. H.

UNITED STATES PATENTS.

Seaweeds; Manufacture of —. D. M. Balch, Santa Ana, Cal., Assignor to A. P. Stephens, San Diego, Cal. U.S. Pat. 794,481, July 11, 1905.

The process consists in first drying the seaweed, and then the dried weed with some alkaline substance, and the dried and coated weed is then subjected to a further treatment, which is continued until all the volatile constituents are driven off, and the residue commences to char. The charred mass is lixiviated with water, and with a mineral acid, and then with water, to remove all the soluble salts, and the residue when dried is suitable for use as fuel. The use of some binding material of a combustible character with the residual mass, for the formation of briquettes, is also covered by the claims.—J. B. C. K.

Apparatus Applicable for Burning Liquid —. J. H. Cunningham, Birkenhead. U.S. Pat. 795,200, July 18, 1905.

U.S. Pat. 25,706 of 1903; this J., 1905, 71.—T. F. B.

Regenerative Gas —. C. Ellis, Assignor to Eldred Process Co., New York. U.S. Pat. 795,259, July 18, 1905.

A combustion chamber in a regenerative gas furnace is lined with two pairs of reversing regenerators, in which the gas and air are separately heated. The gas and air regenerators are connected with a part of the air regenerator remote from the combustion chamber, whereby the products of combustion leaving the gas regenerators may enter opposite to the previous direction of the air, and the colder portion of the air regenerators. The gas and air regenerators are in communication with two auxiliary air heaters at each end of the furnace, whereby products of combustion leaving the former may enter the latter. The air heaters are provided for passing air through these air regenerators in a direction opposite to the direction of the passage of combustion gases upon reversal of the direction of gas flow in the combustion chamber.—R. L.

Generator. J. J. Nix, Los Angeles, Cal. U.S. Pat. 795,161, July 18, 1905.

The generator consists of a long horizontal chamber, lined with a series of piers erected on its bottom and extending horizontally. The piers support checkerwork which extends through the greater portion of the chamber, the spaces between the checkerwork being left above and below the piers as "expansion spaces" being left above and below the piers. A partition extends downwards from the top of the checkerwork to the bottom of the chamber. A chimney stack having a damper communicating with the lower part of the chamber opposite the top of the stack, and "a blow-off means" is provided at the bottom of the stack. On the opposite side of the generator from the air blowers are provided, with means for forcing, if required, under pressure, jets of liquid fuel into the atomising fluid into the blast discharge pipe through a perforated ring.—R. L.

Apparatus for the Generation of —. B. E. Eldred, Assignor to Eldred Process Co., New York. U.S. Pat. 795,208, July 18, 1905.

The gas-producer is fed alternately with air and with the products from a lime kiln or with carbon dioxide

from a similar source with the aid of a gas producer. The products of combustion from the admission of air to the generator are discharged into a lime kiln, whilst the combustible gases produced during the passage of the chimney gases through the generator are collected, provision being made for either burning and superheating them.—R. L.

Gas Generation; Process for —. B. E. Eldred and C. Ellis, New York, Assignors to Eldred Process Co., New York. U.S. Pat. 795,257, July 18, 1905.

This process for the generation of combustible producer gas relatively low in hydrogen and nitrogen, consists in continuously passing through a flameless mass of ignited coal, a draught current composed of air and gaseous products from the calcination of lime, in such proportions as will serve to maintain the ignition of the gas generating fire whilst depressing its temperature below the clinkering point of the fuel. The combustible gas so produced is conveyed to the place of consumption without the addition of air, or part of it is returned to the lime kiln to be used for the calcination of lime.—R. L.

Gas Producer Apparatus. C. Ellis, Assignor to Eldred Process Co., New York. U.S. Pat. 795,258, July 18, 1905.

A gas engine receiving its gas supply from a generator is connected with the same by a return conduit. The products of combustion, or part of them, are reintroduced into the generator, passing on their way through an air-cooled radiator, where a great amount of their sensible heat is removed. Means are provided for mixing a predetermined quantity of air with these gases to form an endothermic mixture, capable of maintaining the producer at an effective gasifying temperature.—R. L.

FRENCH PATENTS.

Coal Dust; Methods of Firing with —. J. Mazodier. Fr. Pat. 352,012, March 3, 1905.

The coal dust is blown, by means of a fan, through a distributor into the fire-box. The distributor is of rectangular section and widens laterally but narrows vertically as it approaches the furnace, the mixture of coal dust and air entering the combustion chamber through a narrow horizontal slit. The amount of air delivered by the fan is purposely insufficient for the complete combustion of the coal, and the remainder enters beneath a grate placed in the furnace, below the level at which the coal dust is blown in. Any particles of coal that are too large to be kept in suspension by the current of air, fall on to this grate and burn there. The secondary air which enters below the grate becomes heated during its passage through the hot layer on the bars.—W. H. C.

Retort Ovens. Ifö Kaolin and Chamottefabrik Aktiebolag. Fr. Pat. 352,141, March 6, 1905.

CLAIM is made for the arrangement of the flues of the regenerator so that in successive courses the air flue passes between two waste gas flues. By means of suitable valves, a greater or less quantity of waste gas is made to pass beneath the water-pan in the ash-pit in order to regulate the amount of evaporation.—W. H. C.

Gas Producer. A. Fichet and R. Heurtey. Fr. Pat. 349,941, May 26, 1904.

INSIDE the upper portion of the producer is arranged an annular heater, through which the air supply is led on its way to the space beneath the fire grate. The fuel hopper is provided below with a downward cylindrical extension, the height of which can be regulated, the fuel being fed on to a distributing cone, the height of which may also be varied.—H. B.

Gas; Process for Obtaining Producer — from Vegetable Refuse from Oil Factories. O. Hentschel. Fr. Pat. 351,533, Feb. 15, 1905.

THE process claimed is specially designed for converting the combustible portions of the refuse from vegetable oil

factories, into a gas useful for motive purposes. This refuse under ordinary conditions is obtained in a form which does not permit of its direct use in a gas-generator. The principle of the patent is the conversion of this refuse into briquettes, either alone or after the addition of and mixture with some easily combustible substance.

— J. B. C. K.

Carburetted Air; Apparatus for the Production of —.
C. Philippe. Fr. Pat. 351,745, Feb. 23, 1905.

At the base of the apparatus is situated an air compressor, consisting of a drum-shaped chamber partly filled with water, in which rotate blades driven by a cord and falling weight. The air passes up into a chamber containing platinumised catalytic material, which becomes heated when gasoline is led into the chamber, and thus causes a rapid evaporation of the hydrocarbon; this chamber is constructed so that the air pursues a zig-zag course through it. Above the carburetting chamber is a storage space for the carburetted air, and the whole is surmounted by the gasoline tank, in which four spoon-like arms, mounted on a rotating shaft, dip successively into the gasoline, and deliver it into a cup, from which it flows down a tube into the carburetting chamber. The rotating shafts in the compressor and gasoline tank are geared together, so as to keep constant the ratio of air to gasoline.—H. B.

Producer for Briquettes; Suction —. Scheben and Krudewig. Fr. Pat. 351,788, Feb. 24, 1905.

THE briquettes are fed into the producer through a hopper, which extends downwards into the main combustion zone, the air and steam supply being admitted first into the annular space surrounding the hopper and then led down through the fuel to the gas-outlet, which is situated in the producer wall, a short distance above the fire-bars. A mechanical poker, consisting of a series of rods, mounted on a rotatable horizontal bar, is arranged below the fire-bars, and serves to clear the spaces between the latter of cinders. By means of a horizontal worm conveyor, extending along the base of the producer and actuated by an external handle, the cinders can be discharged periodically into a water-sealed receptacle, without interrupting the operation of the producer.—H. B.

Gas Generators; Impts. in —. H. G. Hills and C. H. Schill. Fr. Pat. 351,905, Feb. 28, 1905.

SEE Eng. Pat. 11,719 of 1904; this J., 1905, 538.—T. F. B.

Carbon Dioxide in Combustion Gases; Apparatus for the Determination of —. A. Schlatter and L. Deutsch. Fr. Pat. 351,442, Feb. 11, 1905. XXIII., page 904.

Filaments for Incandescence Electric Lamps and Process of Making them. Cie. Franç. pour l'Exploitation des Procédés Thomson-Houston. Fr. Pat. 349,857, April 15, 1904.

SEE Eng. Pat. 6959A of 1904; this J., 1905, 721.—T. F. B.

Electrodes for Arc Lamps. Comp. Générale d'Electricité. Fr. Pat. 349,928, May 20, 1904.

IN order to overcome the difficulties attending the use of conductors of the second class, in the construction of arc-lamp electrodes, the rods or the like, composed of refractory oxides (oxides of thorium, zirconium, aluminium, &c.), are provided with a thin coating of difficultly fusible metal (e.g., platinum or iridium) which does not oxidise or fuse at the temperature at which the electrode becomes a conductor. For example, cylindrical rods of refractory oxide, 2 mm. in diameter, are covered with a deposit of platinum weighing 0.01–0.02 gram. per centimetre. A layer of carbon may be superposed upon the metallic plating. Electrodes so constructed may be supported in sliding contacts, as in the case of carbon electrodes.—H. B.

Coke Ovens; Regenerative —. H. Koppers. Fr. Pat. 351,962, Jan. 30, 1905.

THE regenerator flues, placed beneath each oven, are

divided into two parts by the central arch, and by suite connections to the gas supply main, the air and waste gas flues can be used alternately for preheat the air or gas.—W. H. C.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

Toluene and Acetylene Tetrabromide; Reaction between— in presence of Aluminium Chloride. J. Lavi. Comptes rend., 1905, 141, 204–206.

THIS reaction (and no doubt other reactions with aluminium chloride is used) is rendered much a rapid and regular, and the yield is increased, by continuous agitation of the mixture during the reaction. 500 grms. of toluene and 100 grms. of the tetrabromide 130 grms. of aluminium chloride in powder must be used and the mixture heated to 90° C. till reaction ceases finally to 125° C. for a short while. The cooled mass treated with water and the liquid filtered with the aid of the pump; about 85 per cent. of the hydrocarbon formed is thus obtained pure, and the other 15 per cent. is obtained somewhat contaminated by tar, on evaporating the filtrate and washings. The products are two dimethylanthracenes, melting at 240° and 244°–5 C. respectively (a mixture of these melts at 225° C., the m.p. of the hydrocarbon obtained by Anschütz in studying this reaction), a small quantity of β -methylanthracene, benzene, xylene, and homologues, in addition to the excess of toluene. Considerable quantity of aluminium chloride must be used in this reaction, for it combines with the anthracene derivatives formed. The effect of the agitation is, doubt, due to the removal of the hydrochloric acid formed as the reaction progresses, and which if not removed limits the reaction by its tendency to produce the inactive one.—J. T. D.

[Petroleum] Crude Oil from Turkestan; New —. A. V. Ragosine. Chem. Rev. Fett.-u. Harz.-J., 1905, 12, 182–185.

IN a borehole recently sunk at Tchimon, to the east of Zakany in the Fergana valley, oil was struck at a depth of about 280 metres, and a yield of 150–170 tons of crude oil per diem has since been obtained by spontaneous flow and pumping. Another well close by reached the oil deposits at a depth of 276 metres, and five other wells are being sunk. The fresh crude oil has the sp. gr. 0.860–0.866, and is nearly black in colour, with a green fluorescence. It contains a large quantity of asphaltum, partly in solution, so that after standing for two days the sp. gr. increases to 0.875–0.883, which in turn may be raised to 0.895 by heating the oil in an open pan and blowing air through it. In this state the oil has a flashing point 75° C. (Pensky-Martens), and is suitable for locomotive fuel. Distilled with superheated steam, the crude oil furnished 14.5 per cent. of light spirit ("benzine"), sp. gr. 0.660–0.760; burning oil (sp. gr. 0.765–0.845), 31.4 per cent.; and a semi-solid residue of sp. gr. 0.924. The lightest fraction was found to contain hydrocarbons boiling below 17° C. (petroleum ether). Cracking experiments raised the proportion of burning oil to 46 per cent., and the residue was found to contain an average of 8 per cent. of paraffin. All the fractions of this Tchimon oil have a sp. gr. intermediate between those of American and Bakur oils, the values for the respective burning oils being:—Russian, 0.85; American, 0.081; Tchimon, 0.813. In addition to furnishing valuable light constituents, burning oil, fuel and paraffin, the oil will also yield vaseline.—C. S.

FRENCH PATENTS.

Ammonia; Process and Apparatus for Recovering — from [Coal] Gas. E. J. Duff. Fr. Pat. 352,121, March 8, 1905.

THE hot gas is led into a washer, in which it is caused

through a limited quantity of water, whereby it is freed from any solid impurities. The gas, thus charged to saturation with water vapour, then passes up a tower with perforated bricks, down which a constant stream of an absorbing liquid, such as a dilute solution of ammonium sulphate with a slight excess of sulphuric acid, trickles. From the top of this tower, the gas is led to the bottom of a second suitably packed tower, in which it meets descending streams of cold water to which it is to further absorb the ammonia. The water in the second tower is kept in circulation by pumping, or otherwise, in a direction contrary to that of the passage of the gas.

A special cooler is connected within the system of circulation to the second tower. The excess of water in the washings of the second tower is used to supply the first tower into which the gas is first led, and the excess in the washer is led to the tank connected to the bottom of the tower, containing the acidulated solution, after being freed from suspended particles in a settling vessel. —E. S.

and Analogous Substances; Rectifying — J. Pollet. Fr. Pat. 351,519, Feb. 15, 1905.

The gases are caused to circulate around a vessel containing the oil to be treated, and the vapours thereby formed are passed through a superimposed column with baffles, which arrest the heavy fractions and enable them to fall back into the oil vessel, whilst the lighter fractions escape to a condensing coil.—C. S.

III.—COLOURING MATTERS AND DYE-STUFFS.

Fast to Alkalis; Triphenylmethane — L. E. Rev. Gén. des Mat. Col., 1905, 9, 223—224.

ETHYLDIAMINODIPHENYLCARBINOL hydrochloride, condensed with *o*-methoxyaniline, gives the leuco-product of a bluish-violet dyestuff. On replacing the hydrogen in this by hydrogen, by the diazo reaction, the product, a dyestuff is formed which, when used to dye wool and silk, gives a bluish-green shade. By substituting *o*-toluidine for *o*-methoxyaniline in the above reaction, the leuco-base of a reddish-violet dyestuff is obtained. This, when reduced and oxidised, yields a dyestuff which dyes silk and wool in bluish-blue shades. It would thus appear that the position of the hydroxyl- or other group on the *m*-position to the carbon atom than it is by the position which this group occupies in the molecule. —this J., 1904, 603.)

In support of this view, E. Justin-Müller points out that the dyestuff (Fast Green, blue shade), prepared by the process of Pat. 1885 (this J., 1886, 661) and, therefore, the discovery (in 1888) of Patent Blue, which is the latter dyestuff in constitution, but contains in its molecule an $N(CH_2.C_6H_4.SO_3H)_2$ group, of the hydroxyl-group present in Patent Blue, in the *m*-position to the central carbon atom, also that dyestuff in its properties of shade and fastness to alkalis.—E. B.

ENGLISH PATENTS.

[Azo]; Manufacture of New Tetrazo — J. Newton, London. From Farbenfabr. vorm. F. & C. Bayer und Co., Elberfeld, Germany. Eng. Pat. 347,376 of 1904; this J., 1905, 329.—T. F. B.

for Wool; Manufacture of Azo — O. J. Newton, London. From Society of Chemical Industry, Basle, Switzerland. Eng. Pat. 82, Jan. 2, 1905.

Pat. 351,125 of 1905; this J., 1905, 840.—T. F. B.

Dyestuffs; [Electrolytic] Manufacture of Leuco-galloyaniline — J. G. W. Johnson, London. From the Dyeworks, formerly L. Durand, Huguenin and Co., Basle, Switzerland. Eng. Pat. 7835, April 12, 1905.

THE manufacture of leuco-galloyaniline dyestuff-compounds, which is effected, according to Eng. Pat. 21,445 of 1898, 4551 of 1902, and 3497 of 1905 (this J., 1899, 827; 1902, 609; 1905, 494), by means of chemical reducing agents, may be advantageously accomplished by electrolysis. For example, 30 grms. of Gallonine Blue G M (Eng. Pat. 2941 of 1889; this J., 1889, 981) are suspended in 600 c.c. of water, acidified with 33 grms. of concentrated hydrochloric acid. The mixture is placed in the cathode compartment of a cell divided into two compartments by a diaphragm, the cathode consisting of a sheet of platinum. The anode compartment contains hydrochloric acid and a carbon anode. The reduction is effected at a temperature of 70–80 °C., with a current density of 1–1½ ampères per sq. dem. of cathode surface, the reaction being complete when the whole of the dyestuff has passed into solution and the original violet colour has changed to a brownish-green. The leuco product is obtained by salting out. Other leuco-galloyanilines are similarly prepared; in some cases being sparingly soluble, they may be separated by filtration. —E. B.

Indigo; Production of — J. Y. Johnson, London. From the Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. Eng. Pat. 12,854, June 21, 1905.

WHEN air is passed into an alkaline solution of a leuco-compound of indigo, the indigo tends to separate in a finely crystalline condition. It can be obtained in a state of fine division, more suitable for use in dyeing and printing, by oxidising in presence of an alkali salt of a saturated or unsaturated fatty acid, or resin acid. Instead of air other suitable oxidising agents may be used. For example, 100 parts of indoxyllic acid are dissolved in 2500 parts of water and the necessary amount of sodium hydroxide, 10 parts of soft soap added, and a current of air passed through the boiling liquid.—E. F.

UNITED STATES PATENT.

Dyestuff, Tetrazo; Bisulphite Compound of a —, and *Process of Making same*. A. Otto, Assignor to Farbwerke, vorm. Meister, Lucius and Brüning, Höchst-on-the-Maine, Germany. U.S. Pat. 795,958, July 18, 1905.

THE dyestuff produced from 1 mol. of *o*-*o*-tetrazophenol-*p*-sulphonic acid and 2 mols. of β -naphthol is dissolved in a solution of sodium bisulphite, sufficient mineral acid added to just produce an acid reaction, and the mixture evaporated to dryness. The new product is stable and soluble in water. The original dyestuff separates on heating the aqueous solution.—E. F.

FRENCH PATENT.

Dyestuffs Derived from Dyestuffs of the Oxazine Series; Production of New —, Manuf. de Mat. Col. Ancien. L. Durand, Huguenin et Cie. Fr. Pat. 351,658, Feb. 13, 1905.

SEE Eng. Pat. 3497 of 1905; this J., 1905, 494.—T. F. B.

GERMAN PATENTS.

[Anthracene Dyestuffs] Anthraquinone and its Derivatives; Process of Preparing Aryl Ethers of —, Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 158,531, May 12, 1903.

ARYL ethers of anthraquinone and its derivatives are obtained by the action of monohydric phenols, either in the form of their alkali salts, or in alkaline solution, on negatively substituted anthraquinone derivatives. Thus the phenyl ether of erythrohydroxyanthraquinone is obtained from anthraquinone- α -monosulphonic acid, or from α -mononitro- or α -monobromoanthraquinone; the diphenyl and di- β -naphthyl ethers of anthraquinone and the phenyl ether of β -hydroxyanthraquinone can also be obtained by this method.—T. F. B.

[*Arthraena* Dye-stuffs] *o*-Monobromoa-minoanthraquinones. *Method of Preparing* —. Farbentab. vorm. F. Bayer und Co. Ger. Pat. 160,169, Jan. 8, 1904.

By brominating *o*-aminoanthraquinone or one of its substitution products with just the theoretical quantity of bromine, monobromo derivatives are produced. These derivatives are of value for the production of the dyestuffs described in Fr. Pat. 349,606 of 1904 (this J., 1905, 726). — T. F. B.

Dye-stuffs [1,2-]; *Process of Preparing Blue Amino-mono-* —. Farbwerke vorm. Meister, Lucius und Brünig. Ger. Pat. 160,281, Oct. 21, 1903.

CHLOROCROMOTROPE acid, obtained by treating 1,8-dihydroxynaphthalene-3,6-disulphonic acid with hypochlorous acid or a hypochlorite, is combined with the diazo derivative of *p*-nitraniline, chloro-*p*-nitraniline, or 2,5-nitro-aminohydroquinone dimethyl ether. The nitro-azo dyestuffs thus produced are reduced to amino-azo dyestuffs, which dye wool from acid baths in blue shades. Other monosubstitution derivatives of chromotrope acid are stated to give dyestuffs of little technical value. — T. F. B.

Dye-stuffs; *Process of Preparing Red Sulphide* —. Farbwerke vorm. Meister, Lucius und Brünig. Ger. Pat. 160,395, Feb. 10, 1904.

RED sulphide dyestuffs are obtained by heating resorcinol with sulphur and a formyl derivative of an aromatic base to a high temperature. For example, 2 parts of form-aniline, 4 parts of resorcinol, about 1 part of glycerin and 4 parts of sulphur are heated for five hours at 180–185° C.; the product dyes unmercerized cotton reddish shades from sodium sulphide baths. Formyl-*o*- or *p*-toluidine or formyl benzidine are utilised in a similar manner. The shades produced by the dyestuffs can be modified by altering the proportions of the materials employed, or by varying the temperature. — T. F. B.

p-Nitro-*o*-chloro-*o*-cresol ($\text{OH} : \text{CH}_3 : \text{NO}_2 : (\text{Cl} = 1 : 2 : 4 : 6)$). *Method of Preparing* —. F. Raschig. Ger. Pat. 160,304, Dec. 20, 1903.

ONE HUNDRED kilos. of *o*-cresol are heated with an equal weight of sulphuric acid (monohydrate) for several hours at about 100° C. The product is diluted with 800 litres of water and chlorine is passed in until an increase in weight of 70 kilos. is reached; the product is *o*-chloro-*o*-cresol-*p*-sulphonic acid. After filtering off the small amount of dichlorocresol produced, the sulphonic acid group is replaced by a nitro group by the addition of 80 kilos. of sodium nitrate. *p*-Nitro-*o*-chloro-*o*-cresol ($\text{OH} : \text{CH}_3 : \text{NO}_2 : \text{Cl} = 1 : 2 : 4 : 6$) is thus obtained. This substance is said to be of value in the preparation of sulphide dyestuffs. — T. F. B.

Trihydroxyphenylrosinduline [1,2-*ino* Dye-stuff]; *Process of Preparing* —. Kalle und Co. Ger. Pat. 160,789, April 12, 1904. Addition to Ger. Pat. 158,077, Dec. 4, 1902 (see this J., 1905, 614).

TRIHYDROXYPHENYLOSINDULINE is said to be obtained in a very pure condition by heating alcoholic solutions of substances which can produce 1,4-naphthylenediamine with hydrochloric acid and *p*-aminophenol, *m*- or *p*-nitraniline. (See also Ger. Pat. 158,100; this J., 1905, 614.) — T. F. B.

Dye-stuff; *Process of Preparing a Red-violet Sulphide* —. Kalle und Co. Ger. Pat. 160,790, April 12, 1904. Addition to Ger. Pat. 152,373, June 12, 1903.

THE trihydroxyphenylrosinduline used for the production of sulphide dyestuffs according to the original patent (this J., 1905, 614) is replaced by the product obtained according to Ger. Pat. 160,789 (see preceding abstract). The resulting dyestuffs are said to produce purer and redder shades than those formerly described. — T. F. B.

Hydroxyphenylrosindulines [1,2-*ino* Dye-stuffs]; *Method of Preparing* —. Kalle und Co. Ger. Pat. 160,815, April 15, 1904. Addition to Ger. Pat. 158,077, Dec. 4, 1902 (see this J., 1905, 614).

FURTHER modifications are introduced into the processes of Ger. Pats. 158,077, 158,101 (this J., 1905, 614), and 160,789 (above), by the substitution for benzeneazo-

naphthylamine of benzeneazomonoaryl-*o*-naphthyl or of monoaryl-1,4-diaminonaphthalene. The resulting dyestuffs are stated to produce purer and bluer shades than those mentioned above. — T. F. B.

Dye-stuff; *Process of Preparing a Violet Sulphide* —. Kalle und Co. Ger. Pat. 160,816, April 15, 1904. Addition to Ger. Pat. 152,373, June 12, 1903.

THE hydroxyphenylrosindulines obtained according to Ger. Pat. 160,815 (preceding this), are used for the production of sulphide dyestuffs, according to the process described in Ger. Pat. 152,373 (this J., 1905, 614). The shades obtained on cotton with these dyestuffs are purer and bluer than those produced by the dyestuffs of the original patent, and are also faster to washing. — T. F. B.

p-Aminophenylsulphonic Acid ($\text{OH} : \text{NH}_2 : \text{SO}_3\text{H} = 1 : 4$). *Process of Preparing* —. Act.-Ges. f. Anilin. Ger. Pat. 160,170, Aug. 4, 1904.

p-AMINOPHENOL-*m*-SULPHONIC acid, formerly obtained by heating mononitro-acetylmetanilic acid with sodium hydroxide and reducing the product, can be prepared by diazotizing *p*-phenylenediaminemonosulphonic acid with one equivalent of nitrous acid, and boiling the resulting solution. — T. F. B.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

Cellulose; *Solubility of* — in *Thiocyanates*. XIX., page 901.

ENGLISH PATENTS.

Nitrocellulose Solutions for Use in the Treatment of —. P. Kraus, Ilkley, and The Bradford Dyers' Association Ltd., Bradford. Eng. Pat. 18,742, Aug. 10, 1904.

SUITABLE solutions of nitrocellulose are a desideratum for application to fabrics in order to give them a "Schreiner finish." Hitherto the use of collodion solutions in amyl acetate has been tried. Collodion solutions are unsatisfactory as the ether-alcohol vapours evolved are explosive and unhealthy. Amyl acetate clings to the fabric, even after long drying, causing a disagreeable odour. The patentees use a solution of nitrocellulose in amyl formate. This leaves no objectionable residue behind, its b. pt. being about 15° C. lower than that of the acetate. Also amyl formate solutions are more fluid than amyl acetate solutions of the same strength. A 5 per cent. solution is suitable, and is best applied in succession, by spraying or otherwise, the solvent being evaporated after each application. The resulting finish should not form a complete skin, but should be sufficient to fix the lustre finish produced. — E. F.

Threads from Collodion; *Apparatus for Producing and Recovering the Solvents Employed*. — Denia, Reims, France. Eng. Pat. 4534, March 4, 1905. Under Int. Conv., March 5, 1904.

SEE Fr. Pat. 341,173 of 1904; this J., 1904, 864. — F. B.

Retting and Washing Textile Fibres; *Method of* —. A. J. Boulton, London. From E. Poisson, Aubagne, France. Eng. Pat. 16,313, July 23, 1904.

SEE Fr. Pat. 338,941 of 1903; this J., 1904, 982. — F. B.

Ramie and the like; *Method and Apparatus for Treating* [Decorticating] —. C. Pissard, Villetaneuse, France. Eng. Pat. 20,757, Sept. 27, 1904.

RAMIE or other similar fibre is steeped in water for several days, and then heated in a dilute alkali solution until the gums are thoroughly softened. The fibre is now pressed out in a thin layer on an inclined plane, and subjected to the action of a number of jets of water, when it is found that all the gum and pellicle is removed from the fibre. A suitable apparatus for the latter process consists of a supporting bed of perforated sheet metal or woven mesh, bent to form a roof-shaped structure, the inverted V section; the fibre is laid transversely across the apex of this support. Above it is a tank or receptacle for water of suitable form, the bottom being perforated

shaped similarly to the fibre support. Both the port and the water tank may be movable longitudinally, and either one or the other may be capable of vertical movement.—T. F. B.

Cotton Waste; Removing Grease from — J. W. Itchell, Rawtenstall. Eng. Pat. 17,339, Aug. 9, 1904.

Cotton waste, in a greasy condition, is placed in an acid apparatus, where it is simultaneously freed from grease, &c., and prepared for bleaching by the following process which is performed without the waste being removed from the apparatus:—(1) Treatment with a solvent, such as "benzine"; (2) steaming, for the purpose of evaporating and expelling from the cotton waste the solvent still remaining in it after as much as possible of it has been recovered by draining; (3) treatment with neutral acid; (4) boiling with an alkali-lye; and (5) rinsing with water.—E. B.

Woolen Rags, Wool and other Animal Fibres; Method and Means for Removing [Carbonising] Vegetable Impurities from — S. Roberts, Liversedge, and J. Crossley, Mirfield. Eng. Pat. 15,729, July 15, 1904.

The object of reducing the duration of treatment and of acid used, and of dispensing with the operation of neutralising the acid left in the treated materials, in the process of carbonising the cotton and other vegetable fibres contained in loose wool and woollen fabrics, the fibres are treated with hydrochloric acid, in a more dilute solution than that in which this acid has hitherto been used for the purpose, while they are moved about intermittently to bring the acid more intimately into contact with them. In the case of loose wool, an apparatus of the type of McNaught's wool-washing machine, is used in effecting the saturation with acid, the liquor being agitated by means of agitating forks being constructed of wood, such as wood, which are not readily attacked by dilute acids. The fibres are afterwards passed between squeezing rollers, to remove the excess of the acid solution, and are then deposited upon a revolving apron or fed into a tube, upon or in which they are dried by hot air. Finally, they are conveyed to a drying-machine, by means of which the charred vegetable fibres are separated in the form of dust. The apparatus is so constructed and arranged that the whole process described, after the feeding of the fibres into the hopper of the machine, in which the dilute acid is applied, may be continuously and automatically performed.—E. B.

Woolen Materials; Apparatus for Treating [Felling] — C. Marks, London. From G. Goldman, Baltimore, Maryland, U.S.A. Eng. Pat. 27,533, Dec. 16, 1904.

Woolen materials, preferably in the form of sheets, into which either liquid or dry binding materials are introduced, are conveyed between endless bands over a hollow, steam-heated table, upon which they are pressed by means of steam-heated rollers. The fibres are thus held together by the combined action of moisture, heat, and pressure. The lower of the two endless bands is composed of absorbent material, and is damped with steam when dry binding materials are employed. (See Eng. Pat. 1904, 544).—E. B.

Woolen Materials; Apparatus for Dyeing and Bleaching — T. de Naeyer, Alost, Belgium. Eng. Pat. 17,333, Dec. 31, 1904. Under Int. Conv., Jan. 30, 1905.

Materials to be dyed are placed in a rotating, cubical vat provided at its top and bottom with air-escape apertures for liquor pipes, and false walls, mainly in position by springs, screws, &c., between which the materials are compressed. The dye, &c., liquors are drawn from a boiler to the top of the vat, and after passing through the materials are returned to the top of the vat. The direction of their flow through the materials is reversed by inverting the vat. A second boiler is directly connected with the vat, to receive the liquor from this, while the first boiler is being charged with liquor or with water for rinsing purposes, &c. Three or more vats and as many boilers, with a common boiler in addition, may be connected together, the necessary liquor-pipes and pumps, to enable

the materials to be operated upon by the liquor contained in any of the boilers.—E. B.

Dyeing Yarns in Cops or Pies; Apparatus for — J. O. O'Brien, Manchester. From H. L. Hüller, Paris. Eng. Pat. 10,448, May 18, 1905.

Fireproofing Textile Fabrics and the like; Compounds and Processes for — W. M. Walker, London. Eng. Pat. 4971, March 9, 1905.

AMMONIUM sulphate solution is mixed with ordinary starch or size, and the mixture used for fireproofing textiles for various purposes. Borax may be added to the solution. For fireproofing canvas, a solution of 2 lb. of ammonium sulphate in 1 gall. of water is mixed with 8 lb. of size. Reference has been directed, in pursuance of Sec. 1, Sub-sec. 6 of the Patents Act, 1902, to Eng. Pats. 1657 of 1872; 1458 of 1900 (this J., 1900, 904) and 16,372 of 1902 (this J., 1903, 862).—T. F. B.

Fabrics; Apparatus for Treating Tubular — with Liquid or Semi-liquid Compositions. W. R. Smith, Buffalo, New York, U.S.A. Eng. Pat. 26,005, Nov. 29, 1904.

A TUBULAR fabric, such as woven hose-piping for conducting water, is supported upon a hollow mandrel which communicates with a vessel containing a viscous, waterproofing composition, such as a solution of india-rubber. The mandrel has openings in it through which the solution is forced outwards into and through the fabric, which, along with the mandrel and the solution, is heated during the operation. Besides the means for accomplishing this, devices are described and claimed for the application of a rubbing or sliding pressure to the outer surface, and for the lubrication with a suitable preparation, e.g., one containing talc, of the inner surface of the waterproofed fabric, while this is on an extension of the mandrel. This extension consists of a tube of smaller diameter than the mandrel, with its outer end closed, thus constituting a heated drying-chamber upon which the fabric is dried and finished.—E. B.

Cork; Treatment of — for the Manufacture of Cork Fabrics. R. A. Grimoire-Sanson, Paris. Eng. Pat. 14,839, July 1, 1904. Under Int. Conv., Jan. 15, 1904.

CORK, in very thin sheets, is heated under pressure in a mixture of benzene and carbon bisulphide (or essence of turpentine) containing also glycerin, Para rubber, and hydrochloric acid, and is then applied to cleansed canvas, leather, or other fabrics by means of an agglutinant, obtained by macerating caoutchouc in a mixture of petroleum ether and acetone. The coated fabric is then rolled and stoved.—E. S.

UNITED STATES PATENTS.

Cellulose; Threads of Artificial [Silk] from Solutions of — R. Linkmeyer, Herford, Germany. U.S. Pat. 795,526, July 25, 1905.

Dyeing Machine. R. P. Smith, Assignor to G. E. Drim, Philadelphia, Pa., U.S.A. U.S. Pat. 794,560, July 11, 1905.

THE combination is claimed of a dye-tank to contain the liquors employed; a perforated receptacle for the materials to be dyed, semi-circular in cross-section provided with a hinged bottom, and movable into and out of the tank; a frame which can be lowered upon or raised from the top of the tank; an agitator mounted in the frame and adapted to be operated on a horizontal axis for the purpose of agitating the materials to be dyed; and means for driving the agitator.—E. B.

FRENCH PATENTS.

Papier-mâché Threads; Manufacture of — W. Müller. Fr. Pat. 351,902, Feb. 28, 1905. XIX., page 901.

Cellulose Threads (Artificial Silk) ; Process for Increasing the Lustre of —. R. Linkmeyer and M. Pollak. Fr. Pat. 350,889, Jan. 20, 1905.

THREADS of artificial silk, especially such as are produced from ammoniacal solutions of cellulose, are said to be rendered more lustrous, when they are stretched to the extent of $\frac{1}{2}$ of their length, before and during the operation of drying, in the course of the process of their manufacture.—E. B.

Wool-washing Machines ; Impts. in —. W. McNaught. Fr. Pat. 351,629, Feb. 20, 1905. Under Int. Conv., Oct. 31, 1904.

Two sets of fork-bearing frames, arranged side by side, are used in the apparatus which forms the subject of this invention. One set has forks at intervals throughout its length; the other is furnished with them only in that part which operates above the delivery end of the apparatus. Both sets are actuated horizontally and vertically in such a way as to cause the loose wool contained in the washing tank, into which the forks descend, to be carried forward from one end of the tank to the other, the wool being moved in an intermittent manner by the first set, when acting alone, and in a continuous manner by the two sets, when these operate together. To collect the dirt, &c., present in the wool, a receptacle is placed below a perforated, inclined plate or board at the exit end of the apparatus. The bottom of the receptacle slopes downwards to one side where a sluice is provided for the removal of the dirt, &c. The receptacle is divided by vertical partitions into a number of compartments, for the purpose of preventing the water in it from moving about and entangling the wool upon the inclined plate.—E. B.

Textile Fibres (Linen, Ramie, &c.) ; Process for Bleaching and Rendering Lustrous —. A. Haack. Fr. Pat. 351,088, Jan. 28, 1905.

TEXTILE fibres, such as linen, hemp and ramie, after being bleached by a process which consists in boiling with a solution of either sodium "sulphuricinate" or sodium resinate, and then treating with a mixture of sodium carbonate and sodium hypochlorite, are placed in an autoclave and treated, for about two hours, under a pressure of 2–8 or more atmospheres, with a mixture of waxes and oils, &c., such as Japan wax, stearin, paraffin wax, spermaceti, castor oil, and olive oil, to which a little camphor may be added, the whole being "diluted" with alcohol. The excess of oil, &c., is then removed from the fibres by boiling them for about 15 minutes in a dilute solution of sodium carbonate and soap.—E. B.

Chlorine ; Process for Increasing the Chemical Action of —. B. Margulies and Co. Fr. Pat. 352,196, March 8, 1905. VII., page 892.

Mercurising ; Process and Apparatus for —. W. Mather, J. Hübner and W. J. Pope. Fr. Pat. 352,233, March 10, 1905. Under Int. Conv., March 16, 1904.

SEE Eng. Pat. 6383 of 1904; this J., 1905, 272.—T. F. B.

Silks, and Dyeing Textile Materials in General ; Apparatus for Charging —. C. Lammpp and Co. Fr. Pat. 349,891, May 5, 1904.

THE apparatus forming the subject of this invention consists of an over-driven hydro-extractor, characterized by a special form of construction of cage and cage-bearing mechanism. The latter is a hollow cone or bell, at the upper part of which the cage is balanced, a cushion of air between the two preventing the access of dye, &c. liquors to the cone. When the apparatus is in use, &c., liquors are conveyed from a well into the cage, &c. this is completely full, the excess running through an overflow pipe back to the well. The cage is then set in rotation and the materials contained in it, dyed, &c.—E. B.

Yarns in the form of Cops or on Bobbins ; Dyeing —. H. L'Huillier. Fr. Pat. 350,981, Jan. 24, 1905.

THE cops, &c., to be dyed are placed on perforated tubes affixed to pipes laid transversely across and attached to a main pipe, which communicates with a conduit at the bottom of a dye-tank. The latter is closed by means of an air-tight cover during the operation of dyeing. The dye-liquors, as also the water used in rinsing, are drawn by a suction apparatus from a storage-vessel, through the conduit, the system of pipes, and the cops, into the tank. Air is then admitted into the tank, causing the liquor to flow back to the storage-vessel, the passage of the liquor through the cops being repeated in this manner as often as is necessary. The cops, &c., are kept in position on the tubes by means of bands of metal, &c., resting upon the tubes.—E. B.

Dyeing Skins ; Apparatus for —. B. Oriol. Fr. Pat. 351,717, Feb. 23, 1905.

Fig. 2

hanks are hung from special supports *c, n, d* (Fig. 1). The revolving of four parallel bent rods fixed between two supports. These supports revolve several times in one revolution, then make several partial revolutions, revolve in the other direction, and so on, to ensure even dyeing. The movements are controlled by a lever *P* (Fig. 2). A rod *Q* which moves in a groove on the revolving support. The lever *P* is connected up with the rod *T*. The rod *T* has two forks at *V* and *X*. These forks guide the revolving on the pulleys *D, C* and *E*. The movement of these pulleys determine the direction of movement of the shaft *B*, which, in turn, controls the movement of the hank-supports. There is an arrangement for lifting the individual hanks from the dye-bath. A hank support can be separately thrown out of action.

VII.—ACIDS, ALKALIS, AND SALTS.

Sulphuric Acid Manufacture; Contact Process of — R. Lucas. Z. Elektrochem. 1905, 11, 457—461.

THE author has repeated and extended the experiments of Bedländer and von Köppen (this J., 1903, 1128). H.

finds that the absorption of the gases at temperatures above 600° C. which these authors mentioned, does not occur when the platinum used is absolutely free from iridium; and he has modified some of the details of their apparatus so as to make the results of the measurements trustworthy within narrower limits. The experiments were conducted in both directions, the gaseous mixture being in some instances cooled from the temperature of experiment to 400° C., and in others heated from 400° C. to the required temperature. The results of the two series showed satisfactory agreement, but the attainment of equilibrium after dissociation through rise of temperature was much slower than after re-combination through its fall. Detailed examples are given of the mode of calculating k from the composition of the original gaseous mixture, and the observed temperatures and alterations of pressure. The results are here tabulated:—

Composition of Gases.			Temp. C.	Value of k .
SO ₂ .	O ₂ .	N ₂ .		
65.33	32.66	2.00	585	9.465×10^{-6}
			680	2.214×10^{-4}
			787	1.310×10^{-3}
			870	4.180×10^{-3}
57.00	42.00	1.00	730	6.743×10^{-4}
			820	3.555×10^{-3}
66.66	33.33	—	565	8.870×10^{-6}
			615	1.560×10^{-5}
			680	1.110×10^{-4}
28.15	15.05	56.80	725	2.520×10^{-4}
			820	1.640×10^{-3}
39.00	61.00	—	665	1.766×10^{-4}
			680	2.050×10^{-4}
			705	2.590×10^{-4}
			798	3.556×10^{-3}

The three determinations at 680° C. for different mixtures, 2.214, 1.11, and 2.05×10^{-4} , agree within satisfactory limits, and show that k is independent of the composition of the original gaseous mixture. The value of Q , the molecular heat of formation of gaseous sulphur trioxide, calculated from the figures for each of the five mixtures, comes out as 20875, 17950, 23700, 19320, 21260 calories respectively. The corresponding values from Knietzsch's figures between 18620 and 27125 cal., and from Bodländer and Köppen's between 25455 and 30280. The most probable value calculated by least squares from all these results is 18840 cal., and if from this the values of k for different temperatures be calculated, the results are as follows:—

Temp. °C.	k		k	
	Knietzsch.	B. & K.	Lucas.	
500	2.026×10^{-6}	1.92×10^{-6}	1.646×10^{-6}	
600	6.485×10^{-5}	8.56×10^{-5}	2.720×10^{-5}	
700	5.810×10^{-4}	—	2.525×10^{-4}	
800	3.716×10^{-3}	—	1.54×10^{-3}	

The author gives also a table similar to that of Bodländer and Köppen (*loc. cit.* 1129), showing the temperatures at which a definite percentage of complete conversion occurs for different mixtures:—

Composition of original mixture.		Yield of SO ₂ .					
SO ₂ .	O ₂ .	98 p.c.	96 p.c.	94 p.c.	90 p.c.	80 p.c.	60 p.c.
66.66	33.33	415	470	503	665	650	768
11.69	5.85	—	415	448	490	565	673
10.0	8.04	445	497	522	564	612	683
7.0	10.0	467	503	532	570	637	730
6.0	13.23	477	517	545	585	655	750
2.0	18.45	490	533	565	604	675	785

For the mixture, 7 per cent. of sulphur dioxide, 10 per cent. of oxygen, and 83 per cent. of nitrogen, the yields given by the manometric process in the hands of the author are

somewhat higher than those published by Knietzsch. The addition of air to the "ideal" burner gas increases the yield, but lowers the speed of reaction, and the most advantageous mixture must thus be a matter of compromise. —J. T. D.

Chlorides Anhydrous: Method of Preparing —

Matignon and F. Bourion. Chem.-Zeit., 1902, 29, 780—782.

It is found that by substituting sulphur for carbon in the usual method of chlorinating oxides, a considerable lowering of the temperature of reaction takes place.

For the preparation of chlorides from oxides the following general method may be used. A stream of chlorine after drying over phosphorus pentoxide, is passed into a vessel containing sulphur chloride. The chlorine is thereby saturated with the reducing vapour, and allowed to enter the tube of oxide which is maintained at the requisite temperature (about 350°—400° C., vary with different oxides). It is advisable to use a tube of Jena glass for this purpose. Condensing apparatus connected to the opposite end of this tube, and arrangements are made for the escape of the gases which evolved.

If the resulting chloride is volatile, great care must be taken not to use excess of sulphur chloride, or an impure product will result. Usually, however, the condensing apparatus is maintained at 80° C., and the volatile sulphur chloride passes off. In this way the following oxides have been converted into chlorides quite readily, silica, alumina, thoria, praseodymium and neodymium oxides, samarium oxide, vanadic acid, tungstic acid, boric acid, chromium and iron oxides. Calcium, barium and samarium sulphates also give chlorides when subjected to this treatment. —B. J. S.

Silicates of Potassium and other Bases: Method of Making — Applied to Oxide of Zinc. A. Dubé. Comptes rend., 1905, 141, 254—256.

A QUANTITY of potassium fluoride is fused in a platinum crucible. Silica and precipitated oxide of zinc are then added, and the crucible cooled. The contents are then melted with some potassium chloride, and kept at a heat for three days. The potassium-zinc silicates are separated from the mixture by the use of a hot solution of sodium-mercuric iodide. The first silicate $K_2O, 0.6ZnO, 4SiO_2$, has a sp. gr. of 3.68. The second product, $8K_2O, 9ZnO, 17SiO_2$, has a sp. gr. of 2.96. —F.

Deacon Chlorine Process: Function of the Catalyst. — M. G. Levi and V. Bettoni. Gaz. chim. ital., 1905, 35, 320—342.

IN the authors' experiments a regular current of hydrochloric acid gas mixed with the quantity of air required according to the equation: $2HCl + O = H_2O + Cl_2$, was led through a tube of refractory glass containing pieces of pumice impregnated with cupric chloride. The outflowing gases were passed through a washing bottle and then through a standardised alkaline solution of arsenious acid, the relative proportions of hydrochloric acid and chlorine being calculated, after titrating the excess of arsenious acid with iodine solution, and the hydrochloric acid with silver nitrate solution. The experiments were limited to temperatures of up to about 400° C. Up to about 300° C. the yields of chlorine were very small. At 300° C., at the most, only 7—8 per cent. of the hydrochloric acid was decomposed, but at 400° C., the yield (3 per cent.) approached that attained in practice. The yield was lowered by increasing the velocity of the gas much. At the end of the experiment, in every case only cupric chloride was present in the pumice, and cuprous chloride or basic cupric chloride, $Cu_2O \cdot CuCl_2$, could be detected. The method of preparing the pieces of pumice was found to have considerable influence on the results; for example, if they are dried for too long a period or at a high temperature, after impregnation with cupric chloride, they become quite inactive. In the experiments, the results of which are quoted above, the pumice was prepared by boiling it for several hours in aqua regia, washing, drying, boiling several times

ion for about two hours in a 50 percent. solution of chloride, allowing to stand over-night in the tube, and drying at 100—150° C. Pumice impregnated with cuprous chloride or basic cupric chloride does not cause any decomposition of hydrochloric acid at 400° C., nor could any transformation of basic chloride into cupric chloride by dry hydrochloric acid be observed under the conditions of the experiment.

Since not only cupric chloride, but also copper, nickel, manganese and magnesium chlorides, even strongly heated pumice alone, are capable of imposing a mixture of hydrochloric acid and air, reduction of chlorine, provided a suitable temperature is chosen, the authors conclude that the catalytic effect of all these substances is due solely to their power of absorbing moisture. The facts known with regard to the Deacon process all serve to corroborate this view. Substances capable of acting as catalysers all possess the power of absorbing moisture. At lower temperatures, the effects of chlorine are diminished up to a certain limit in the presence of water. The catalyser is completely exhausted at the end of the process. The decomposition of hydrochloric acid proceeds under such conditions as a compound of its constituents with the copper is excluded. Finally, from thermochemical data, the decomposition of gaseous hydrochloric acid is to be expected, because in the system $2\text{HCl} + \text{O}$, the tendency to the formation of water, and this tendency is, of course, favoured by the presence of substances capable of absorbing water.—A. S.

Chlorides and Bromates; Volumetric Determination of—. M. Scholtz. XXIII., page 904.

ENGLISH PATENT.

and Alkaline Earth Carbonates; Manufacture of—, and Apparatus therefor. A. P. Polunovsky, of Antwerp, Belgium. Eng. Pat. 18,899, Sept. 1, 1904.

A sulphate, obtained from the chloride in the usual manner, mixed with coal or other reducing agent, and heated to obtain the sulphide, which is dissolved in water or in ammonia solution, or in alcohol. The solution is treated with carbon dioxide in an upright jacketed vessel, provided with a mechanical stirrer, and connected at the bottom by a valve to a second cylinder, in which the liquid is forced by pressure

from the carbon dioxide, through a pipe leading to a second cylinder, to return to the upper cylinder for re-treatment, whilst the sodium carbonate or bicarbonate precipitating upon the filter is removed through a suitable aperture. The hydrogen sulphide produced in the process is treated with sulphur dioxide to obtain sulphur.—E. S.

UNITED STATES PATENTS.

Aluminium Compounds; Process of Making—. T. R. Keogh, Hamilton, Canada. U.S. Pat. 794,413, July 11, 1905.

ALUMINUM materials are acted upon by sulphur gas, to form aluminium sulphate; this is mixed with sodium chloride and carbon, and the mixture is heated in a current of steam; the hydrochloric acid gas evolved is collected, and the residual mixture, containing alumina, sodium sulphate and carbon, is heated to reduce the sodium sulphate to sulphide. The product is then heated in the presence of steam and air to form sodium aluminate, sulphurous acid being evolved. From the sodium aluminate, hydrated alumina and sodium carbonate are obtained. (Compare U.S. Pat. 744,765 of 1903, and Eng. Pat. 23,918 and 23,919 of 1902, and 2655 of Feb. 3, 1904; this J., 1903, 1347, and 1904, 370, 186, and 1088 respectively.)—E. S.

Sodium Ferrocyanide; Process for Obtaining—from a Solution of Calcium Ferrocyanide. Administration des Mines de Bouxwiller. Fr. Pat. 352,246, Jan. 19, 1905.

IN the process for obtaining sodium ferrocyanide from a solution containing calcium ferrocyanide and sodium chloride, described in Fr. Pat. 339,996, of Jan. 28, 1904 (this J., 1904, 714), the solution, according to the present invention, is concentrated by heat at atmospheric pressure, until the double salt, sodium-calcium ferrocyanide, begins to form; the concentration is then continued in a vacuum, at a lower temperature, when the double salt already formed redissolves, and a concentrated solution is obtained, which, on cooling, gives sodium ferrocyanide in large crystals. The mother liquor is then further concentrated *in vacuo*, at about 60° C., and, on cooling, the double salt precipitates. On again concentrating the resulting mother liquor as before, and cooling, another crop of sodium ferrocyanide is obtained. The process is continued until the concentrated solution of the calcium salt

needs to be rejected. Further details are given, and modifications in the process are described, available when evaporation *in vacuo* is dispensed with.—E. S.

Persulphates: Process for the Electrolytic Manufacture of —. Consortium für Elektrochem. Ind. G.m.b.H. Fr. Pat. 351,613, Feb. 20, 1905. *N.L.L.*, page 896.

Lead Oxides: Manufacture of Pulverulent —. C. L. C. Berton. Fr. Pat. 351,812, Feb. 25, 1905.

LEAD, in impalpable powder, dry or moist, and mixed or not with previously formed lead oxide, is roasted for such time as may be needed to produce the oxide (massicot or minium) required. (Compare Eng. Pat. 14,036, of June 20, 1902; this J., 1903, 701.)—E. S.

Lead Acetates: Preparation of —. Gebr. Heyl und Co., G.m.b.H., and A. Wulze. Fr. Pat. 352,050, March 4, 1905.

FRAGMENTS of lead are loosely heaped on a superposed succession of screens arranged within an upright closed vessel, adapted to resist considerable internal pressure. The vessel is nearly filled with dilute acetic acid, and air is forced in through a perforated coil in the bottom of the vessel, under a pressure of about four atmospheres. By this method neutral or basic solution of lead acetate can be obtained, as may be desired. On drawing off the solution and recharging with dilute acetic acid, the apparatus is again ready for use.—E. S.

Sawdust: Treatment of — for the Extraction of Mineral and Organic Chemical Matters. Mme. Laureau, née J. H. Laureau. Fr. Pat. 352,069, March 6, 1905.

SAWDUST, treated with quicklime or with milk of lime, is made into small heaps, sheltered from rain, and when hardened, is lixiviated to obtain in solution the organic and mineral constituents; or the solution may be evaporated to dryness, and the product charred, which product is then treated by ordinary methods to obtain the salts, and also the iodine, bromine, &c., present.—E. S.

Sulphur: Producing —, in the form of very Fine Powder. A. Dementieff. Fr. Pat. 351,981, Feb. 21, 1905.

SULPHUR vapour is brought into contact with water vapour, which may be in the state of superheated steam; or the sulphur may be volatilised directly by the same. The finely divided sulphur thus obtained may be freed from water in a centrifugal separator. A mixture of ordinary flowers of sulphur with the fine powder, may be obtained by conducting the vapour of sulphur into a closed cooling chamber, into which finely-pulverised water is introduced under pressure.—E. S.

Chlorine: Process for Increasing the Chemical Action of —. B. Marguies and Co. Fr. Pat. 352,196, March 8, 1905.

A LIGHT rich in ultra-violet rays is caused to play upon the vessel or apparatus in which chlorine is brought into contact with the substance or substances to be acted upon. The apparatus should be wholly or partially constructed of quartz, or of other bodies such as glass very rich in silica, only feebly absorbent of the rays referred to. An example given of the application of the process is to the chlorination of benzene. The bleaching of fabrics may also be effected under the action of chlorine aided by the rays as described.—E. S.

Marble, Calcareous and Other Natural Stones, Crystalline or Amorphous: Process for Producing Grain in Colours Fast to Light and to Weathering Influence —. Chem.-Techn. Fabr. Dr. A. R. W. Brand and Co. Fr. Pat. 351,591, Feb. 18, 1905.

THE marble or other stone is first impregnated by treatment in a vessel, from which the air can be exhausted, with a cold saturated ammoniacal solution of a metallic salt, such as copper or nickel chloride. The material is then dried at a temperature of about 80° C., and impregnated with a more dilute neutral solution of an alkali salt, such as an alkali phosphate, chromate, cyanide, ammoniate or complex cyanide. This solution acts on the metallic compounds previously introduced into the stone to produce coloured veins and grains. Neither the ammoniacal nor the alkali salt solution must contain sulphates or oxalates.—A. G. L.

Colouring Natural Compact and Crystalline Stone, especially Marble: Process for Completely —. Chem.-Techn. Fabr. Dr. Alb. R. W. Brand and Co. Fr. Pat. 351,590, Feb. 25, 1905. Under Int. Conv., March 25, 1905.

THE marble or other stone is impregnated with a solution of a metallic soap in a volatile oil to which an organic acid has been added. The stone is then dried, when a precipitate, insoluble in water, will be formed in the pores, consisting partly of a basic metal salt of the organic acid, and partly of the carbonate of the metal. For instance, a 30 to 40 per cent. solution of copper oleate in turpentine may be used, the theoretical quantity of acetic acid being necessary for decomposing the copper oleate being added to the solution.—A. from their Ores; Apparatus for the Separation
liquids from Solids, particularly applicable to the
ments of — P. J. Ogle and The Cyanide
um Filter Co., Ltd., both of London. Eng. Pat.
5,6, July 15, 1904.

vention is stated to consist in a modified construc-
the apparatus described in Eng. Pat. 3,962, of Feb.
4 (this J., 1905, 501). A series of filtering elements,
having a separate filtering medium, and an enclosed
s arranged in ring formation, as an endless chain or
Means are provided for operating and for guiding
ments successively into and out of one or more tanks,
so means for exhausting the liquid matter passing
h the filtering medium. The solid matter collecting
filtering medium is discharged into troughs by
of compressed air.—E. S.

Soldering; Material Applicable for — C. H. M. C.
and for Writing or the like, and Material for
the same. M. Leisel, Cologne, and F. Kupper, Bonn-
Endenich, Germany. Eng. Pat. 17,924, Aug. 13, 1904.

SEE Fr. Pat. 345,593 of 1904; this J., 1904, 32.—T. F. B.

Furnaces; Impts. in Gas [Metallurgical] — C. H.
Thompson, Stourbridge, from C. L. Hopied, Vallauri,
France. Eng. Pat. 19,001, Sept. 3, 1904.

The claim is for the construction of furnaces such as are
used for the annealing of malleable iron castings, &c.,
in which the gas producers are placed on the opposite
sides of each furnace chamber. Each chamber has two
flues passing through the sole; the flues can be alternately
connected, the one to the stack and the other to the
atmosphere to admit the necessary air. During the
operation of the furnace, the connections are from time to
time reversed, so that the flues act as regenerators to heat
the incoming air, for which purpose they may, if desired,
be provided with chequer brickwork.—W. H. C.

Ore Concentrators; Impts. in — F. Esser, Cologne,
Germany. Eng. Pat. 27,034, Dec. 12, 1904.

In order to improve the separation obtained with a
reciprocating table, the force of the stream of wash-
water is regulated during the reciprocation of the table.
This is effected by increasing or diminishing the inclination
of the table towards the delivery side during the forward
movement, and bringing it back to its original position
during the backward movement. For this purpose the
table may be carried on wedge-shaped shoes, mounted on
rollers in such a way that those on the feed side incline
in an opposite direction to those on the delivery side.
Or, parallel guide shoes are provided at the feed-side,
and wedge-shaped shoes at the delivery side. Or, the table
may be carried on eccentric rollers, the eccentricity of
the two on the feed side being oppositely directed to that
of the two rollers on the delivery side. Or, the table may
be supported on two pairs of stilts, the pair on the feed
side being longer than the two stilts on the delivery
side, and the fulera of the stilts being located so that the
table makes a tilting as well as a reciprocating move-
ment.—A. G. L.

Metalliferous Minerals; Separation of — from Gangue.
H. L. Subman, H. F. Kirkpatrick-Picard, and J. Ballot,
London. Eng. Pat. 29,374, Dec. 31, 1904.

UNITED STATES PATENTS.

Chromiferous Iron; Treatment of — H. H. Campbell,
Steelton, Pa. U.S. Pat. 795,193, July 18, 1905.

THE chromiferous iron is charged in the molten state into
a basic-lined converter with loose basic material, and the
charge is blown longer than usual, to oxidise the chromium,
and cause it to enter the slag. The metal is then separated
from the slag, and is then charged into an acid-lined con-
verter with silicious material, together with iron free from
chromium, and having a relatively high carbon content,
to reduce metallic oxide in the de-chromised metal, as well
as to furnish additional heat by the combustion of the
carbon.—E. S.

Ore of Art of Treating — and Gathering Gold or
Precious Metal diffused in the unhydrop Mercury. G.
M. Rice, Worcester, Mass. U.S. Pat. 794,552, July 11,
1905.

To a mass of ore under treatment by amalgamation with
mercury, from 2 to 5 per cent. of the weight of the mercury
is added of an amalgamable metal in a finely-divided state.
The total amalgam thus formed is collected, and the mercury
is expelled. Also, to a body of mercury containing gold,
a comminuted metal or metals, other than that sought to
be recovered, but capable of forming an amalgam, is
added, "that will act as a scavenger or gatherer for the gold
when straining or squeezing out the mercury."—E. S.

Zinc: Process of Removing or Recovering from Ores. W. Stewart, Glasgow, Scotland. U.S. Pat. 794,198, July 11, 1905.

THE powdered ores are mixed with an alkali bisulphate and with sodium chloride, and the mixture is furnaceed at a red heat. Zinc salts are recovered from the solution obtained on lixiviating the furnaceed product.—E. S.

Copper Mattes, White Metal, and Blister-Copper; Method of Producing— in a Single Furnace. R. Baggaley, Pittsburg, Pa. U.S. Pat. 794,272, July 11, 1905.

A MOLTEN bath is formed from a low grade copper sulphide ore, in a furnace in which the charge is heated by flames from above upon the surface of the bath, whilst air is blown through from below. The slag is drawn off, and addition is made from time to time by small portions of silicious metal-bearing ores to flux the iron of the matte and to increase the yield of metal. The outlet for the gases issuing from the melting chamber is constricted, and is regulated according to the heat requirements of the bath. In the final stage of the process, the enriched and concentrated matte or metal is collected into a non-heat-conducting cavity situated below the bath. (Compare U.S. Pats. 746,241, 746,246, 746,249 and 746,269, all of Dec. 8, 1903; this J., 1904, 23.)—E. S.

Ore Concentrator. H. Scovell, H. B. Scovell, L. E. Scovell and W. E. Scovell, Galena, Kans. U.S. Pat. 749,555, July 11, 1905.

A SCREEN, the forward portion of which has a sharp upward curve, whilst the other end has a slight upward inclination, is placed in a tank containing a liquid, and receives the crushed ore from a shoot. A compound vertical and horizontal motion is given to the screen by an arrangement of shafts and cams suitably operated. The concentrate falls through the screen, whilst the waste passes over the tail of the screen.—J. H. C.

Metalliferous Materials; Process of Purifying and Nodulizing— T. C. King, Marion, Ala., Assignor to National Metallurgic Co., Jersey City, N.J. U.S. Pat. 794,673, July 11, 1904.

A "BINDER" which is adhesive at low and volatile at higher temperatures, is mixed with the finely divided metalliferous material, which is then heated in a suitable vessel to temperatures ranging from 1200° F. upwards, so as to volatilise the binder together with certain volatile impurities, the whole mass being agitated so as to form nodules which are finally fused into permanent form.

—J. H. C.

Slag-Furnace. O. S. Garretson, Buffalo, N.Y. Assignor to Garretson Furnace Co., Pittsburg, Pa. U.S. Pat. 795,032, July 18, 1905.

ACCORDING to this invention, the heat evolved during the cooling of slag is utilised in raising steam in a boiler, or for similar purposes. The molten slag is delivered on to a series of congealing rollers, through which a cooling agent is passed. These rollers deliver the congealed slag to an upright chamber, where it is further cooled by a continuous current of air which flows through a passage opening into the lower portion of the slag-chamber, and then in succession through the column of slag, through the heating flue of the steam boiler or the like, and back through the passage to the bottom of the slag chamber. The cooled slag is removed from the bottom of the chamber by means of a conveyor. (Compare U.S. Pats. 728,794, and 728,795 of 1902; this J., 1903, 747.)—A. S.

FRENCH PATENTS.

Copper; Process for imparting to —, Resistance and Hardness, without Discoloration. H. Herreschmidt, L. Renault, and A. Monier. Fr. Pat. 349,902, May 7, 1904.

AN alloy of copper, vanadium and cobalt is obtained by heating a mixture of oxides of these metals with carbon or the like for some hours. The alloy thus obtained is melted with copper in such proportion that the new alloy may contain copper, 94 per cent., cobalt, 4 per cent., and vanadium, 2 per cent.—E. S.

Minerals; Process of Smelting —. J. Gayley. Fr. Pat. 352,244, Jan. 16, 1905. Under Int. Conv., Oct. 1904.

SEE U.S. Pat. 779,037 of 1905; this J., 1905, 138.—

Minerals [containing Nickel and Cobalt]; Tre of —. J. Savelsberg. Fr. Pat. 351,535, Feb. 1905.

THE treatment is applicable to minerals, such as Caledonian nickel-cobalt ores, which do not contain sufficient sulphur to give a matte by direct smelting. These minerals are mixed with sulphur, or with materials containing materials, such as pyrites, sulphate sulphides, together with a little carbon and a flux. The mixture is then treated in a converter in a current of gas, the heat disengaged during the reaction which place being sufficient to maintain the temperature sufficiently high when once the action has been started. An agglomerated mass is obtained containing the metal in the form of sulphides; this mass is broken up into small pieces which are smelted for matte as usual.—A. G. L.

Metalliferous Minerals; Process for Separating Gangue from —. H. L. Sulman, H. F. K. and J. Ballot. Fr. Pat. 351,846, Feb. 27, 1905.

THE powdered mineral or ore, made into a paste with water, is distributed upon a movable table, or an inclined vanning table, over which currents of, preferably, luted water are passed transversely, whilst air-curtains are directed upon the immersed or floating particles to direct the metallic particles, sustained on the surface by the adhering oil, in one direction, whilst the gangue, which, being comparatively free from oil, sinks, are swept in a contrary direction. In an apparatus, the ore powder, after treatment with water, is distributed upon a movable concave inclined floor, which, by an oscillatory movement, upon which floor no jets of water play, so that the immersed powder is exposed to air towards the margin; the metallic particles to which oil adheres then float downwards, while the gangue which sinks is carried to discharge end. (Compare Eng. Pat. 20,419 of Sept. 22, 1903; this J., 1904, 1150.)—E. S.

Cement; Manufacture of Products similar to — from Blast-Furnace Slag. A. F. Le Chatelier. Fr. Pat. 351,821, Feb. 25, 1905. IX., page 893.

GERMAN PATENT.

Gold; Process for Accelerating the Solution of — in Cyanide Solution. F. W. Dupré. Ger. Pat. 190,400, May 5, 1904.

CLAIM is made for the addition of an alcohol, preferably ethyl alcohol, to the cyanide solution. The power of aqueous cyanide solution for gold depends on the dissolved oxygen it contains; an addition of alcohol which is capable of dissolving seven times more oxygen than water, thus favours the solution of gold. An addition of even a few parts per cent. of methyl or ethyl alcohol causes a considerable difference in the solvent power of the solution. A larger addition of alcohol has the advantage of diminishing the amount of deleterious gangue constituents dissolved.—A. S.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(A.)—ELECTRO-CHEMISTRY.

Anodes, Magnesium; Behaviour of —. G. Balbo. Z. Elektrochem., 1905, 11, 1865, 482.

THE author has found that the polarisation of magnesium when employed as anode, is marked by the following characteristics:—

1. In neutral solutions of chlorides and sulphates hydrogen is liberated at the surface of the anode, and the

becomes covered with a black powdery deposit, most probably metallic magnesium and not the

or these conditions, the relation between the magnesium dissolved and the current passed is to a fairly constant apparent valency of 1.30 metal, this relation being independent of the re, concentration or composition of the electro-

potential difference at which the magnesium dissolved in neutral solutions, agrees fairly well given by metallic magnesium in a cell in which it is passing. This last-named potential varies 0 to -2.10 volts.

tempts to form the supposed sub-oxide of magnesium the anode failed; only mixtures of the metal cesium oxide (MgO) could be obtained.

alkaline solutions three conditions of the surface magnesium anode are to be distinguished—the passive, and the pseudo-active.

in the active and passive conditions the anode liberates oxygen. The apparent valency magnesium passing into solution is about 9. magnesium anode in solutions containing both hydroxide and potassium chloride in certain degrees of concentration, evolves both oxygen gas, each of these being localised reactions.

consequence of these special characteristics of an, when used as anode material, the following and reductions are possible:—

neutral solutions, potassium permanganate and can be reduced, while iodine ions are oxidised to molecules.

alkaline solutions, bromine and iodine ions are o bromate and iodate ions respectively, potassium is reduced (probably to manganate), chlorine ions remain unaltered.—J. B. C. K.

Al; Reduction of — to Stearic Acid by Electrolysis. J. Petersen. Overs. over det Kgl. Danske Vidensk. Selsk. Forh., 1905, 137—149. Chem. 1905, 2, 304—305.

author has carried out some experiments on the reduction of free oleic acid in hydrochloric sulphuric acid solution. In the first experiments of oleic acid dissolved in 150 c.c. of alcohol and dilute sulphuric acid were used with a nickel wire (in later experiments a cathode of nickel wire was employed), a diaphragm, and a platinum anode into sulphuric acid. With an E.M.F. of 20 volts current of 1.35 amperes, a good yield of stearic acid melted at 32° C. In alcoholic sulphuric acid solution best yields were obtained with the smaller proportion of acid. In experiments with hydrochloric acid, 1/1 acid was added to 100 c.c. of the solution acid, and electrolysis effected with a current of 1 ampère. The reduction effected was greater, the solution of oleic acid had been in contact with hydrochloric acid. During the electrolysis the yield of acid gradually diminished. The yields are better with hydrochloric acid than with sulphuric acid. It is preferable to add the acid drop by drop during the electrolysis in order to avoid too great an increase of temperature. (out 20 volts, 1 ampère, 30°—35° C. are the best conditions). With increasing current-density, the yield of stearic acid decreases; the temperature is without effect.—A. S.

Acetylene; New Carbon —. J. W. Howell. Eng. Pat. 882.

Electrolytic Determination of — for Technical Purposes. K. Jene. XXIII., page 905.

ENGLISH PATENTS.

Heating Water Electrically; Apparatus —. M. H. Shoenberg. San Francisco, U.S.A. Eng. Pat. 2328, Feb. 6, 1905.

SEE Fr. Pat. 351,149 of 1905, following the Eng. Pat. 882. *Gases; Apparatus for Producing "Electric" Reactions in —, by Aid of Electric Arcs.* K. Eriksen. Christiania, Norway. Eng. Pat. 3525, Feb. 20, 1904. Under Int. Conv. Feb. 20, 1904.

This invention relates to a furnace for producing chemical reactions by the aid of electric arcs formed between electrodes arranged in a strong magnetic field. The electrodes are placed near to one end of the furnace, and are provided with long extensions or horns, which extend through the furnace chamber near to opposite sides of the same.—B. N.

Dye-stuffs; [Electrolytic] Manufacture of Leuco-gallotannic —. G. W. Johnson. From the Dyeworks, formerly L. Durand, Huguenin and Co. Eng. Pat. 7835, April 12, 1905. IV., page 885.

UNITED STATES PATENTS.

Battery; Electric Storage —. A. Meister and A. Junker. New York. U.S. Pat. 794,240, July 11, 1905.

This invention relates to a means for forming a coating of oxide on a metal anode, such as nickel, the surface of the anode being covered with a porous and absorbing material. The electrolyte consists of dilute caustic potash and carbolic acid, or a phenolate may be used with a suitable cathode.—B. N.

Furnace; Electric —. C. L. Saunders. Cleveland, Ohio. U.S. Pat. 794,255, July 11, 1905.

THE hearth of the furnace consists of a horizontal continuous annular trough, with positive and negative electrodes supported on or embedded in opposite sides, the electrodes being adapted to convey current to and from the material. The hearth is rotated continuously, and a series of contact pieces carried by the hearth and connected with the electrodes make temporary contact with stationary contact pieces which are in connection with the source of current. As the hearth rotates, successive currents are passed through the material, thus increasing its heat and decreasing the resistance throughout the whole of the material. Means are provided for charging the hearth and for removing the material. A portion of the hearth is enclosed by a cover, which is provided with an arrangement for leading away the gases generated during the process.—B. N.

FRENCH PATENTS.

Accumulator; New Electric —. W. Gardiner. Fr. Pat. 351,884, Feb. 28, 1905.

THE positive electrode of the accumulator is composed of a small tube of copper, closed at both ends, and enclosed in a cylinder of perforated sheet copper, the intervening space being filled with a mixture of silver and nickel amalgams. This electrode is insulated from the negative pole which surrounds it, and which consists of copper wire gauze in contact with the walls of the containing vessel, which are of conducting material. The containing vessel has a gas-tight cover in which are openings for the introduction of the electrolyte, these openings having stoppers provided with valves which prevent air entering, but allow any gas evolved to escape.—A. S.

Batteries; Elements for Electric —. W. Gardiner. Fr. Pat. 351,886, Feb. 28, 1905.

THE claim is for a battery in which the electrodes are disposed horizontally, in order to prevent the active material deposited on them from being dislodged. The containing vessel is made of conducting material, such as metallic copper, and on its bottom are one or more layers of copper gauze which constitute the negative electrode. A framework of ebonite or other insulating substance separates this electrode from the anode, which consists of two perforated plates, with the active material between.

The plates are of silver, nickel, platinised copper or other metal capable of resisting the action of the electrolyte. On the lower one is stretched a piece of porous fabric, which serves as a support for the active material. The latter consists of a mixture of silver and nickel amalgams; it is held in place by a framework furnished with laths, and by the upper metal plate. The electrolyte consists of a solution of caustic potash to which is added zinc or cadmium oxide.—A. S.

Battery: Secondary —, W. Gardiner. Fr. Pat. 351,392, Feb. 28, 1905.

SEE Eng. Pat. 27,900 of 1904; this J., 1905, 625.—T. F. B.

Insulating Material: Electrical (C. Porphyrite). A. and L. Parvlee. Fr. Pat. 352,181, March 8, 1905.

THE invention has for its object the preparation of a new product, named "porphyrite," which constitutes a novel electrical insulating material, neutral in colour, absolutely impermeable, of great compactness, and possessing a high mechanical resistance and electrical resistance. It is prepared by combining together 40 parts of clay or kaolin, 30 parts of rock porphyry, and 30 parts of bauxite calcined at a high temperature or melted in the electric furnace. The product is richer in alumina than any other known insulating body. — B. N.

Nitrogen: Process for the Oxidation of Atmospheric —, by means of Electricity. D. Hebbig. Fr. Pat. 352,080, Jan. 20, 1905. Under Int. Conv., Jan. 21, 1904.

Air, alone or mixed with other gases, is submitted to the action of an electric arc, which is maintained between metallic electrodes, the points of the latter being provided with covering refractory material which ionises the gas at a high temperature. The arc is enclosed by a covering of refractory material which also ionises the gas at a high temperature, and which is so disposed that the whole of the gas traversing the apparatus is submitted to the action of the arc. The cold gas enters through channels surrounding those by which the hot gas makes its exit, and thus the gas receives heat before it reaches the arc. — B. N.

Liquids: Apparatus for Heating — Electrically. The Schoenberg Electric Appliance Co. Fr. Pat. 351,449, Feb. 11, 1905.

THE liquid to be heated is circulated through a hollow, vertical, cylindrical vessel, constructed of porcelain or some other insulating material, with ends of metal, to which the wires carrying the current are attached. The current flows through a spiral metallic conductor, immersed in the liquid and connected to the two metal ends of the cylinder. The liquid enters the cylinder at the lower end, by an insulated pipe and passes away at the top by another insulated pipe. The supply of liquid is controlled by a tap, placed on the feeding pipe and so arranged that it must be opened before the circuit is completed, and the circuit must be broken before the tap can be closed; in this way any overheating of the coil, which might damage it, is prevented.—W. H. C.

Persulphates: Process for the Electrolytic Manufacture of —, Consortium für Elektrochem. Ind. G.m.b.H. Fr. Pat. 351,613, Feb. 20, 1905.

It has not hitherto been possible to obtain good yields of potassium and sodium persulphates by the electrolytic process. The patentees have found that the yield of persulphate increases concurrently with the potential at the anode, and that the latter can be raised by the addition of certain substances, notably, hydrofluoric acid, to the electrolyte. The favourable action of the hydrofluoric acid, however, gradually diminishes as electrolysis proceeds, owing to the production of monopersulphuric acid (Caro's acid). To prevent the formation of this acid, the rate of its production under the working conditions is determined by a preliminary test, and then during the electrolysis the necessary quantity of a reducing agent is added continuously to the electrolyte. Suitable reducing agents are sodium bisulphite or sulphite, hydrochloric acid, or sodium chloride, the two latter exerting a specially favourable influence as the chlorine ions dis-

engaged raise the potential at the anode and thus increase the yield of persulphate. (Compare Müller, this J. 1904, 987.)—A. S.

(B).—ELECTRO-METALLURGY.

Silver: Electrolytic Separation of —, R. C. Snowden. J. of Phys. Chem., 1905, 9, 392—398. Chem. Centr. 1905, 2, 106.

THE author determined the influence of current-density and concentration of the electrolyte on the nature electrolytically deposited silver. It was found that the size of the silver crystals decreased with increasing current density. It is advantageous to rapidly rotate the cathode (2000 revolutions per minute), and to separate the anode and cathode compartments. The size of the individual crystals is only slightly less in nitric acid solution than in neutral solution. If gelatin be added to the electrolyte the silver is deposited in an amorphous condition.—A.

Nickel: Electrolytic Deposition of — on Nickel. R. Snowden. J. of Phys. Chem., 1905, 9, 399—404. Chem. Centr., 1905, 2, 105.

It is known that an adherent deposit of nickel on nickel can only be obtained under certain conditions. The deposit is always non-adherent when the support is composed of electrolytic nickel. It has been generally thought that this is due to the formation of a hydride or to the occlusion of hydrogen by nickel. The author's view, however, is that it is due to the formation of a layer of oxide. The surface of the support can be rendered capable of receiving an adherent deposit by reduction, for example, by cathodic polarisation. This action is, however, very unstable, and the reduction must, therefore, be effected immediately before use.—A.

Chromium: Electrolytic —, H. R. Carveth and B. E. Curry. J. of Phys. Chem., 1905, 9, 353—357. Chem. Centr., 1905, 2, 102—103. (See this J., 1905, 625.)

IN the electrolytic separation of chromium from solutions of alkali chromates, it has not hitherto been definitely ascertained whether the chromium exists only in the form of anions, or whether hexavalent cations are also present. On electrolysing solutions of commercial chromic acid, using a high current-density, a metallic precipitate is obtained, which contains a large quantity of occluded hydrogen. With pure chromic acid the yield is very small, but is better in presence of sulphuric and other mineral acids. In strongly acid solutions chromium trioxide behaves as a base, hexavalent chromium cations being split off. In all solutions in which reduction has taken place, the cathode liquid will give the reaction of chromic salts. If the solution be alkaline, a brown precipitate of chromic chromate is produced. Under suitable conditions more than half of the total chromium can be separated electrolytically from chromic acid.—S.

UNITED STATES PATENT.

Process: Metallurgical — G. H. Benjamin, New York, N.Y. U.S. Pat. 794,212, July 11, 1905.

The furnace consists essentially of a roasting chamber, a heating chamber, an electrically heated chamber and an oxidising chamber, arranged at progressively lower levels. The ore is moved along the inclined bottom of the roasting chamber by means of a rake, and passes into the reducing chamber, in which a reducing atmosphere is maintained. This chamber discharges into the top of a vertical electrically-heated chamber, as also does an independent, rotating chamber in which the fluxes, &c., are heated. The mixture of ore, fluxes, &c., in the rotating chamber is subjected to the heat in the electric arc. The molten material flows out at the bottom into a basin or well, in which a separation of the different components is effected by gravity. The molten metal flows from the basin to the hearth of an oxidising chamber, where it is subjected to the action of a blast of air. The flues leading from the basin to the oxidising chamber discharge around the rotary heating chamber and into the reducing chamber, the latter being provided with an exit flue.—A. S.

FRENCH PATENT.

Magnesium and other Substances in Acid or Neutral Solution; Electrolytic Recovery of — Decker Manufacturing Co. Fr. Pat. 352,029, March 3, 1905.

The invention relates to an apparatus comprising a tub containing the electrolytic solution, the vessel being closed by a partition pierced with one or more openings, in each of which is lodged a trough. The ends of each trough are furnished with projecting pieces fitting into the ends of the trough below, and the sides are sloping, the bottom being inclined towards the outside. The troughs contain mercury, which closes the openings of the partition. The troughs are all connected together electrically. The troughs are also provided with overflow pipes, so that the mercury poured into the upper trough passes down successively from one trough to the next below.—B. N.

GERMAN PATENTS.

Soldering Metal Objects; Electrical Process for — V. Fuhrmann. Ger. Pat. 159,718, Dec. 28, 1902.

The process is for the purpose of soldering metal objects having a large superficial area, but only a small soldering face. An auxiliary electrode is used, and this is placed in contact with the part or parts to be soldered and also with the solder, and the soldering is effected with the aid of an electric current.—A. S.

Process for the Direct Electrolytic Preparation of Pure Copper — using Copper Ore as Anode in an Electrolyte consisting of an Acid Solution of Copper Sulphate. W. Borebers, R. Franke and E. Günther. Ger. Pat. 160,046, Oct. 5, 1904.

Copper ore used as anode is subjected to a preliminary leaching of concentration until its percentage of copper is above 72 and as nearly as possible 78–80. It is stated that only by maintaining the proportion of copper in the electrolyte between these limits does the direct electrolytic manufacture of copper become remunerative. The chief difficulty in the direct electrolytic process is the deposition

of sulphur at the anode, but by working under the conditions mentioned, it is stated that with a current density of about 50 amperes per sq. m. of cathode or anode surface, and with the usual agitation of the electrolyte, it is possible to keep the P.D. below 1 volt at the ordinary temperature even after deposition of a considerably thick layer of sulphur at the anode. A. S.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

Bean Oil [Soja Bean Oil]; Characteristics of Chinese — W. Korentschewski and A. Zimmermann, Chem. Zeit., 1905, 29, 777–778.

SOME 20 different species of these beans are sold under the name "doutsu," some being used as human food, others as fodder for cattle, and others again for the extraction of the oil. A kind of vernicella is also prepared from certain species. The oil is expressed by means of a primitive plant in the Chinese factories and exported in large quantities to Japan and Korea. The method of extraction consists in first crushing the beans into caked masses by means of mill stones, then heating them on stone slabs until the appearance of vapours, and finally expressing them in an iron receptacle. As first obtained the oil is turbid, but after some time becomes clear, the deposit consisting of sand particles and vegetable fibres. Only the clear oil is exported, but the turbid oil is sold locally. It has a faint odour recalling that of Chinese wood (tung) oil, is bland to the taste, and of a dark brown colour. Four commercial samples examined by the authors (one being obtained direct from the factory in Kharbin) gave the following results:—Water, 0.3 to 1.80 per cent.; sp. gr. at 15° C., 0.9264 to 0.9287; solidification point, –14.6° to –15.3° C.; saponification value, 207.9 to 212.6; ester value, 203.9 to 207.7; insoluble fatty acids, 93.6 to 94.28 per cent.; iodine value (Hübl), 114.8 to 137.2; solidification point of fatty acids, 16° to 17.3° C.; m.p. of fatty acids, 20° to 21° C.; Maumené test, 192° to 116° C. and acid value 1.86 to 15.46. It was concluded that the oil contained a large proportion of olein. Practical tests showed that the oil was readily absorbed by the system and possessed a high food value.—C. A. M.

Oleic Acid; Reduction of — to Stearic Acid, by Electrolysis. J. Petersen. XLA., page 895.

ENGLISH PATENT.

Soap; Process of and Apparatus for Producing Bars of — K. E. Markel, Warrington. Eng. Pat. 23,187, Oct. 27, 1904.

THE liquid soap is forced into intermittently revolving cooling tubes, and solidified by immersing these in a cooling medium, after which the solid bars are expelled by a further quantity of liquid soap, which, in turn, is treated in the same way. The bars are pressed out of the tubes against a spring piece, so as to minimise the difference between the outer and inside friction, and to counteract the decrease of friction as the bars issue from the tubes. The face of the spring piece is a solid block, to keep the ends of the bars level. The soap is delivered to the tubes through a jacketed pipe, and cut-offs are provided at each end of each cooling tube, and at the end of the delivery pipe.—C. S.

UNITED STATES PATENT.

Oil and Moisture from Materials; Apparatus for Extracting — S. E. Wilson, Cincinnati, Ohio. U.S. Pat. 795,183, July 18, 1905.

A STEAM-TIGHT telescopic casing is arranged around a press so as to enclose the material being pressed. The casing stands in a pan carried by the bottom plate or "platen," and is provided with a telescopic door. By means of pipes steam can be introduced into the casing so as to act directly upon the material in the press.

—W. H. C.

FRENCH PATENTS.

Oils or Fats; Treatment of — before Saponification with Castor Oil Seeds or the Hydrolysis of Oleaginous Seeds. M. Nieloux and E. Urbain. Fr. Pat. 349,942, May 26, 1904.

The presence of acids in the oils to be treated causes irregularities in the enzymic process, and claim is made for the removal of such acids either by washing the oils first with acidulated water and then with pure water, or, preferably, by neutralising the free acids with sodium carbonate and removing the soap. This treatment greatly increases the yield of fatty acids within a given time. Thus a coprah oil, which only yielded 70 per cent. of fatty acids, gave 95 per cent. after removal of the free acids. The glycerol solutions obtained from the purified oils are perfectly colourless.—C. A. M.

Gas; Process for Obtaining Producer — from Vegetable Refuse from Oil Factories. O. Hentschel. Fr. Pat. 351,533, Feb. 15, 1905. II., page 883.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

(A).—PIGMENTS, PAINTS.

Ultramarine Blue. K. A. Hofmann and W. Metzner. Ber., 1905, 38, 2482—2486.

The authors find that ultramarine blue is not decolorised, and remains practically unchanged in composition, by the action of strong sulphuric acid or glacial acetic acid. Strong sulphuric acid actually exercises a protective effect against the action of nitric and nitrous acids on ultramarine. Ultramarine is also unattacked in presence of acetic anhydride by glacial acetic acid saturated with hydrochloric acid. In absence of acetic anhydride there is gradual decomposition, but the siliceous part of the substance is mainly attacked and the blue colour remains. Ultramarine blue is also unaltered by a solution of bromine in a mixture of glacial acetic acid and acetic anhydride. The authors conclude that ultramarine blue probably owes its blue colour to compounds of similar nature to sulphur sesquioxide, S_2O_3 , described by R. Weber (Pogg. Ann. 158, 531), and not to groups of similar character to those present in polysulphides and thiosulphates.—E. F.

FRENCH PATENTS.

Lead Carbonate [Pigment]; Preparation of —. Gebr. Heyl and Co., G.m.b.H., and A. Wultze. Fr. Pat. 352,049, March 4, 1905.

Carbon dioxide is led into a solution of lead acetate in such manner that the gas, on reaching the solution and for a fraction of a second afterwards, is under a certain pressure. This may be effected by causing the gas to issue into the solution through a wide, valved outlet from a vessel containing the gas under a pressure of from three to four atmospheres, so that the pressure rapidly diminishes as the gas passes out. The lead carbonate thus obtained is stated to be non-crystalline, and to be specially suitable for use as a pigment.—E. S.

Antimony; Process and Apparatus for Treating Minerals Containing —, and for Obtaining a Pigment by Aid of such Minerals. J. S. MacArthur. Fr. Pat. 352,136, March 6, 1905.

(C).—INDIA-RUBBER, Etc.

Balata. A. Tschirch and E. Schereschewski. Arch. Pharm., 1905, 243, 358—377.

BALATA which is obtained from *Mimusops globosa*, Gärtn., is the most important technical substitute for gutta-percha. It occurs in commerce in the form of leathery, elastic sheets that soften at 49° — 50° C., then become

plastic, and melt at 149° — 150° C. The material examined by the author contained 5.7 per cent. of matter soluble in boiling water, 41.5 per cent. soluble in boiling alcohol, 42.5 per cent. in boiling acetone, 87.0 per cent. in boiling ether, and 86.8 per cent. soluble in chloroform. Analysis it gave 1.72 per cent. of moisture, 0.96 per cent. of ash, 41.5 per cent. of "resin" (extracted by boiling alcohol), and 45.3 per cent. of "gutta" (extracted by boiling chloroform from the product after removal of the "resin"). 500 grms. of the balata were cut into small pieces exhausted successively with boiling water, boiling alcohol, and chloroform, and the solutions examined separately. From the aqueous solution, an albuminoid substance separated by precipitation with tannic acid, and the "gum" by treatment with alcohol. The yield of was 1.5 per cent. of the weight of balata; it contained 6.47 per cent. of ash, was optically inactive, but analogous to reactions for carbohydrates and for furfural. From alcoholic solution it is stated that there were isolated α -balaban, $C_{27}H_{42}O_2$, m.p. 230° — 231° C.; β -balaban, $C_{27}H_{42}O_2$, m.p. 108° — 109° C.; and β -balafuavil, $C_{10}H_{16}$ (yield, about 1.5 per cent.). The resinous constituent of balata do not contain esters of cinnamic or other acid. Examination of a number of specimens of gutta-percha of different origins showed that the presence or absence of esters of cinnamic acid does not afford a means of distinguishing balata from gutta-percha, some specimens of the latter yielding cinnamic acid on hydrolysis with alcoholic caustic potash, whilst others do not (see this J., 1904, 1103.). From the chloroform extract of balata, β -balagutta, $C_{10}H_{16}$, which rapidly undergoes change when exposed to the air, and β -balaban, $C_{27}H_{42}O_2$, m.p. 55° — 56° C. were isolated. Tabular data are given in which the behaviour of the alban, fluavil, and albanan from balata when subjected to different chemical reactions is compared with that of phytyl. (See also this J., 1905, 627.)—A. S.

Gum Chicle; The So-called —. A. Tschirch and E. Schereschewski. Arch. Pharm., 1905, 243, 378—393.

GUM chicle, the concentrated latex of *Archras Sapota*, is obtained chiefly from Mexico, and is used exclusively in the United States for the preparation of "chewing gum." The specimen examined by the author contained 16.8 per cent. of matter soluble in boiling water, 59.7 per cent. soluble in boiling alcohol, 61.7 per cent. in boiling acetone, 76.2 per cent. in boiling ether, and 77.2 per cent. soluble in chloroform. It was treated in the manner described in the preceding abstract for balata. The compounds isolated were:—An optically inactive gum (yield, 9 per cent.) containing 3.76 per cent. of ash; α -chicalban, $C_{24}H_{40}O$, m.p. 219° — 221° C.; β -chicalban, $C_{18}H_{30}O$ or $C_{17}H_{28}O$, m.p. 158° — 159° C.; γ -chicalban, $C_{15}H_{24}O$, m.p. 86° — 87° C.; β -chidafuavil, $C_{10}H_{16}$, or $C_{10}H_{20}O$ (yield, 1.5 per cent.), m.p. 66° — 67° C.; β -chidagutta, $C_{10}H_{16}$ or $C_{10}H_{18}$; and β -chidabalan, m.p. 57° C. (See also this J., 1902, 438; 1903, 1358.)—A. S.

ENGLISH PATENT.

Fabrics; Apparatus for Treating Tubular — with Liquid or Semi-liquid Compositions. W. R. Eng. Pat. 26,005, Nov. 29, 1904. V., page 887.

XIV.—TANNING, LEATHER, GLUE, & Etc.

Quebracho Tannin. M. Nierenstein. XXIV., page 007.

Tanning Materials; Study of some — capable of producing "Bloom." M. Nierenstein. Collegium, 1905, 21—23, 197—200.

TANNIN substances which are pyrogallol derivatives possess the characteristic property of producing the surface of leather tanned with them, so-called "bloom," which consists essentially of ellagic acid. With regard to this deposition of ellagic acid on the fibres of the hide, the author is of the opinion that the acid exists in the

ning material in the form of a soluble glucoside, and a gallic acid according to the two formulæ which have been proposed for it by Barth and Goldschmidt (Ber., 9, 12, 1253), viz.,

by Graebe (Ber., 1903, 36, 212) has the power of giving a tanning action on hides, owing to the presence of "tannophor" group, O.CO. , a number of pyrogallol tanning materials were subjected to a detailed examination. (The groups designated "tannophors" by the author are CHO , CO , and CO.O).

Myrobalans (*Terminalia Chebula*).—Thirty grms. of robalans were extracted first with a litre of cold water then with a litre of hot water, and the solution was allowed to stand. The ellagic acid which separated had a faint yellow colour. After filtering, the solution was acidified with 15 c.c. of sulphuric acid, boiled for 20 minutes, cooled, and again filtered. The ellagic acid separated in this way was of a dirty grey colour. The residue was extracted first with ether and then with ethyl acetate, and the two extracts and also the residual aqueous solution were examined separately. In the etheral solution, gallic acid and tannin were detected; in the ethyl acetate solution, gallic acid; and in the aqueous solution, dextrose.

Algarobilla (*Cassia bryonia*).—Algarobilla beans contain about 40—45 per cent. of a tannin of the pyrogallol type, which, if fermentation be prevented, gives a light-brown leather, the cross-section of which has a bluish tint. The author has observed that the methyl ester of gallic acid when treated with excess of milk of lime, gives a deep blue colour which disappears on shaking in presence of air. Since algarobilla beans contain this ester of gallic acid, it is probable that the blue tint mentioned above is caused by the formation of the blue lime compound in the interior of the hide where it is protected from oxidation. This view was confirmed by the fact that skins tanned with myrobalans (which do not contain this ester) in the presence of 3 grms. of the methyl ester of gallic acid, acquired a bluish tinge during the tanning process.

145 grms. of algarobilla beans were extracted with 100 litres of hot water and the solution allowed to stand for three days, in the course of which about 20 grms. of a red, crude ellagic acid separated. In the aqueous solution by suitable treatments, the presence of gallic acid, the methyl ester of gallic acid and a glucoside yielding tannin and dextrose was detected. The red, crude ellagic acid was extracted with alcohol to remove a colouring matter. From the alcoholic solution crystals were obtained, which, after fusing with caustic alkali at 185°C ., gave reactions for phloroglucinol and ellagic acid.—A. S.

Other; Formation of —. Preliminary Communication. M. Nierenstein. Collegium, 1905, 159—160.

PIECE of hide which had been treated with formaldehyde was boiled several times with water, until the presence of a free aldehyde could no longer be detected. The leather was then boiled for three hours with 25 c.c. of water and 1 c.c. of $\text{N}/25$ sulphuric acid, and it was found that formaldehyde could now be detected in the solution, having evidently been liberated from chemical combination. The group CHO is accepted as a "tannophor" (see following abstract), the tanned hide or leather may be regarded as having a formula similar to that of Schiff's base, according to the equation:—

the vegetable tanning materials be regarded as tannone-carbonic acids, in which either the CO or the CO.O group

acts as a "tannophor," the formation of a tanned leather may be expressed by the equation

"Tannophor," $\text{C} \begin{smallmatrix} \diagup \\ \diagdown \end{smallmatrix} \begin{smallmatrix} \text{O} \\ \text{O} \end{smallmatrix}$; Th. —. M. Nierenstein. Collegium, 1905, 221—222.

IN 1872 (Ber., 5, 25, 280, 1096) von Baeyer found that pyrogallol when condensed with formaldehyde, yields an amorphous compound soluble in water, which precipitates gelatin from its solutions, and has, in general, properties resembling those of tannin. Caro (Ber., 25, 947) and also Kahl (Ber., 31, 144), who repeated the experiments, found that phenols or phenol-carboxylic acids when condensed with formaldehyde, form diphenylmethane derivatives, pyrogallol yielding hexahydroxydiphenylmethane, $(\text{HO})_3\text{C}_6\text{H}_2\text{CH}_2\text{C}_6\text{H}_2(\text{OH})_3$, but do not mention the formation of the compound observed by von Baeyer. Having regard to the fact that diphenylmethane compounds contain no "tannophor" group (see preceding abstracts) and therefore do not possess a tannoid character, the author repeated von Baeyer's experiments on the one hand, with pyrogallol, and, on the other, with gallic acid. It was found that in both cases, together with insoluble diphenylmethane derivatives, soluble compounds, capable of forming insoluble precipitates with gelatin, were also formed. The soluble compound produced from gallic acid proved to be the hexahydroxyaurinecarboxylic acid of Caro,

whilst that from pyrogallol was probably the compound,

both of which substances contain the "tannophor" group CO.O .—A. S.

FRENCH PATENTS.

Tanning; Rapid Process of —. R. Berthon. Fr. Pat. 351,661, Feb. 16, 1905.

SKINS which have been saturated with a solution of chromic acid and common salt are tanned very quickly by vegetable tanning materials, chromium oxide being deposited on the fibres of the hide, and the fixation of the tannin being accelerated by the action of the chromic acid, so that a kind of double tanning by bark and by chrome is effected. Free chromic acid, however, has an injurious action on the hides, and claim is made therefore for the use of a mixture capable of yielding free chromic acid for the preliminary treatment of hides to be tanned by the "tanno-chromic" process. A suitable mixture consists of water, 100; sodium bichromate, 5; sodium bisulphate, 10; and sodium chloride, 15 parts.—A. S.

XVI.—SUGAR, STARCH, GUM, Etc.

Cane Sugar Works; Steam in —, P. Bouvier. Bull. Assoc. Chim. Sucr. Dist., 1905, 22, 1149-1155.

RESULTS obtained at a cane sugar factory, working cane of the average richness of 14 per cent. of sugar and with well-served furnaces, show that extraction by mills is the only process which allows of the whole of the heating being done exclusively with bagasse. In a factory working with mills, no other fuel than bagasse is needed, and this result may be attained by either improving the heating apparatus or drying the bagasse, or both. The combustion of relatively dry bagasse shows a considerable advantage and the practical realisation of mechanical drying should be regarded as a necessity. The above conclusions relate to bagasse containing 33 per cent. of moisture; in certain cases a reduction in the moisture may be of advantage.

—L. J. DE W.

Sugar Syrups; Viscosity of —, G. Fouquet. Bull. Assoc. Chim. Sucr. Dist., 1905, 22, 1186-1206.

THE viscosity of syrups increases very greatly with the concentration, particularly above 50 Brix. There is an enormous increase in the viscosity when the temperature of the syrups falls below 60° C.; it varies inversely as the cube of the temperature. Comparing syrups of the same density, the viscosity diminishes with diminished purity and the diminution is proportional to the weight of non-sugar per 100 grms. of syrup. The viscosity at the crystallising point increases with the impurity of the syrup. Of two syrups of the same quotient of purity, the more viscous is the one in which the ratio of organic matter to sugar is higher, and the same holds good at the point of crystallisation. The viscosity of the mother syrup of a massecuite when cooled increases, but not in a great proportion, provided always that the syrup merely remains saturated. When it becomes supersaturated, the viscosity increases enormously. If the supersaturation varies from 1 to 1.44, the viscosity varies from 1070 to 2434. Sulphiting and other such processes appear to produce only a very slight diminution in viscosity. —L. J. DE W.

Disaccharide; Synthesis of an Octamethylated — from Dextrose. Methylation of Sucrose and Maltose. T. Purdie and J. C. Irvine. XXIV., page 903.

Sugar Juices; Manufacture of —, F. Dobler. Fr. Pat. 349,930, May 20, 1904.

THE process described is for disinfecting beet pulp and sugar juices, and is based on the extraction of the sugar juice in presence of chlorides or hypochlorites, which are added to the cosettes or juice during diffusion in either a solid or dissolved state. —T. H. P.

Sugar Solutions; Continuous Boiling of — in Two Vacuum Pans for the Formation of Crystals. W. Witkiewicz. Fr. Pat. 351,836, Feb. 27, 1905.

THE continuous boiling of the sugar solution is effected

by distributing the heating surface between two vessels, the bottoms of which are connected by means of a pipe, and one of which serves for the preliminary, and the other for the final boiling. In both these vessels the heating is carried out, as far as is possible, by low-pressure steam. —T. H. P.

XVII.—BREWING, WINES, SPIRITS, Etc.

Beers; Percentage of Alcohol in German —, H. Woch. f. Brau., 1905, 22, 432-433.

REVIEWING the results of the analysis of several hundred samples of German beers examined during the last years, the author summarises the percentages of alcohol contained in the different types of beer. Out of 112 samples of bottom-fermentation beers from North and Central Germany, 79.7 per cent. of the pale beers contained 71.6 per cent. of the dark beers contained between 34.4 per cent. of alcohol by weight; the average alcohol content of the pale beers was 3.55 per cent., and of the dark beers 3.70 per cent. The 112 samples of top-fermentation beer examined are divided into six different classes. The proportion of alcohol in these varied considerably than in the case of the bottom-fermentation beers, but in nearly all of them it was comprised between the limits of 1 and 3 per cent. —J. F. B.

Alcohol, Ethyl; Spontaneous Oxidation of —, L. Mathieu. Bull. Assoc. Chim. Sucr. Dist., 1905, 22, 1283-1293.

IN wines or alcoholic solutions of the same strength, the alcohol is converted into aldehyde by simple contact with the air at the ordinary temperature, without the contact of porous bodies or the agency of micro-organisms. The action is markedly accelerated when the solution contains oxidisable bodies like sulphurous acid, ferrous sulphate, ferrous oxide, manganous oxide, &c., and also by exposure to sunlight. Green glass is less favourable to the oxidation than white glass. These conclusions confirm the experience of Roeser on the influence of aeration on the production of aldehyde in fermentation and show that account should be taken of the possible formation of this compound by simple contact with air. —L. J. DE W.

(C).—DISINFECTANTS.

ke; Antiseptic Properties of —. *Experiments in Disinfection by the Gases formed in Burning Sugar.* Trillat. Comptes rend., 1905, 141, 215–217.

AR heated to 105° C. gives off, after some hours, considerable amounts of formaldehyde, and as the temperature which it is heated is raised, the evolution of the aldehyde becomes more rapid. The gases from burnt sugar contain in percentages 0.2 to 5.7 of formaldehyde; 0.1 to 0.5 of ethyl alcohol; 0.1 to 5.0 of acetone; 1.0 to 3.0 of acetic acid; 1.0 to 3.0 of phenols and their derivatives; 0.5 to 1.0 of benzaldehyde. The formaldehyde is thus accompanied by substances which intensify its antiseptic action, either directly or by retarding its polymerisation. Direct experiment showed that by burning 10 kilos. of sugar (or better, 6 kilos. in two successive portions) in a room of 100 cb. m. content, even very resistant germs were destroyed. While this treatment is as efficient as that with formaldehyde itself, yet its simplicity and availability recommend it as a method of disinfecting likely to be of often of service.

Drum-Filter [for Waste from Paper Factories]. E. Füllner, Warmbrunn, Germany. U.S. Pat. 794,173, July 11, 1905.

A hollow drum is supported so that it can be rotated in a tank, in which the liquid to be filtered, such as waste water from paper manufactures, is contained. A number of separate filtering cells are arranged around the surface of the drum and covered with a filtering medium. Each cell is provided with a discharge tube to deliver the filtrate into the interior of the drum, these tubes being bent away from the interior surface of the drum, in the direction opposite to that in which it rotates, whilst each tube has a valve which opens during the descent and closes during the ascent of the cell. The deposit on the filter cloth is removed by a system of scrapers and rollers.

Nitrocellulose or Similar Substances; Making Compounds of —. D. Bachrach, Baltimore, Md. U.S. Pat. 794,581, July 11, 1905.

CLAIM is made for a non-inflammable or slow-burning compound of nitrocellulose, &c., produced by adding to the usual constituents non-aqueous ethyl, methyl and amyl silicates, and similar silicates known as silicic esters, and a free acid.—G. W. McD.

FRENCH PATENTS.

Lustré of Cellulose Threads [Artificial Silk]; Process for Increasing the —. R. Linkmeyer and M. Pollak. Fr. Pat. 350,889, Jan. 20, 1905. V., page 888.

Papier-maché Threads; Manufacture of —. M. Müller. Fr. Pat. 351,902, Feb. 28, 1905.

THE threads are first immersed for a short time in a bath of dextrin, starch, gelatin, or other glutinous substance, oil or soap being added when a supple product is required. As soon as the threads are impregnated they are immediately transferred to a machine where they are brushed with paraffin, fat, wax, &c., with the object of increasing their strength and resistance to moisture.—C. A. M.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

Lead in Pharmacopœial Chemicals; its Occurrence and Determination. C. A. Hill. Chem. and Drug., 1905, 66, 388–391.

THE method usually employed for determining the amount of lead in pharmacopœial chemicals, viz., the colorimetric

method was the one used, the modifications necessary in various cases being observed (see Warrington, this J., 1893, 97; Budden and Hardy, Analyst, 1894, 169, and Teed, Analyst, 1902, 142). In cases where the colorimetric method was not available (*e.g.*, in coloured solutions), incineration was resorted to with satisfactory results, providing the ash were present in sufficient quantity, and not reduced to a white ash, but treated with nitric acid and sulphuric acid, in order to avoid volatilisation of the lead. The electrolytic method, however, is preferred to this latter, the operation being carried out in presence of ammonium oxalate, and at a temperature of about 75° C.—T. F. B.

Formaldehyde, and Production of Formates. H. and A. Euler, Ber., 1905, 38, 2551—2560.

The formation of sodium or barium formate by the action of sodium or barium hydroxide on formaldehyde is a reaction of the second order, but proceeds practically according to the first order if large excess of the aldehyde be present. The reaction is not one of oxidation, as it takes place as readily in an atmosphere of hydrogen as in one of oxygen. Formate is produced much quicker by the action of calcium hydroxide than with sodium or barium hydroxide, and the reaction is evidently caused by the action of calcium hydroxide on a calcium-formaldehyde complex. The power of the different bases to condense formaldehyde to sugar bears no relation to the velocity of production of formate.—T. H. P.

Quinine Formates. H. Lacroix, J. Pharm. Chim., 1905, 22, 99—103.

THE normal salt, quinine diformate, crystallises in long white shining needles, readily soluble in water; this salt is unstable; it melts at about 95° C., and loses some of its formic acid at a temperature below 50° C.; its solutions have an acid reaction.

The basic salt, quinine monoformate, is prepared by combining quinine with the calculated quantity of formic acid in presence of water at 50° C. It crystallises in the anhydrous state as fine white silky needles, melting at 122° C. This salt appears to be one of the most convenient forms of the drug; it is very stable, and it is the richest in alkaloid of any of the usual quinine salts, containing 87.56 per cent. of quinine. Its solutions are neutral to litmus; it is soluble in water at 16° C. to the extent of 5.14 per cent., and is very soluble in boiling water. It is readily soluble in alcohol and chloroform, very sparingly soluble in ether and insoluble in vaseline and olive oil. The optical properties of aqueous solutions at 21° C. are $[\alpha]_D = -141.1$; index of refraction = 1.236; the solutions are non-fluorescent.—J. F. B.

Quinine Acid Hydrochloride; Note on —. W. Garsed, Brit. Pharm. Conf., Brighton, 1905. Pharm. J., 1905, 75, 138—139.

IN the B.P., the formula $C_{20}H_{24}N_2O_5 \cdot 2HCl \cdot 3H_2O$, is given for quinine acid hydrochloride, and it is required that (1) not more than 12 per cent. of water shall be lost at 100° C.; and (2) that not more than 2.5 c.c. of N/1 sodium hydroxide solution shall be required to completely neutralise one gram. of the alkaloid salt. Determinations of the moisture in five samples showed that the commercial quinine acid hydrochloride is practically an anhydrous salt. In the titration of the acid, the most satisfactory results were obtained by using N/10 or N/5 alkali with phenolphthalein for determining the total acid, and with litmus for determining the amount of acid hydrochloride, the titration being continued in the latter case until no shade of red was left. Of the five samples examined, three contained notable quantities (18.8, 19.8, and 46.5 per cent.) of the neutral hydrochloride.

—A. S.

Mercuric Zinc Cyanide. D. B. Dott, Brit. Pharm. Conf., Brighton, 1905. Pharm. J., 1905, 75, 136—137.

THE author discusses the composition of the so-called mercuric zinc cyanide (see Dunstan, this J., 1890, 211; 1892, 367), which is used to a considerable extent as an antiseptic in surgical dressings. Dunstan found that the

amount of mercuric cyanide contained in the prepared according to the quantity of water used in preparation, the maximum amount obtainable is 38.5 per cent. Since, however, some decomposition always occurs, the pure product would contain a somewhat larger proportion of mercuric cyanide, and from a number of experimental results, Dunstan concluded the proportion of mercuric cyanide in the pure product was 40.5 per cent., "a number which agrees almost exactly with the percentage (40.65) required by the formula $Zn_3Hg(CN)_{10}$." The author points out that the formula given by Dunstan requires not 40.65 but 35.0 per cent. mercuric cyanide, so that the argument based on number 40.5 is invalid. Further, variations of temperature, of the manner of mixing the mercury and solutions, of the time of contact of the water with precipitate, &c., all cause marked differences in the position of the product, and, until further evidence of the existence of a definite double cyanide of mercury and zinc is brought forward, the product should be simply "zinc and mercury cyanide," although it will be convenient to specify that it should contain a definite proportion of mercuric cyanide, say, 20 per cent.

ENGLISH PATENTS.

Tetrachlorethane [Acetylene Tetrachloride] and its Derivatives from Acetylene; Production of Symmetrical Compounds. H. K. Tompkins, Glasgow. Eng. Pat. 19,568, Sep. 1904.

THE explosive tendency of the reaction between acetylene and antimony pentachloride is due to the presence of excess of chlorine in the latter, and can be prevented by ensuring the presence of a certain proportion of antimony trichloride during the passage of the acetylene. The best yields are obtained by adjusting the quantity of acetylene so that the liquor at the end of the absorption has the composition $SbCl_5 \cdot C_2H_2 + SbCl_3 + xSbCl_3$. This liquor is distilled in small quantities at a temperature of 120° C. during the passage of the acetylene, in which case the acetylene tetrachloride is produced directly. Acetylene dichloride is produced together with the tetrachloride when the saturation of acetylene is carried to the point of completion. Tetrachlorethylene is prepared by the action of ammonia upon acetylene tetrachloride.—J. F. B.

Salicylglycollates; Manufacture of Crystallised Salicylglycollate and Ethyl —, and a Product for use in Therapeutics. O. Imray, London, from Soc. Chem. Ind., Basle, Switzerland. Eng. Pat. 24,672, Nov. 14, 1904.

SODIUM salicylate is heated with dry methyl chloracetate for 24 hours at a temperature of 160°—170° C. under a reflux condenser. After cooling, the dichloride is filtered off, and the product is purified by fractional distillation *in vacuo*. The methyl ester, m. pt. 29° C., and the ethyl ester, m. pt. 30° C., when mixed together in the form of the pure crystals, yield a product which is liquid at temperatures above 0° C. This mixture is claimed as a liquid therapeutic agent, suitable for external application.—J. F. B.

Alkylbarbituric Acids; Manufacture of —. O. Imray, London, from Farbwerke vorm. Meister, Lucius and Brüning, Höchst a/Main, Germany. Eng. Pat. 24,990, Nov. 17, 1904.

SEE U.S. Pat. 795,495 of 1905; following these.—J. F. B.

Camphor; Manufacture of —. Chem. Fab. Actien, vorm. E. Schering, Berlin. Eng. Pat. 25,590, May 5, 1905. Under Int. Conv., May 17, 1904.

THE vapours of isoborneol may be oxidised to camphor by means of oxygen or air, with or without the use of catalytic agents. Isoborneol (10 kilos.) is heated to 150° C., and gradually volatilised by passing a stream of oxygen over it; the resulting mixture of gases is passed over platinised asbestos heated to 150° C.; a mixture of

phor, camphene and isoborneol results, from which phor can be isolated by known methods. —T. F. B.

UNITED STATES PATENTS.

bon Tetrachloride; Process of Making — J. L. anziger, New York. Assignor to Castner Electrolytic alkali Co., Virginia. U.S. Pat. 794,789, July 18, 1905.

bon tetrachloride is produced by heating carbon plhide with twice the theoretical quantity of sulphur ride in presence of aluminium amalgam. —T. F. B.

bon Tetrachloride; Process of Purifying — J. L. anziger, New York. Assignor to Castner Electrolytic alkali Co., Virginia. U.S. Pat. 794,970, July 18, 1905.

bon tetrachloride containing carbon bisulphide is fied by digesting it with a solution of an alkali or line earth sulphide containing free alkali, thus separat- the bisulphide in the form of a thiocarbonate. The carbonate solution is subsequently decomposed into on bisulphide and hydrogen sulphide by addition of acid. —T. F. B.

lbarbituric Acids; Process of Making — A. nhorn, Munich. Assignor to Farbwerke vorm. Meister, eus and Brüning, Höchst-on-the-Maine, Germany. S. Pat. 795,495, July 25, 1905.

YLBARBITURIC acids are obtained by heating alkyl- namides with diaryl carbonic acid esters. Thus ylbarbituric acid may be produced by heating ylmalonamide with diphenylcarbonate for a con- able time at a temperature of 190 —250° C. —T. F. B.

FRENCH PATENT.

Glycerin; Process for Nitrating — Dynamit Act.-Ges. vorm. A. Nobel and Co. Fr. Pat. 351,454, Feb. 14, 1905.

THE waste acids from nitroglycerin manufacture usually contain so low a proportion of nitric acid that they are not regenerated, but denitrated. Claim is made for a method of regeneration whereby the yield of nitroglycerin is sensibly increased. 200 grms. of a fresh nitrating acid of the composition: sulphuric acid, 60 per cent.; nitric acid, 30 per cent.; water, 10 per cent., gives with 100 grms. of glycerin a yield of 201 grms. of nitroglycerin. If 450 grms. of spent acid from a previous nitration be mixed with the same weight of fresh acid so that the mixture has the composition indicated above, a yield of 228 grms. of nitroglycerin is obtained with this 900 grms. of acid from 100 grms. of glycerin. Acid which has been used and regenerated three times gives under similar conditions a yield of 226 grms. 1200 grms. of a regenerated acid of the composition: sulphuric acid 56.7 per cent., nitric acid 28.3 per cent., water 15.0 per cent. gives with 100 grms. of glycerin a yield of 218 grms. of nitroglycerin. It is also stated that the process of nitration is rendered less dangerous by the use of regenerated acids. —G. W. McD.

Nitroglycerin Explosives; Method for Preventing the Freezing of — Westfälisch-Anhaltische Sprengstoff Act.-Ges. Fr. Pat. 351,805, Feb. 25, 1905.

THE addition of from 15 per cent. to 25 per cent. of dinitromonochlorhydrin to nitroglycerin explosives is claimed in order to prevent freezing at low temperatures. For this purpose it is said to be superior to dinitroglycerol. There is no danger in manufacture, and the compound is very stable. —G. W. McD.

Safety Explosives [Chlorate and Perchlorate]; Method of Manufacture of — G. Grobet. Fr. Pat. 351,793, Feb. 24, 1905.

CLAIM is made for the use of volatile hydrocarbons (turpentine, benzene, petrol) in explosives of the chlorate type. Volatilisation of these bodies is prevented by mixing them with tallow and resin. The tallow is melted and is then mixed with an equal weight of a solution consisting of equal parts of colophony and petrol. From 8 to 12

parts of this mixture are incorporated with 80 parts of potassium chlorate at 40°–50° C. The explosive thus produced is plastic and of good keeping qualities.

G. W. McD.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS, &c.

ENGLISH PATENTS.

Gas, Acid and the like Fluids; Apparatus for Testing — J. Milne and H. O'Connor, Edinburgh. Eng. Pat. 15,885, July 18, 1904.

A pump of known capacity is connected with an absorption vessel, containing an absorbent which changes its colour or nature when acted upon by a certain quantity of gas or the like. This pump forces or draws the gas under examination through the absorbent. When the said change occurs, the volume of gas needed to produce the change is ascertained from the number of strokes made by the pump.—C. S.

Sulphuretted Hydrogen and other Gases; Apparatus for Generating — W. and J. George, Ltd., and A. J. George, all of London. Eng. Pat. 1816, Jan. 30, 1905.

The prism-shaped vessel *c* is charged to about two-thirds of its capacity with the acid or other fluid intended to act upon a solid (such as ferrous sulphide, for instance) placed in the removable, perforated tube *a*, capped by the valved delivery pipe *e*. When it is desired to arrest the production of gas, the vessel is set upon its base, *B*, whereby the portion containing the tube is left free from liquid, and the reaction ceases. The apparatus may be modified in various suggested ways.—E. S.

FRENCH PATENT.

Combustion Gases; Apparatus for the Determination of Carbon Dioxide in — A. Schlatter and L. Deutsch. Fr. Pat. 251,442, Feb. 11, 1905.

The principle of this apparatus depends upon the absorption of carbon dioxide by caustic potash or other agent. A measured volume of the gas is drawn from the furnace or chimney flue by means of a piston working in an air-tight cylinder, and is forced through the caustic potash

solution, contained in a suitable vessel. Another piston and cylinder of equal dimensions are connected with the liquid in the absorption vessel, and the reciprocal movement of this piston is arranged to keep the volume of gas and liquid in the absorption vessel at a constant value. As the first piston descends, the second rises, and draws from the absorption vessel a volume of caustic potash solution equal to the gas forced in. Both pistons are worked by mechanical means, and the apparatus is thus an automatic one. A pressure-gauge is attached to the base of the absorption vessel, and from the variation in pressure due to absorption, the percentage of carbon dioxide in the gases can be deduced.—J. B. C. K.

INORGANIC—QUALITATIVE.

Phosphatic Slags; Detection of Natural Phosphates in — L. Ledoux. Congrès Chim. Pharm. Liège, 1912, 129–134.

THE method consists in extracting the phosphate, first with citric acid, which dissolves all the phosphoric acid of the slag, and then with nitric acid. The latter extract only gives a precipitate with ammonium molybdate when mineral phosphates have been added to the slag.

The substance (3 grms.) in the form of an impalpable powder, is frequently shaken with 50 c.c. of 40 per cent. citric acid for half an hour, filtered and well washed with boiling water. The filter and its contents are then stirred for half an hour with 25 c.c. of the 40 per cent. citric acid, filtered and washed with boiling water. The residue is heated with a little nitric acid, and tested in the usual manner for phosphoric acid.

Results of experiments in which the process was applied to mixtures containing known amounts of mineral phosphates showed that the method is trustworthy.—N. H.

Vanadium Compounds; Behaviour of — towards Alkali and Solutions of Gold Compounds. F. Hundeshagen. XXIV., page 906.

INORGANIC—QUANTITATIVE.

Chlorates and Bromates; Volumetric Determination of — M. Scholtz. Arch. Pharm., 1905, 3, 353–358.

If a dilute aqueous solution of a chlorate be acidified with nitric acid, and a suitable quantity of sodium nitrate added, the chlorate is completely reduced to chloride in a short time, and as the solution contains free nitric acid, the chloride can be determined by precipitation with an excess of silver nitrate solution and titration of the excess of silver by Volhard's method with ammonium oxalate. The reduction of the chlorate is always complete after a quarter of an hour, and the presence of a small quantity of nitrous acid in the solution does not appreciably affect the accuracy of the titration with ammonium oxalate. Bromates can be reduced in an exactly similar manner and in a shorter time (five minutes), but iodates are not affected.—A. S.

Platinum and Iridium; Separation of — L. G. Hennrichsen. Chem. News, 1905, 92, 29–30.

FOR the determination of platinum in alloys containing iridium, the substance is dissolved in a mixture of nitric acid of sp. gr. 1.32 and 2 vols. of hydrochloric acid of sp. gr. 1.18. After carefully expelling the excess of nitric acid, the solution is heated to 120° C., water is added, and the metals precipitated by magnesium. The deposited metals are dried, ignited and heated to full redness in a current of hydrogen. After cooling the excess of magnesium is removed by extraction with sulphuric acid (1 in 10) and the residue treated with aqua regia diluted with three times its volume of water. The solution contains platinum but no iridium; the platinum is precipitated as the double ammonium chloride, and the precipitate ignited, preferably in the presence of a reducing agent, such as oxalic acid or dextrose. Still better, the charred filter paper. In carrying out this method the author found that the iridium precipitated by magnesium is soluble in dilute sulphuric acid.

tic acids, and is probably in the form of an oxide, precipitate while still moist, or after drying at 100° C., as a yellow solution gradually changing to violet with sulphuric acid, and a green solution with acetic acid. After being heated in air at 440° C., it dissolves sulphuric acid with a violet colour, and after heating 300° C., it gives a blue solution.—A. S.

Electrolytic Determination of — for Technical Purposes. K. Jene. Chem.-Zeit., 1905, 29, 803—804.

adaptation of the method devised by v. Foregger. In principle, the principle of which is the electrolysis of strong sodium hydroxide solution of the zinc, to ores, dusts, &c. The author's process is as follows:—A grm. of the substance is dissolved in *aqua regia*, the solution evaporated to dryness, 1—2 c.c. of 1:1 sulphuric acid added, and the mixture evaporated till white fumes appear. After cooling, the solution is diluted with water, heated to boiling, and the lead and insoluble matter filtered off. It is possible, with practice, to keep the filtrate and washings down to 100 c.c. Solid sodium hydroxide (4—7 grms.) is then added, and allowed to dissolve completely, the solution is heated to 50° C., and red into a coppered platinum basin for electrolysis (nickel basin may be used). The temperature is kept at 50° C. by a small burner, and the solution is electrolysed for 1½—2 hours, with a current of 1 ampère at 3—8 volts. The end is shown by hanging a small copper plate in the liquid in contact with the basin for some minutes, when no zinc should be deposited on it. The deposit is first washed without interrupting the current, with water and acid-free alcohol, dried in the air for a couple of minutes, and left in the desiccator for weighing. It may be advantageous to add from time to time a few drops of water to allow for evaporation, thus avoid exposure of the upper edge of the zinc deposit. The deposit can be removed by very dilute acetic acid without affecting the copper. Duplicate assays agree very closely, and the maximum difference between this method and the gravimetric (weighing as phos. in Rose crucible), in a large number of ores containing from 12 to 35 per cent. of zinc was 0.3 per cent. In an experiment, in which compounds of iron, aluminium and manganese were added to pure zinc sulphate, we find that the precipitated hydroxides do not interfere with the electrolysis.—J. T. D.

Found in Pharmacopoeial Chemicals; Occurrence and Determination. C. A. Hill. XX., page 901.

ORGANIC—QUALITATIVE.

Guaiacum Resin; Reactions of — [with Ferric Salts]. P. Petit and Mayer. Comptes rend., 1905, 141, 193—195.

When in hydrogen, guaiacum gives a blue colour with salts of ferric or manganic salts, or with silver salts; reaction to ferrous or manganous salt, or to metallic iron occurs. Ferrous chloride does not give the blue colour, which appears, however, if the liquid be exposed to air; manganous chloride does not give it even in absence of air, but addition of sodium hydroxide causes it to appear, or the substitution for manganous chloride of the lactate or acetate. Citric acid completely prevents the production of the colour by ferric salts. Tincture of guaiacum in an atmosphere of hydrogen dissolves ferrous, manganous and manganic oxides; the ferrous solution turns blue in the air, the manganous solution only in presence of acetic or acetic acid, the manganic solution if a trace of acid be added. When ferric oxide is dissolved in tincture of guaiacum, the blue colour is only produced if the solution be rich in alcohol or if a great deal of it be used. It seems as though there was a blue compound of ferric oxide and guaiacum, soluble in alcohol, but only slightly in water. The blue colouring matter, whether obtained with ferric, manganic, or silver salts, is soluble in alcohol, chloroform, but only slightly in benzene; the solutions on loss their colour. The sensitiveness of the reaction with all these salts is greatly reduced by the presence of albumin, and then depends on the acidity; the

addition of lactic acid diminishes the amount of ferric salt needed to produce a given depth of colour.—J. T. D.

ORGANIC—QUANTITATIVE.

Sugar; Influence of Invert Sugar on the Determination of Crystallisable —. M. Catimantand. Bull. Soc. Chim., 1905, 33, 795—799.

The author has found, contrary to the opinion expressed by A. Girard, Leplay and C. Baidy, that uncrystallisable sugar diminishes the rotatory power of crystallisable sugar with which it is mixed in low products and particularly in cane molasses, and that there is an analogy between the crystallisable sugar inverted by means of an organic acid and that contained normally in cane sugars. The method consists in preparing a syrup of invert sugar of known strength and mixing it with pure sugar syrup. The mixture is then subjected to examination by the polarimeter. The invert sugar is made by dissolving 5 grms. of tartaric acid in 500 c.c. of water, which is maintained at the boiling temperature, while 1 kilo. of sugar is dissolved in it and the heating continued for half an hour, the water evaporated being replaced by cold water. At the end of this time the inversion is complete. As in invert sugar produced with mineral acids, the rotatory power diminishes with increase of temperature. The inversion of pure sugar by tartaric acid is most rapid and complete when the solution is about 35°—36° B. It is slow with 10 per cent. solutions and nil with cane molasses containing a large proportion of invert sugar. A solution containing 20 grms. of sugar treated with 5 grms. of tartaric acid per litre on June 1st, at 20°—25° C., was completely inverted on Aug. 3rd. The proportion of uncrystallisable sugar in raw sugars being almost always below 5 per cent., the inversion with hydrochloric or tartaric acid is useless, since this quantity does not modify the rotation of sugar. On the contrary, when the proportion reaches 10 to 20 per cent., the Clerget method must be used, after defecation with basic acetate of lead.—L. J. DE W.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Radio-Activity; Further Notes on —. W. H. Martindale. Brit. Pharm. Conf., Brighton, 1905. Pharm. J., 1905, 75, 149—152.

AFTER reviewing recent work on radio-activity, the author draws attention to the desirability of paying more attention to the comparatively cheap radio-active uranium and thorium compounds. Commercial thorium hydroxide is usually very active, more so than the nitrate. The author has prepared the following organic salts of thorium:—Salicylate ($\text{HO.C}_6\text{H}_4\text{COO}$)₂ThO, cinnamate ($\text{C}_6\text{H}_5\text{CH:CH.CO}$)₂Th, orthocoumarate ($\text{HO.C}_6\text{H}_4\text{CH:CH.CO}$)₂Th, oleate, lactate, paraphenylsulphonate, camphorsulphonate, $\text{Th(C}_{10}\text{H}_{15}\text{O}_2\text{SO}_2)_4 \cdot 9\text{H}_2\text{O}$, glycerylphosphate, quinate and acid urate. The salicylate, cinnamate, orthocoumarate, glycerylphosphate and acid urate were prepared by double decomposition between thorium nitrate and the sodium salt of the acid in question; the other salts were obtained by the action of the acid on thorium hydroxide. The relative radio-activity of the different compounds is shown in the following table:—

	Scale Division.	Minutes.
Thorium lactate	3	3½
„ hydroxide (moist)	3	5
„ paraphenylsulphonate	3	6
„ salicylate	3	7
„ oleate	3	15
„ orthocoumarate	3	15
„ acid urate	3	16
„ cinnamate	3	19

—A. S.

Bromine in Solutions of Potassium Bromide. F. P. Worley. Chem. Soc. Trans., 1905, 87, 1107-1123.

THE author determined the solubility of bromine in aqueous solutions of potassium bromide over a wide range of concentrations at 18.5 and 26.5° C. For solutions containing less than 0.1 gram-mol. of potassium bromide per litre, the increased quantity of bromine dissolved over the corresponding amount for pure water was in the proportion of two atoms for every molecule of potassium bromide in solution. In these solutions, therefore, the bromine probably combines with the whole of the potassium bromide present to form the compound KBr_3 . With more concentrated solutions (up to 0.9 N) of potassium bromide, the proportion of bromine dissolved is slightly greater, probably owing to the formation of small quantities of more complex compounds than KBr_3 . The application of the principle of mass action to the case of solutions of potassium bromide containing varying amounts of bromine insufficient for saturation, gave results confirming those obtained by the solubility determinations.—A. S.

Vanadium Compounds; Behaviour of — towards Gold and Solutions of Gold Compounds. F. Hundeshagen. Chem.-Zentr., 1905, 29, 7394-840.

VANADIC acid and the compounds corresponding to it do not, under any circumstances, precipitate metallic gold from solutions of its compounds; on the other hand, they tend, in solutions containing hydrochloric acid or chlorides, to dissolve metallic gold, themselves becoming reduced to compounds derived from the tetroxide. So long as the solution remains acid, these last-named compounds exhibit no tendency to precipitate gold; but if it be made alkaline, the gold is precipitated as a grey-violet powder. Thus the reaction $3\text{VOCl}_3 + \text{Au} \rightleftharpoons 3\text{VOCl}_2 + \text{AuCl}_3$ proceeds from left to right in acid, from right to left in alkaline solution. Vanadium compounds corresponding to lower oxides than V_2O_5 act as powerful reducing agents towards gold solutions, and precipitate the metal from alkaline solutions immediately as a grey-violet powder, from acid solutions slowly in the cold, more rapidly on heating, as brilliant metallic scales. The frequent presence of vanadium compounds in association with gold suggests the possibility of these reactions having played a part in the formation of gold deposits. Selenic and telluric acids, though not chemically related to vanadic acid, appear to behave similarly to it in their relations to gold. A convenient qualitative test for vanadium in minerals consists in pouring strong hydrochloric acid on a porcelain plate or shallow basin, and dusting in a little of the powder; each granule of vanadium compound becomes surrounded with an orange-brown region of chloride, which gradually widens and then disappears.—J. T. D.

Aluminium Powder; Oxidation of —. Kohn-Abrest. Comptes rend., 1905, 141, 323-4.

ALUMINIUM powder, heated for 10 minutes in a tube open at both ends, shows no sign of oxidation unless the temperature be above 400° C. The rate of oxidation slowly increases as the temperature is raised to 625° C., and from that temperature to 750° C. is constant. Above 800° C. it increases again to 1000° C., from which temperature to 1200° C. there is no change in the rate. The metal begins to lose its lustre about 500° C. and gradually becomes greyer and less metallic-looking as the temperature rises. When heated for an hour at 1000° C. the weight of oxygen absorbed is a maximum, and amounts to 59 per cent. of the weight of the original metal. This corresponds very closely to the formula AlO . Indications of the oxides Al_2O_3 and Al_2O have also been obtained.—J. T. D.

Phosphorus Sub-iodide, and its Action in the Allotropic Transformation of Phosphorus. R. Boulouch. Comptes rend., 1905, 141, 256-258.

IF a solution of equal quantities of iodine and phosphorus in well-dried carbon bisulphide be exposed to sunlight, a red coloured sub-iodide of phosphorus, P_4I , is deposited. It is decomposed into the bi-iodide, P_2I_2 , and phosphorus on heating. Dilute nitric acid attacks it vigorously, liberating iodine. It dissolves easily in concentrated alkalis with evolution of phosphoretted hydrogen. If

treated first with cold dilute alkalis or alkali carbonates and then with hydrochloric acid, the yellow oxide of phosphorus $\text{P}_4(\text{OH})_4$ is produced. When the sub-iodide is treated with a solution of iodine, the bi-iodide and tri-iodide are formed. On heating, the yellow phosphorus formed reduces the bi-iodide to the sub-iodide, $7\text{P}(\text{yellow}) + \text{P}_2\text{I}_2 = 2\text{P}_4\text{I}$. The sub-iodide then decomposes into red phosphorus and the bi-iodide, which can then act on the yellow phosphorus $2\text{P}_4\text{I} - \text{P}_2\text{I}_2 + 7\text{P}(\text{red})$. Both actions are exothermic.—F. S.

Stannic Chloride and Bromide; Hydrolysis of — P. Pfeiffer. Ber., 1905, 38, 2466-2470.

THE author has succeeded in isolating the intermediate compounds SnCl_3OH and SnBr_3OH produced in the preparation of stannic acid by hydrolysis of the corresponding tin halides. A freshly-prepared 50 per cent solution of stannic chloride or bromide, is shaken with ether, the ethereal solution is dried with calcium chloride (only for a short time in the case of the bromine compound) and allowed to evaporate. The residue is purified by dissolving it in ether and adding petroleum spirit (ligroin) when the product soon separates in transparent colourless crystals of the composition $\text{SnCl}_3(\text{or Br}_3)\text{OH} + \text{H}_2\text{O} + (\text{C}_2\text{H}_5)_2\text{O}$. These compounds are analogous to those formed by alcoholysis of stannic chloride or bromide $\text{SnCl}_3\text{OC}_2\text{H}_5 + \text{C}_2\text{H}_5\text{OH}$ and $\text{SnBr}_3\text{OC}_2\text{H}_5 + \text{C}_2\text{H}_5\text{OH}$ respectively, and as stannic chloride is a non-electrolyte in alcohol exerts only a very small electrolytic dissociation power, it follows that the alcoholysis and also the hydrolysis of stannic chloride (or bromide) are purely chemical processes in which ionic reactions have no part.—A. S.

Carbon; New Allotropic Form of — and its Heat of Combustion. W. G. Mixter. Amer. J. Scienc. Silliman, 1905, 19, 434-444. Chem. Centr., 1905, 2, 98-99.

THE carbon formed by the incomplete combustion of acetylene is dull and porous. It is a good conductor of heat and electricity. One gram. of it is capable of condensing one mgrm. of dry air on its surface and in its pores, but exercises no catalytic effect on gas reactions. It has a sp. gr. 1.919 at the ordinary temperature, and the heat of combustion at constant pressure and volume at 20° is 7894 cal. for 1 gram. or 94,728 cal. for 12 grms. Its heat of combustion is thus almost the same as that of graphite but the author confirms Moissan's statement that it does not contain graphite.—A. S.

Disaccharide; Synthesis of an Octamethylated — from Dextrose, Methylation of Sucrose and Maltose. Purdie and J. C. Irvine. Chem. Soc. Trans., 1905, 1022-1030.

THE alkyl ethers of the sugars which the authors have recently prepared (see this J., 1903, 888) appear to be well adapted for the synthesis of disaccharides by direct condensation. By the use of tetramethyldextrose, for instance, the problem of the constitution of the resulting disaccharide is greatly simplified, since there is but one hydroxyl group in each molecule of the alkyl ether, and whether this alkyl derivative exists in the glucosidic or aldehydic form, the position of the hydroxyl group is known. In the direct condensation of the alkyl ether of the sugar, the possibility of an "acetal union" of the molecules is precluded, and the condensation product must have one of the following three formulae, according as the two uniting molecules assume (I.) the γ -oxide, (II.) the aldehydic form, or (III.) one molecule, γ -oxide, and the second the aldehydic form:—

On heating a solution of tetramethyldextrose in benzene containing 0.33 per cent. of hydrochloric acid in a sealed be at 105°—115° C., water was separated, the rotatory power of the solution gradually increased, and the cupric-reducing power almost entirely disappeared. The syrup obtained from the solution was purified by distillation under reduced pressure, the octamethylated saccharide produced distilling at 180—190° C. at mm. pressure. Analysis of the compound showed it to be an octamethylidextrose anhydride. It had a specific optical rotation of 135.9° in methyl alcoholic solution, and had practically no action on hot Fehling's solution, was readily hydrolysed by dilute hydrochloric acid with production of tetramethyldextrose. The ease with which the compound is hydrolysed by dilute acid and the presence of cupric-reducing power indicate that the constitution of the compound is best represented by Formula 1.

This formula may represent three stereoisomeric forms, namely, the $\alpha\alpha$ -, $\beta\beta$ - and $\alpha\beta$ -modifications, since each of the glucoside groups can exist in the so-called α - and β -forms. The authors' product is probably a mixture of the three modifications.

Further experiments on the methylation of sucrose by the method previously described (*loc. cit.*) confirmed the view that the product obtained is an octamethylsucrose, which on hydrolysis yields a mixture of the tetramethyl compounds of dextrose and levulose, although the pure compounds, except tetramethyldextrose, were not isolated.

By the methylation of maltose, a neutral, rather viscous liquid devoid of cupric-reducing power was obtained. It is probable that the free aldehydic group in maltose is oxidised by the silver oxide during the methylation, and is subsequently methylated. From the products of hydrolysis of the methylated compound by dilute hydrochloric or sulphuric acid, tetramethyldextrose was isolated, and this serves to confirm the correctness of Fischer's formula for maltose.

fermentation; Lactic and Alcoholic — in the *Tissues of Plants, and Enzymes which cause this Fermentation*. By F. Stocklasa. Congrès Chim. Pharm. Liège, 1905, 35—141.

The enzymes obtained from mangolds and potatoes when led to sterilised solutions of glucose, gave rise to lactic acid alcoholic fermentation. The amounts of lactic acid, carbon dioxide, alcohol and acetic acid produced, were determined, and are given in a table. Formic acid and hydrogen are also produced.

In the breaking down of glucose, carbon dioxide is eliminated with production of lactic acid, after which methyl alcohol, acetic acid, methane and formic acid are produced, along with carbon dioxide and hydrogen, the hydrogen being oxidised to water. The fermentation is due to the enzymes alone, without co-operation of bacteria. —N. H. J. M.

Quebracho Tannin. M. Nierenstein. Collegium, 1905, 69—71.

Quebracho (*Loxopterygenium Lorenzii*, Sr.) contains, besides ellagic and gallic acids, about 20 per cent. of a valuable tannin substance of the catechol series. From the results of an examination of this tannin substance, the author concludes that it probably consists of a mixture of three catechol-tannins having protocatechuic acid as a common component. One gram. of the tannin substance was fused at 210°—220° C. with 5 grms. of caustic potash for 35 minutes. The product was neutralised with sulphuric acid, and, after filtering, extracted with ether. The residue left, after evaporating the ether, was dissolved in a little hot water, treated with dilute acetic acid, the precipitate decomposed with dilute sulphuric acid, and the solution extracted with ether. The residue left, after expelling the ether, was dissolved in water and the solution allowed to crystallise, when small needles of protocatechuic acid were obtained. The

red solution was extracted with ether, the ether solution evaporated and the residue dissolved in water. In the solution the presence of phloroglucinol was detected. After some time, crystals separated, which after recrystallisation from benzene were identified as resorcinol. Quinol (hydroquinone) was probably also among the decomposition products formed on fusion with caustic potash. An attempt was next made to separate the different constituents of the quebracho tannin by means of their bromine derivatives. Ten grms. of the tannin were dissolved in three litres of water and the colouring matter was precipitated by 25 c.c. of a 30 per cent. solution of lead acetate. To the filtrate, bromine water was added, drop by drop, and, after standing for 24 hours, the precipitated bromine compound was collected and purified by crystallisation from a mixture of one part of acetone and two parts of alcohol. The compound had a composition corresponding to the formula $\text{C}_{16}\text{H}_{14}\text{BrO}_4$ and contained two methoxyl groups. One gram. of the bromine compound was dissolved in 30 c.c. of alcohol and boiled for five hours under a reflux condenser with 7.5 grms. of caustic potash dissolved in 50 c.c. of alcohol. The alcohol was then expelled by steam, the solution neutralised with dilute sulphuric acid, and extracted with ether. The ether solution was evaporated, the residue dissolved in a small quantity of water, and the solution treated with lead acetate. The precipitate was decomposed by sulphuric acid, the solution extracted with ether, and the ether solution evaporated. The residue, after crystallising from water, was separated into two portions by treatment with chloroform, the insoluble portion being free from bromine and consisting of isovanillic acid, whilst the solution contained the monobromo derivative of an acid which the author terms *quebrachylic acid*. Monobromoquebrachylic acid, $\text{C}_8\text{H}_7\text{BrO}_4$, crystallises from chloroform in small needles, melting at 119—120° C., soluble in sodium carbonate solution, and giving no coloration with ferric chloride. When fused with caustic potash it yields monobromoresorcinol. —A. S.

New Books.

A SYNOPSIS OF THE PRINCIPAL CHANGES IN THE UNITED STATES PHARMACOPOEIA EFFECTED BY THE 8TH DECENNIAL REVISION, 1900—official from September 1st, 1905, compared with that of 1890, and the British Pharmacopoeia, 1898. By W. HARRISON MARTINDALE, Ph.D. H. K. Lewis, 136, Gower Street, London, W.C. Price, 2s.; post free, 2s. 1d.

Crown 8vo pamphlet with preface, three pages, and text filling 36 pages.

METHODS OF CHEMICAL CONTROL IN CANE SUGAR FACTORIES. By H. C. PRINSEN GEERLIGS, Director of the West Java Sugar Experiment Station, Pekalongan, Java. Norman Rodger, Altrincham, Manchester. 1905. Price 3s. 6d. net.

8vo volume containing preface and text with numerous tables, filling 86 pages. The scheme of the work will appear from the following headings:—I. DAILY REPORT. Analytical Methods. (i) Cane. (ii) Bagasse. (iii) First and last Mill Juice. (iv) Mixed Juice. (v) Clarified Juice and Filter Press Juice. (vi) Filter Press Cakes. (vii) Syrup. (viii) Masseccutes. (ix) First Molasses. (x) Exhausted Molasses. (xi) Sugar. Calculations. II. MONTHLY REPORT. Analysis. III. FINAL ACCOUNT OF SUCROSE EXTRACTED AND LOST. Laboratory Requirements. IV. TABLES. V. MODELS OF BOOKS (to be kept). VI. PLATE AS TABLE FOR THE QUOTIENT OF PURITY OF MASSECCUTES AND MOLASSES.

ON SILK AND THE SILKWORM. M. ARBOUSSET. Translated by ELIZABETH WARDLE, and Edited by her Father, Sir THOMAS WARDLE, President of the Silk Association of Great Britain and Ireland. W. H. Eaton, The Moorlands Press, Derby Street, Leek. 1905. Price, 2s. 6d. net.

SMALL 8vo volume containing frontispiece portrait of Laurent de l'Arbousset. Preface by Sir Thos. Wardle, and 283 pages of subject matter, with a table of contents as index. The work is a practical treatise on sericulture.

MONOGRAPHIEN UEBER ANGEWANDTE ELEKTROCHEMIE. Bd. XIX. I. DIE ELEKTROLYTISCHE CHLORAT-INDUSTRIE. VON JOHN B. C. KERSHAW. INS DEUTSCHE UEBETRAGEN VON DR. MAX HUTH, Chemiker der Siemens und Halske A.-G., Berlin. Wilhelm Knapp's Verlag. Halle a. S. 1905. Price, M. 6.

8vo volume containing preface by the author, and 123 pages of subject matter, illustrated with 39 engravings. The subject is subdivided as follows:—I. Historic review. II. Chemical and electrochemical phenomena in the Electrolytic preparation of Chlorates. III. Processes and Apparatus employed in the Manufacture of Chlorate, &c. IV. The Crystallising Process, Properties and Employment of Chlorate. V. Production, Yield, Costs. VI. Preparation of Sodium Chlorate, Perchlorates, Bromates and Iodates by electrolysis. VII. Analysis of the Chlorate liquors and Final Products.

ELEKTROLYTISCHE VERZINKUNG. VON SHERRARD COWPER-COLES. INS DEUTSCHE UEBETRAGEN VON DR. EMIL ABEL. Wilhelm Knapp's Verlag, Halle a. S. 1905. Price, M. 2.

8vo volume, containing 37 pages of subject matter, with 36 illustrations. The subject is subdivided as follows:—I. Introduction. II. Preparing of the metal for zinc plating. III. Arrangement, &c., of the Electrolytic cells, and the Electrolysis.

INDEX TO REPORTS OF H.M. DIPLOMATIC AND CONSULAR REPRESENTATIVES ABROAD ON TRADE AND SUBJECTS OF GENERAL INTEREST (WITH APPENDIX). 1904. [Cd. 2578.] Price 1s. 3d. Wyman and Sons, Fetter Lane, E.C.

The index, which is a volume of 292 8vo pp., covers the various consular reports issued by the Foreign Office during 1904. It concludes with an appendix giving a list of the Reports and the price of each.

ANNUAL STATEMENT OF THE TRADE OF THE UNITED KINGDOM WITH FOREIGN COUNTRIES AND BRITISH POSSESSIONS, 1904. Vol. II. [Cd. 2626.] Price, 4s. 3d.

This is the second volume of the Annual Statement of Trade, the first volume having been noticed on p. 526 of the *Board of Trade Journal* of the 15th June. This volume contains statements of the trade of the United Kingdom with each foreign country and British Possession

during the years 1900—04, and of the imports and exports at each British port during the same period, as well as accounts of transshipment, warehousing, and goods passing in transit.

ROYAL COMMISSION ON COAL SUPPLIES.

FIRST REPORT OF THE ROYAL COMMISSION ON COAL SUPPLIES. Vol. II. MINUTES OF EVIDENCE AND APPENDIX. 1903. Price, 3s.

CONTAINS Table of Contents, List of Witnesses, Question Addressed to Witnesses on the Limit of Depth in Mining with list of Witnesses who gave evidence thereon; List of Questions on the Minimum Thickness of Workable Seam of Coal, and list of Witnesses thereon; Lists of Question on Waste in Working, and Witnesses thereon. Subject matter (evidence given) filling 344 pages, and Alphabetical Index.

SECOND REPORT OF THE ROYAL COMMISSION ON COAL SUPPLIES. Vol. I. THE REPORT, 1904. Price, 1d.

Royal Warrant, Appointment of Additional Commissioner and Report, 3 pages.

SECOND REPORT OF THE ROYAL COMMISSION ON COAL SUPPLIES. Vol. II. MINUTES OF EVIDENCE AND APPENDICES. Printed for His Majesty's Stationery Office by Wyman and Sons, Ltd., Fetter Lane, London E.C., 1904. Price, 3s. 5d. Eyre and Spottiswood East Harding Street, Fleet Street, E.C. Oliver at Boyd, Edinburgh, or E. Ponsenby, 116, Grafton Street Dublin.

This Report contains (1) List of Witnesses examined (2) Scheme adopted by the Commission for dealing with the question of possible economies; (3) Minutes of Evidence, filling 367 pages; and seven Appendices, follows:—I. List of Witnesses. II. Letter from Board of Agriculture and Fisheries with reference to the possible effect of increased production upon the price of Ammonium Sulphate. III. Memorandum by Mr. Bennett H. Brown on the Use of Blast Furnace Gas. IV. Analysis Natural Gas at Heathfield, Sussex, by Prof. H. B. Dix and Dr. W. A. Bone. V. Report on the Cost of Runni Producer Gas Plant at Messrs. Cadbury's Works, Bourneville. VI. Briquettes. VII. Peat. The volume ends with an Alphabetical Index of Subjects.

Trade Report.

I.—GENERAL.

MEXICO: CUSTOMS TARIFF OF —.

Bd. of Trade J., Aug. 3 and 10, 1905.

The following is a list of some of the items in the Customs Tariff of Mexico:—

No.	Articles.	Unit.	Duty
14	Animal fats, not specified	Kilo. gross.	Pesos. ct 0 0
28	Hides and skins, untanned, not specified	100 kilos. gross	3 6
46	Animal wax	Kilo. net	0 5
47	Glue	Kilo. gross	0 0
51	Stearine in cakes	Kilo. gross	0 1
52	Glycerin	—	Free
62	Calf skins, patent leather, kid skins, chamois and other common skins tanned, not specified	Kilo. legal	1 6
68	Sole leather	Kilo. legal	1 0
82	Candles of wax	Kilo. gross	0 7
83	Candles of spermaceti, stearine, and of tallow, pressed or not	Kilo. gross	0 2
107	Oleaginous seeds and fruits, not specified	Kilo. gross	0 0
125	Sugar, common, candy sugar, and refined sugar of all kinds	100 kilos. gross	2 5
134	Gums, resins and natural balsams, not specified	Kilo. legal	0 1
136	Cocoa-nut oil, linseed oil, maize and cottonseed oil, in ship tanks or cart tanks	100 kilos. net	0 0
137	Cocoa-nut oil, linseed oil, maize and cottonseed oil, in drums or tins	Kilo. gross	0 1
140	Oil of turpentine and turpentine	Kilo. legal	0 0
141	Vegetable tar and colophony	Kilo. gross	0 0
141	Gum arabic, copal, damar, pounce or sandarac, lac, senegal and tragacanth	Kilo. legal	0 1

	Articles.	Unit.	Duty.
1	Gold, silver or platinum in ores, in bullion for coining or in dust	Free	Free
5	Bronze, brass and white metal, in ingots or granulated	Kilo, gross	0 05
6	Copper in ingots or granulated, ores of copper, unwrought, and copper matte	Free	Free
7	Copper, brass, bronze and white metal, in bars	Kilo, gross	0 11
7	Tin in bars or in the rough	Kilo, legal	0 10
8	Ingots and alloys of lead and antimony, for printing type	Free	Free
0	Lead in bars, pigs or ingots	Kilo, gross	0 01
1	Zinc in ingots, filings, granulated or wire	Free	Free
2	Manufactures of tin, zinc, and of alloys of zinc, lead and tin, not specified	Kilo, legal	0 20
3	Manufactures of lead, not specified	Kilo, legal	0 10
3	Ferromanganese, containing 25 per cent. or more of manganese	100 kilos, gross	1 50
4	Asbestos in fibre or powder, emery in powder or lumps, marble or alabaster, in the rough or in powder, pumice stone, lava in the rough, gypsum and stucco	Kilo, gross	0 01
5	Clay, sand or moulding sand, fire clay, rottenstone, and tripoli	Free	Free
5	Jet, unwrought	Kilo, legal	0 25
7	Sulphur	Free	Free
7	Lime, hydraulic lime, cement (Roman or Portland), and carbonate of lime or Spanish white	100 kilos, gross	0 55
8	Coal	Free	Free
8	Carbonates of lime, of barytes, or of strontia, and peroxide of manganese	100 kilos, gross	3 30
9	Spar	Kilo, gross	0 10
9	Marble and alabaster sawn into slabs, not polished	Kilo, gross	0 05
1	Mineral stone of all kinds	Free	Free
1	Plumbago	Kilo, gross	0 06
1	Talc	Kilo, legal	0 04
1	Mineral oil, unrefined	100 kilos, net	3 30
1	Mineral oil, refined, benzine, mineral wax, and paraffin	Kilo, legal	0 09
1	Coal tar and asphalt	Kilo, gross	0 01
1	Coke	Free	Free
1	Vaseline	Kilo, gross	0 11
1	Paving stones and slabs	Free	Free
1	Manufactures of earthenware, cement, and lava, not specified	Kilo, gross	0 05
1	Paraffin candles	Kilo, gross	0 20
1	Crayon and chalk	Kilo, legal	0 15
1	Bricks, slabs, tiles, ridge tiles, ventilators, and tubes of earthenware	Thousand	2 75
1	Slabs of cement or artificial stone, even with coloured designs	Kilo, gross	0 01

V.—TEXTILES, YARNS, AND FIBRES.

SILK; EXCESSIVE WEIGHTING OF —.
U.S. Cons. Rep. No. 2312, July 19, 1905.

Japanese Government has adopted stringent regulations to prevent the continuance of excessive weighting, and recently issued an order on the subject, referring particularly to the silk fabric known as "habutai," quantities of which are exported from Japan. The regulations are as follows:—
The weight of habutai intended for export must not be used by dampening. In the manufacture of habutai of the following articles may be used: Magnesium, sugar. The minister of commerce and industry is required to extend this list of prohibited materials. Manufactured contrary to these regulations may be sold, transferred, or exported. The manufacturer attach to every piece a label bearing the name of the factor, where and when made, giving the year, month, and day, also the number of the piece. Each factor is required to keep a record of every piece received, giving the year, month, and day of delivery, of piece, and weight of the unfinished habutai, of year, month, and day when finished, the weight of habutai after the process of finishing, and the value of the goods when offered for sale. Each book be kept at least a year after the last entry in it has been made. The firms engaged in the export of habutai are required to submit their books and stock to the inspection of officers authorised for that duty. Whoever violates any of these regulations or makes false entries in his books will be punished by a fine of at least 25 yen (dols.). The proprietor of an establishment will be responsible for the acts of his agents or employees.

X.—METALLURGY.

FIG IRON PRODUCTION IN AMERICA.
Eng. and Mining J., Aug. 5, 216.
The production of bituminous coal and coke pig iron in the first six months of 1905 was 10,162,488 gross tons; of anthracite and coke mixed, 815,028 tons; of anthracite, 15,147 tons; of charcoal iron, 170,512 tons.
The production of spiegeleisen ferro-manganese, ferro-phosphorus, and ferro-bessemer in the first half of 1905 was 29,040 gross tons, against 105,882 tons in the last half of 1904 and 114,510 tons in the first half of 1904.

The production of ferro-manganese alone in the first half of 1905 amounted to 35,221 tons, against 30,535 tons in the last half of 1904 and 26,541 tons in the first half of that year. The production of spiegeleisen alone in the first half of 1905 amounted to 90,113 tons, against 74,705 tons in the last half of 1904 and 87,665 tons in the first half of that year. The production of ferro-phosphorus in the first half of 1905 amounted to 1206 tons, against 612 tons in the last half of 1904 and 304 tons in the first half. In the first half of 1905 there were made 2,500 tons of ferro-bessemer pig iron, but in neither half of 1904 was iron of that character reported to the association.

The whole number of furnaces in blast on June 30, 1905, was 294, against 261 on Dec. 31, 1904, and 216 on June 30, 1904. The number of furnaces idle on June 30, 1905, was 138. Of the active furnaces on June 30, 1905, 229 used bituminous fuel, 39 used anthracite coal and coke mixed, three used anthracite coal alone, and 23 used charcoal alone.

During the first six months of 1905 the number of furnaces actually in blast during a part or the whole of the period was 334, as compared with 297 during the last half of 1904 and 295 during the first half of that year.

On June 30, 1905, there were 11 furnaces in course of construction, of which 10 will use bituminous fuel when completed and one will use charcoal. Of the bituminous furnaces two are being built in New York, two in Pennsylvania, one in Virginia, one in Tennessee, one in Alabama, two in Ohio, and one in Colorado. The charcoal furnace is being built in Michigan.

LEAD; PRODUCTION OF—IN BRITISH COLUMBIA.

U.S. Cons. Rep. No. 2318, July 26, 1905.

The total production of lead in British Columbia for the fiscal year ending June 30, 1905, is 27,871 tons. For the year 1904 the production was 18,323 tons; 1903, 9044; 1902, 11,268; 1901, 25,791; 1900, 31,674. The figures tell of an industry which had dwindled to less than one-third of its top production in three years and which, in two years more, through the bounty, has almost regained its old position.

Of the 27,871 tons produced this year, 11,000 tons have been exported, while the remainder, nearly 17,000 tons, has been smelted in British Columbia. The rate of bounty paid varies with the London price, and is less for exported lead than for that treated locally, viz., 10 dols. a ton in the first case, 15 dols. in the second. The value of the total production of lead in British Columbia in 1904

amounts to 1,421,374 dols., while the combined product of lead in all the other Provinces of Canada is given as 215,346 dols.

XII.—FATS, FATTY OILS, Etc.

OLIVE OIL AT MALAGA, SPAIN.

For. Off. Ann. Series, No. 3458.

The quantity of olive oil shipped from Malaga during 1904 was greater than in any previous year since 1898. This is attributable to the poor crops experienced in all oil-producing countries, with the exception of Spain, where the yield was good both as regards quantity and quality. The oil shipped from this port is used chiefly for manufacturing purposes, being shipped to the United Kingdom, all European countries and the United States.

There is an increasing demand for olive oil foots (*aciete de orujo*), that is oil obtained by the treatment of the *orujo* or remains of the olives after the oil has been expressed by the ordinary processes. The oil produced here is said to be superior to that placed on the market hitherto, being almost neutral and free from sulphurous odour. The oil, which is used principally in the manufacture of soap, finds its chief market in the United States, the demand from there being alone three times as great as the present production of the whole of Andalusia. Germany also takes considerable quantities, but very little is exported to the United Kingdom, where other fats seem to have the preference in connection with the manufacture of soaps.

XVII.—BREWING, WINES, SPIRITS, Etc.

DUTY FREE SPIRITS.

Inland Revenue Report, Aug., 1905.

The amount of spirits used free of duty in connection with arts and manufactures under the Finance Act, 1902, increased considerably during the year 1904-5, as the following table shows:—

Year ended March 31.	Use.	Spirit.
		Proof galls.
1902-03	Arts and Manufactures	341
	Scientific (Universities, Hospitals, &c.)	358
		699
1903-04	Arts and Manufactures	206,452
	Scientific (Universities, Hospitals, &c.)	2,272
		208,724
1904-05	Arts and Manufactures	267,706
	Scientific (Universities, Hospitals, &c.)	2,680
		270,386

Patent List.

N.B.—In these lists, [A.] means "Application for Patent," and [C.S.] "Complete Specification Accepted."

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

- [A.] 15,781. Beynon. Machinery for pulverising, crushing and the like. Aug. 2.
- " 15,808. Wüstenhöfer. Disintegrating mills.* Aug. 2.

- [A.] 15,818. Le Maitre. Manufacture of agglomerates, paint material, fuel, briquettes and the like. Aug. 2.
- " 15,828. Radford (Currie). Filter presses. Aug. 2.
- " 15,838. Sieurin. *See under II.*
- " 15,932. Hunter. Method of and means for treating or purifying certain liquids or substances. Aug. 3.
- " 16,035. Hargreaves. Heating and evaporating solutions and apparatus therefor. Aug. 5.
- " 16,087. Hausmann. Crucible furnaces.* Aug. 1.
- " 16,144. Nicholas. Rotary filtering apparatus for the separation of liquids or solutions from tailing slimes, sewage, and the like. Aug. 8.
- [C.S.] 17,097 (1904). Wills. Furnaces. Aug. 10.
- " 17,098 (1904). Wills. Furnaces. Aug. 10.
- " 17,435 (1904). Heymann, Hey, Smith, Mitehe and Askham. Apparatus for separating and condensing the vapours of volatile liquid. Aug. 16.
- " 17,437 (1904). Heymann and others. Method of plant for removing grease and other impurities from woollen and other materials. Aug. 16.
- " 18,488 (1904). Lennox. Evaporators, also applicable for smoke washing. Aug. 16.
- " 18,922 (1904). Komata Reefs Gold Mining Co. (Brown). Apparatus for mixing or circulating materials in a liquid or semi-liquid state. Aug. 10.
- " 21,644 (1904). Howatson and Boby. Filter. Aug. 10.
- " 6235 (1905). Zagst. Temperature alarm for liquids. Aug. 10.
- " 10,947 (1905). Sauerbrey. Vacuum evaporator with heating and evaporation in separate chambers. Aug. 10.

II.—FUEL, GAS, AND LIGHT.

- [A.] 15,818. Le Maitre. *See under I.*
- " 15,838. Sieurin. Rotary kilns for generation of gas, roasting and the like. Aug. 2.
- " 15,907. Sumner. Liquid fuels. Aug. 3.
- " 15,961. Adcock. *See under XII.*
- " 16,018. Reeser. Incandescence bodies and method of making the same. Aug. 4.
- " 16,050. Davis. Apparatus for generating gas from gasoline. [U.S. Appl., Aug. 8, 1904.]* Aug. 10.
- " 16,182. Soc. Anon. des Combustibles Industriels. Oxidation of hydrocarbons. [Fr. Appl., Dec. 1904.]* Aug. 8.
- " 16,298. Forbes. Prepared carbides for acetylene lamps, generators and the like. Aug. 10.
- " 16,386. Koppers. Treatment of gases obtained from dry distillation or gasification of fuel. Aug. 11.
- [C.S.] 18,488 (1904). Lennox. *See under I.*
- " 20,138 (1904). Galloway. Absorbent non-combustible material for burning hydrocarbon and other liquid fuels. Aug. 16.
- " 3245 (1905). Schmidt and Desgray. Producer gas furnaces. Aug. 10.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

- [C.S.] 15,446. Brunck. *See under VII.*

IV.—COLOURING MATTERS AND DYESTUFFS.

- [A.] 15,763. Johnson (Badische Anilin und Soda Fabrik). Manufacture of intermediate compounds and colouring matters containing sulphur. Aug. 2.

- [A.] 16,012. Deutsche Gold- und Silber-Scheide-Anstalt, vorm. Rössler. Manufacture of indigo leuco bodies. [Ger. Appl., Aug. 13, 1904.]* Aug. 4.
- " 16,227. Inray (Farbw. vorm. Meister, Lucius and Brüning). Manufacture of blue colouring matters of the quinoline group and photographic surfaces sensitised therewith. Aug. 9.

- [C.S.] 21,638 (1904). Johnson (Badische Anilin und Soda Fabrik). Manufacture of azo colouring matters and of intermediate products. Aug. 10.
- " 22,735 (1904). Johnson (Badische Anilin und Soda Fabrik). Manufacture and production of azo colouring matter. Aug. 16.
- " 23,198 (1904). Johnson (Badische Anilin und Soda Fabrik). Manufacture and production of rhodamine colouring matters and of intermediate products relating thereto. Aug. 16.
- " 853 (1905). Johnson (Badische Anilin und Soda Fabrik). Manufacture of a new compound and of colouring matters therefrom. Aug. 10.
- " 1675 (1905). Newton (Bayer and Co.). Manufacture of azo dyestuff and of intermediate products. Aug. 10.
- " 1818 (1905). Johnson (Badische Anilin und Soda Fabrik). Manufacture and production of colouring matters of anthracene series. Aug. 16.
- " 2228 (1905). Shillito (Aniline Colour and Extract Works, formerly J. R. Geigy). Manufacture of azo colouring matters. Aug. 10.

V.—PREPARING, BLEACHING, DYEING, RINTING AND FINISHING TEXTILES, YARNS, AND FIBRES.

- [A.] 16,159. Quackenbos. Process for cleaning wool and recovering the elements.* Aug. 8.
- [S.] 17,437 (1904). Heymann and others. *See under I.*
- " 18,056 (1904). Rhodes. Apparatus for dyeing and otherwise treating with liquids, wool, yarn, and other fibrous materials. Aug. 10.
- " 18,488 (1904). Lennox. *See under I.*
- " 8160 (1905). Blanck. Finishing machine for textile and like fabrics. Aug. 10.
- " 12,246 (1905). Moore. Sheets of embossed fibrous material and method of making same. Aug. 10.
- " 12,247 (1905). Moore. Apparatus for forming designs on opposite surfaces of a sheet of fibrous material. Aug. 10.

I.—COLOURING WOOD, PAPER, LEATHER, ETC.

- [A.] 16,316. Kornmann. Method of colouring wood.* Aug. 10.
- " 16,327. Davies and Ewing. Means for use in applying colour to woven fabrics or colour or paint to other surfaces. Aug. 11.

VII.—ACIDS, ALKALIS, AND SALTS.

- [A.] 15,646. Brunck. Extraction of ammonia from distillation gases.* July 31.
- " 15,747. Latham. *See under IX.*
- " 16,035. Hargreaves. *See under IX.*
- [S.] 20,241 (1904). Fryklind. Process of producing ammonia or ammonium salts from nitrogenous organic substances containing a high percentage of water. Aug. 10.
- " 22,323 (1904). Johnson (Badische Anilin und Soda Fabrik). Manufacture and production of stable hydrosulphites. Aug. 16.

- [C.S.] 22,540 (1904). Johnson (Badische Anilin und Soda Fabrik). Production of toxic gas poisoning compounds. Aug. 16.
- " 6693 (1905). Fölling. Pressing of thin blocks of silicon or carbon. Aug. 10.

VIII.—GLASS, POTTERY, AND EMBALLS.

- [A.] 15,630. Bredel. Process for producing a new mass of rock quartz at a relatively low temperature.* July 31.

IX.—BUILDING MATERIALS, CLAYS, MORTARS AND CEMENTS.

- [A.] 15,747. Latham. Utilisation of old plaster casts and other hydrated sulphate of lime and apparatus therefor. Aug. 1.
- " 15,796. Jaspert, and Watson and Co., Ltd. Manufacture of artificial stone and tools thereof for working marble, granite, glass, &c. [Fr. Appl., May 16, 1905.]* Aug. 2.
- " 15,954. Morgan. Utilisation of slate waste. Aug. 1.
- " 16,426. Ford. Manufacture of artificial stone or sand-lime bricks. Aug. 12.
- [C.S.] 13,886 (1905). Colloseus. Process for the treatment of blast-furnace slag for production of materials similar to trass and the like. Aug. 16.

X.—METALLURGY.

- [A.] 15,675. Davies and Clarke. Welding or coating iron or steel with other metals or alloys. July 31.
- " 15,703. Beilby. Improving the tenacity of ductile metals and alloys. Aug. 1.
- " 15,809. Taylor and Mudford. Treatment of steel. Aug. 2.
- " 16,090. The Morgan Crucible Co., Ltd., and McCourt. Separation of the constituents of ores, &c., and apparatus therefor. Aug. 5.
- " 16,144. Nicholas. *See under I.*
- " 16,169. Tresidder. Manufacture of steel. Aug. 8.
- " 16,230. Thompson (Chas. W. Merrill). Treating precious metal-bearing materials. Aug. 9.
- " 16,232, 16,233, and 16,234. Wedge. Preparing iron oxide for treatment in furnaces.* Aug. 9.
- " 16,385. Hadfield. Manufacture of steel. [U.S. Appl., Aug. 13, 1904.]
- [C.S.] 20,842 (1904). Crosthwaite. Alloy employed in the manufacture of firebars. Aug. 10.
- " 21,088 (1904). Wilkins, Overend, Marsh and Hawthorne. Puddling and heating furnaces. Aug. 10.
- " 6388 (1905). Bergendal. Furnaces for calcining and burning briquettes of ore, and for similar purposes. Aug. 10.
- " 7131 (1905). Weiller and Weiller. Process for extracting copper from copper ore, more particularly from poor copper ore. Aug. 16.
- " 13,886 (1905). Colloseus. *See under IX.*

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

- [A.] 15,606. Gibbs. Manufacture of metal articles by electro-deposition. July 21.
- " 16,074. Loeb. Electric cells.* Aug. 5.
- " 16,132. Haswell, Cridge, and Bashforth. Electric furnaces. Aug. 8.
- [C.S.] 18,937 (1904). Hargreaves. Means and appliances for operating electrolytic cells. Aug. 16.

- [C.S.] 21,672 (1904). Lake (Sec. Anon. Le Carbone). Electric batteries. Aug. 10.
 „ 14,214 (1905). Kjellin. Electric furnaces. Aug. 10.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

- [A.] 15,961. Adecek. Wicks or substances used in the production of light in association with oleaginous or mineral materials. Aug. 4.
 „ 16,371. Gesner and Brandly. Process of, and apparatus for extracting oils *. Aug. 11.
 „ 16,406. Armstrong, Armstrong, and Armstrong. Manufacture of soap and detergent compounds. Aug. 12.
 [C.S.] 17,437 (1904). Heymann and others. *See under I.*

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

(A.)—PIGMENTS, PAINTS.

- [A.] 15,818. Le Maître. *See under I.*
 „ 15,912. Bindewald. Colours or varnishes. Aug. 3.
 [C.S.] 21,062 (1904). Bennett and Mastin. Manufacture of pigments. Aug. 10.
 „ 24,733 (1904). Bennett and Mastin. Manufacture of pigments. Aug. 16.
 „ 13,455 (1905). Alberti. Process for the preparation of lithophones. Aug. 16.

(B.)—RESINS, VARNISHES.

- [A.] 15,912. Bindewald. *See under XIII.*

XIV.—TANNING, LEATHER, GLUE, SIZE, Etc.

- „ 16,251. Fell. Treatment or finishing of hides or skins. Aug. 10.
 „ 16,312. Bivière, Verroul, and Bouvier. Tanning of hides or skins. Aug. 10.
 „ 16,432. Luther. Manufacture of glue. Aug. 12.
 [C.S.] 2477 (1905). Hutchinson. Hide working machines. Aug. 10.

XV.—MANURES, Etc.

- [C.S.] 23,045 (1904). Bollé (C. Schmidt und Co.). Process of and apparatus for manufacturing manure from offal and the like. Aug. 10.

XVI.—SUGAR, STARCH, GUM, Etc.

- [A.] 16,269. Stewart and Wishart. Evaporators for sugar and the like. Aug. 10.
 [C.S.] 1651 (1905). Littmann and Littmann. Compressed starch. Aug. 10.

XVII.—BREWING, WINES, SPIRITS, Etc.

- [A.] 16,071. Wittemann. Process of fermentation in relation to brewing beer and other beverages. [Ger. Appl., Aug. 6, 1904.]* Aug. 5.
 [C.S.] 18,488 (1904). Lennox. *See under I.*

XVIII.—FOODS; SANITATION, WATER PURIFICATION; & DISINFECTANTS.

(A.)—FOODS.

- [A.] 15,667. Weil. Manufacture of baking powder. July 31.

(B.)—SANITATION; WATER PURIFICATION.

- [A.] 15,987. Cameron and Commin. Process for treatment of sewage and other such waste products and means for carrying same into effect. Aug. 4.
 „ 16,121. Horsfall. Washing and cleansing fluid for domestic purposes. Aug. 8.
 „ 16,144. Nicholas. *See under I.*
 „ 16,177. Clark (American Water Purifying Co.). Method and apparatus for purifying water. Aug. 8.
 [C.S.] 18,488 (1904). Lennox. *See under I.*
 „ 19,444 (1904). Adams. Filter beds for sewage and other purposes. Aug. 10.
 „ 21,558 (1904). Freyssing and Roche. Sterilising and purifying water and other liquids. Aug. 10.
 „ 23,045 (1904). Bollé (Schmidt und Co.). *See under XV.*
 „ 8366 (1905). Pulinx and Pulinx. Decanting apparatus for purifying water. Aug. 16.

XIX.—PAPER, PASTEBOARD, Etc.

- [C.S.] 7140 (1905). Hölken. Improving paper by steam. Aug. 10.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

- [A.] 16,151. Heinrici. Process for preparing a stable solution of hydrogen peroxide.* Aug. 8.
 „ 16,348. Ewan and Young. Manufacture of guanine salts. Aug. 11.
 [C.S.] 16,996 (1904). Boehm (Merck). Manufacture of new oxycyanamido derivatives of pyrimidine. Aug. 10.
 „ 9656 (1905). Gries. Preparation of *m*-iodoxyquinolin-*ana*-sulphonic acid readily soluble in the stomach, and internal disinfectants containing the same. Aug. 10.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

- [A.] 16,227. Imray. *See under IV.*
 [C.S.] 21,208 (1904). Brasseur. Photographic or transfer paper. Aug. 10.

XXII.—EXPLOSIVES, MATCHES, Etc.

- [A.] 16,002. Upton. Explosive compounds. Aug. 10.
 „ 16,290. Kings Norton Metal Co., Bayliss and Hensses for lyddite shells and other explosive projectiles. Aug. 10.
 „ 16,320. Nathan, Thomson and Thomson. Manufacture of nitrocellulose. Aug. 10.
 [C.S.] 27,706 (1904). Mikolajizak. Manufacture of nitroglycerine. Aug. 16.
 „ 8746 (1905). Thomas. Manufacture and production of chlorated explosives. Aug. 16.

JOURNAL OF THE Society of Chemical Industry.

A RECORD

FOR ALL INTERESTED IN CHEMICAL AND ALLIED MANUFACTURES.

ISSUED TWICE A MONTH.

No. 17.—Vol. XXIV.

SEPTEMBER 15, 1905.

No. 17.—Vol. XXIV.

Subscription of Members 25 - per annum ;
Entrance Fee 21 - ;
Election by the Council.

Price to Non-Members 36 - per annum ;
To Members 25 - per Set of extra or back numbers.
Single copies (Members and Subscribers only)
1882—1901, 2 6 each ; 1902 *et seq.*, 1 9 each.

he Society of Chemical Industry.

Past Presidents :

Sir Henry E. Roscoe, B.A., D.C.L., LL.D., Ph.D., F.R.S.	1881—1882.
Sir Frederick A. Abel, Bart., K.C.B., G.C.V.O., D.C.L., D.Sc., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
V. H. Perkin, LL.D., Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Sir James Dewar, M.A., LL.D., F.R.S.	1887—1888.
Ludwig Mond, Ph.D., F.R.S.	1888—1889.
Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
E. Rider Cook	1890—1891.
Emerson Reynolds, M.D., F.R.S.	1891—1892.
Sir John Evans, K.C.B., D.C.L., LL.D., Sc.D., F.R.S.	1892—1893.
E. C. C. Stanford	1893—1894.
E. Thorpe, C.B., LL.D., Sc.D., Ph.D., F.R.S.	1894—1895.
Thomas Tyrer	1895—1896.
Edward Schunck, Ph.D., F.R.S.	1896—1897.
Frank Clowes, D.Sc.	1897—1898.
George Bellby	1898—1899.
F. Chandler, D.Sc., M.D., Ph.D., LL.D. Sir Jos. W. Swan, D.Sc., M.A., F.R.S.	1899—1900.
Frank Levinstein	1900—1901.
Sir W. Ramsay, K.C.B., D.Sc., LL.D., F.R.S. Wm. H. Nichols, M.S., LL.D., D.Sc.	1901—1903. 1903—1904.
† Deceased.	1904—1905.

LIST OF COUNCIL, 1905—1906.

President : Dr. Edw. Divers, F.R.S.

Vice-Presidents :

Baelkand.	Dr. J. Lewkowitch.
ter Bell.	N. H. Martin.
rgil Coblenz.	Max Muspratt.
W. R. E. Hodgkinson.	Dr. Wm. H. Nichols.
Howard.	T. J. Parker.
Levinstein.	Sir Wm. Ramsay, K.C.B., F.R.S.

Ordinary Members of Council :

T. Dunn.	Dr. K. E. Markel.
Guttmann.	B. E. R. Newlands.
mingway.	Prof. W. J. Pope, F.R.S.
V. R. Lang.	Sir Boverton Redwood.
Ling.	Walter F. Reid.
McArthur.	Dr. W. S. Squire.

Sectional Chairmen and Secretaries :

Official Notices.

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

SIXTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY, ROME, 1906.

The Sixth International Congress of Applied Chemistry will be held in Rome in April, 1906, during Easter week. All communications should be addressed to the President, Prof. E. Paternò, Via Panisperna, 89 Rome.

Changes of Address.

When notifying new addresses, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is also to be avoided as tending to create confusion. When sending subscriptions, the use of the form attached to the application helps in the verification of addresses, on which the safe delivery of the Journal depends.

- Dobbs, Roger, 1 o Dunnow; 4, Marlborough Terrace, Scotland Gate, Morpeth, Northumberland.
 Fraser, Hans A., 1 o c/o F. J. Falding; 52, Broadway, New York City, U.S.A.
 MacMahon, F. W., 1 o Sydenham; 31, Marler Road, Forest Hill, S.E.
 Marriott, F. Grant, 1 o Toronto; Goethestrasse, 22, Freiburg, 2 B., Germany.
 Mason, Dr. Edward D., 1 o Manchester; 22, George Road, Edgbaston, Birmingham.
 Parrish, S., 1 o Arthington; 80, Grange Avenue, Leeds.
 Patterson, W. Hamilton; Journals (temporarily) to The Sycamores, Ballasalla, Isle of Man.
 Saunders, Lewis E.; Journals to c/o Norton Emery Wheel Co., Niagara Falls, N.Y., U.S.A.
 Sawin, Luther R., 1 o Katonah; Mt. Kisco Laboratory, Mount Kisco, N.Y., U.S.A.
 Strayer, D. W., 1 o Bayonne; American Nickel Works, Cor. State and 10th Sts., Camden, N.J., U.S.A.
 Szegő, A. S., 1 o Warrington; Arvaer Comitát, Szlanicza, Hungary.

THE FORMATION OF SULPHURIC ESTERS THE NITRATION OF CELLULOSE AND THE INFLUENCE ON STABILITY.

BY C. NAPIER HAKE AND R. LEWIS.

(This J., 1905, 374—381.)

AUTHORS' REPLY TO DISCUSSION.

The discussion which followed the reading of our paper on April 3rd, 1905, appears to us to embody strong practical evidence in confirmation of our results. We do not think that an extended reply is called for, but would like to be allowed a few brief remarks on some of the points raised by those who took part in the discussion.

Dr. Dupré, in a written communication read by the Chairman, says:—

1. "The authors favour, I think, the production of a subsequent retention of an undue proportion of sulphuric esters," &c.

The object of our research was not to produce, in the first instance, a stable nitro cotton, but to determine the presence of sulphur compounds and their influence on stability.

2. "In spite of this the highest proportion of sulphuric acid, presumably in the form of sulphuric esters, was 0.79 per cent."

The conditions most favourable to the formation of sulphuric esters may not have been observed by the question requires further research.

Dr. Dupré also remarked that:—

3. "In the first place, the guncotton involved was of very recent manufacture, and, in the second place, the amount of free sulphuric acid found in one 8 oz. disc (nearly 0.5 per cent.) would imply the production of 1.5 per cent. of sulphuric acid from esters present in a guncotton, which had passed, as far as the evidence went, all the then accepted stability tests."

The explosion occurred on August 12th, and, according to the evidence, "on July 28th, or exactly a fortnight before the explosion, a quantity of impure guncotton narrowly escaped introduction into the magazine."

Mr. Prentice† stated that he believed at the time that a poacher full of cotton, which had accidentally omitted to be subjected to the usual tests, had, by mistake, been put before the purification was complete."

We do not for a moment doubt that if the impure cotton had been submitted to "the then accepted stability tests" it would not have been passed. Dr. Dupré appears to have overlooked the opinion expressed by Captain Majendie on the "arrangements for sampling," &c., which we quoted in our paper.

The deduction drawn by Dr. Dupré as to the quantity of sulphuric esters which would have been present in the discs is in accordance with our maximum results (per cent. H_2SO_4) and those of Messrs. Cross and Barrow. In regard to the rate of decomposition of the sulphur ester, we clearly stated in our paper that, so long as moisture is present in the nitro cotton, decomposition takes place slowly, even at a raised temperature, but as soon as the moisture is driven off the rate of decomposition increases rapidly: free sulphuric acid is formed which reacts on the nitro cotton, liberating nitro-organic compounds which again continue the chain action. This would explain the uneven distribution of the free sulphuric acid in the discs. The method adopted at the time of the investigation was, we gather from the evidence, simply washing the guncotton with water. This would,

* Report on the explosion of guncotton at Stowmarket, August 11th, by Vivian Dering Majendie, Captain Royal Artillery, page 24.

† Ditto, page 25.

course, not remove a sulphuric ester. This view is confirmed by the evidence at the inquiry. Dr. Duprétes with regard to the unfinished cotton which had passed the beaters, in other words, that had not yet been pulped or washed, that, as of course was to be anticipated, it contained some free acid, but the quantity was very small (0.007 per cent.). Dr. Odling found in cotton similarly treated 0.025 per cent. sulphuric acid. Messrs. Cross and Bevan have referred us to their paper published in the Berlin Berichte. We must admit that, though a careful search was made at the time of writing our paper, we overlooked their work and were thereby ignorant of its existence. For the omission we express our regret.

Mr. H. de Mosenenthal calls attention to an omission in our part in stating experiments to which he attaches considerable importance. His statement of the results of his experiments, to which he calls attention, is inaccurate and, therefore, misleading, as the following extracts from official publications will show. "A very exhaustive chemical examination of these consignments was made with a view of coming to a final decision as to their disposal. The results obtained led me to the conclusion that the explosive which, on arrival, reacted by the heat test in six minutes had considerably improved, showing reactions in from 10 to 25 minutes, that the explosive which originally reacted under five minutes had not improved. The contention of the experts of the material, viz., that it would improve on aging, was, therefore, to some extent substantiated." "*Blasting Gelatine*."—"The 35 samples referred to, rejected in the above table, represent consignments which were imported in 1896, and which have since that time been under observation. The general conclusion arrived at from repeated experiments is that blasting gelatine, possessing an abnormally low heat test does not improve (in this country at least) by keeping."

Sydney Section.

Meeting held at Sydney, on Wednesday, July 12th, 1905.

PROF. LIVERSIDGE, F.R.S., IN THE CHAIR.

CAUSE OF EXUDATION OF NITROGLYCERIN FROM "GELATIN COMPOUNDS."

BY C. NAPIER HAKE.

The rejection of explosives on account of exudation, in the area of my jurisdiction in Australia, has, within a few years, been a comparatively rare occurrence. One peculiar brand of imported explosives, however, appeared to be specially liable to exudation. The explosive was otherwise of excellent quality in regard to chemical and physical properties. On carefully examining the cartridges with a magnifier, the pearls of nitroglycerin were observed on the outside of the wrappers: the wrappers were also found to be of an absorbent nature. On removing one of these from the cartridge, and placing it under a falling weight, it was found to be so. On analysis the wrapper was found to contain 20 per cent. of nitroglycerin. The following experiments were made with the object of ascertaining that the exudation was due to the quality of the paper. For each experiment four cartridges were selected from the brands of "gelatin compounds." The wrappers on the cartridges were marked "A," "B," "C," and the explosives "x," "y," "z" respectively. "D" represented the wrappers which were submitted to me by the agents of the "Ax" brand, and approved of in lieu of wrappers of the "quality."

The "x" cartridges were exuding, and explosives "x" were re-folded in new wrappers of the same quality as the

originals ("A"). The other cartridges were taken in their original form as no exudation was visible.

Four cartridges of each series were then placed in separate boxes, specially made for the purposes of the experiment, and subjected to a direct pressure of 5 lb. for 72 hours. The temperature of the air during the experiment varied between 66 and 68° F. The cartridges were examined every 24 hours.

TABLE I.

Duration of experiment, in hours.	"x" explosive folded in "A" wrapper.	"y" explosive folded in "B" wrapper.	"z" explosive folded in "C" wrapper.
24	Wrapper stained outside with nitroglycerin.	no exudation	no exudation
48	Pearls of nitroglycerin on outside of wrapper.	no exudation	no exudation
72	In and outside of wrapper covered with nitroglycerin.	no exudation	no exudation

The explosive and wrappers were then interchanged, "x" explosive being folded in "B," "C" and "D" wrappers, and "y" and "z" explosive in "A" wrappers, and the same conditions applied as the former experiment. The following results were obtained:—

TABLE II.

Duration of experiment, in hours.	"x" explosive folded in "B," "C," "D" wrappers.	"y," "z" explosive folded in "A" wrappers.
24	no exudation	Wrappers stained, slight exudation extending to outside of wrappers.
48	no exudation	exudation increased.
72	no exudation	in and outside of wrappers covered with nitroglycerin.

The above experiments were repeated four times under similar conditions, and the first result confirmed in each case.

Wrappers belonging to series "A," "B," "C," and "D" respectively were then examined, with the results tabulated below:—

	"A."	"B."	"C."	"D."
Ash	1.22 per cent.	0.47%	0.70%	0.50%
Immersed in milk of lime for 4 hours.	yellow, brown tint	practically no reaction.		
Immersed in an aqueous solution of ferric chloride and potassium ferricyanide for five minutes.	dark blue tint	practically no reaction.		

A pine-wood paper gave the same tint of blue as in "A," after immersion in a solution of ferric chloride and ferricyanide of a similar strength and for the same time (five minutes).

The above reactions indicate that "A" wrappers represent a ligno-cellulose paper, or a paper containing a large proportion of ligno-cellulose.

Lotter,* in a paper on "Parchment Paper for Osmoses and other Purposes," says: "Parchment paper is prepared by the action of sulphuric acid upon unsized paper, preferably that made from cotton rags and free from such admixtures as wood meal (ground wood), which would become charred by the acid, forming small holes in the finished product." This interesting observation appears to explain the origin of the porosity of "A" wrappers, to which property the cause of exudation from the explosive folded in them must be assigned.

This view receives further confirmation from the fact

* This J., 1895, p. 58.

that since the above experiments were completed, over 200,000 lb. of explosive folded in "D" wrappers have been imported, and only in one instance has exudation been observed in a few cartridges, and at the end folds only; and this, I concluded, after careful examination, was due to the fresh explosive being too tightly folded in the wrappers.

That the freedom from exudation of nitroglycerin of "Dx" brand was not due to any manufacturing change in the explosive was shown by folding the explosive in "A" wrappers and subjecting the cartridges to pressure under conditions above recorded; exudation was induced at the same rate and to the same extent as in "Ax" tabulated above (Table I.).

DISCUSSION.

Mr. T. STEEL suggested that, as the unsuitability of the wrapping papers referred to was said to be due to their porosity, a microscopical examination might have shown the pores. He thought the chemical tests applied were hardly conclusive that pine cellulose was the cause of the defect.

Mr. W. A. DIXON thought that many of the accidental explosives of nitroglycerin were probably a result of exuding drops, as described in the paper. It seemed as if manufacturers often did not pay sufficient attention to the details of their work.

The CHAIRMAN asked whether, if porosity was caused by the charring action of sulphuric acid on cellulose

particles, it would not be possible to detect black spots where this had occurred. Might the porosity not be due to capillary action in the cellular structure of the paper? With Mr. Steel, he regretted the absence of microscopical examination.

Mr. HAKE wrote, in reply, that perhaps, in his note, failed to state clearly that the wrappers used for folding nitroglycerin compounds were made of parchmentised paper. In the process of parchmentising, the paper was attacked, the fibres swelled and gelatinised, and on treatment with water hydrate of cellulose was formed and deposited in the pores of the paper, rendering it impermeable to the flow of liquids through it. In the absence of original samples of the paper (before parchmentising) for the purpose of comparison the microscopic examination was not sufficiently conclusive. The wrappers, marked "A," showed considerably more erosion than "B," "C," and "D" wrappers. The examination was not referred to in the note as practical experiments, and the chemical tests appeared to him to fully prove his point.

The chemical tests, to which exception was taken, were well recognised tests. The reaction with ferric chloride ferriyanide was highly characteristic of lignocellulose.

No explosive which exuded badly was allowed to go into consumption; and the cause of exudation was formed the subject of his note was evidently of very occurrence, as it was the only instance which had come under his notice during the last fifteen years.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—8d. each, to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London W.

United States.—1s. each, to the Secretary of the Society.

French.—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs Bourgeois, Paris (3^e).

I.—PLANT, APPARATUS & MACHINERY.

ENGLISH PATENTS.

Drying Apparatus; Imps. in —. A. Huillard, Suresnes. Eng. Pat. 18,978, Sept. 2, 1904.

The apparatus, which is specially suitable for drying pasty and liquid bodies, consists of an endless band of metallic netting, the individual strands of which are wire spirals. This endless band travels over rollers through a series of drying chambers, a current of heated air being

drawn through the chambers in the opposite direction. The band passes first through a vessel containing the material to be dried, and becomes coated with it; it then passing through the drying chambers it enters the depositing chamber, and passes between rotating rollers, whereby it is repeatedly bent back upon itself and the dried substance is detached. The band then passes over a rotating frame, which imparts a shaking motion to it and causes it to strike against a grating where any material still remaining on the band is detached. The band then leaves the depositing chamber and passes through the vessel containing the material to be dried, to take up a fresh supply.—W. H. C.

Drying Moist Material: Apparatus — E. N. Trump, Syracuse, N.Y. U.S. Pat. 790,102, May 16, 1905.

CLAIM is made for improvements in apparatus described in U.S. Pat. 748,893 of 1904 (this J., 1904, 111).

The apparatus is similar in construction to that described in U.S. Pat. 788,741 of 1905 (see above). The material is fed into the apparatus in a similar manner, but the upper part of the column contains a conical collecting or separating chamber for the dried material, with a delivery pipe passing from the bottom of the cone through the side of the upright column. The dust chamber and supplementary separator are dispensed with and the drying agent is conveyed through a valved pipe, provided with inlet and outlet connections for introducing fresh, and withdrawing exhausted drying agent, back to the heater and blower.—W. H. C.

Evaporating Apparatus: Multiple Effect — S. M. Lillie, Philadelphia, Pa. U.S. Pat. 789,159, May 9, 1905.

A CIRCULATING pump is bolted directly on to the under side of the tank or evaporator so that it is supported entirely by the latter. The pump is of the paddle-wheel type, the wheel rotating in a casing and being carried by a shaft passing through stuffing-boxes and journals attached to the casing. The intake of the pump opens directly into the evaporator, and a deflecting plate is arranged within the latter over the intake opening, to cause the fluid to take a circuitous passage to the pump. The pumps are so attached, that they can be removed without interfering with the internal construction of the evaporators, and, when two or more evaporators work together, they are arranged in line so that the pumps may all be driven from one shaft.—W. H. C.

II.—FUEL, GAS, AND LIGHT.

Internal Combustion Engines, Dugald Clerk, Cantor Lectures. J. Soc. Arts, 1905, 53, 870—880, 888—899, 906—913, 923—932.

LECTURE 1 treats of the fundamental principles of internal combustion engines, with some remarks on the thermodynamics of air engines; then follow theory of compression; efficiencies without heat or other losses; gaseous explosions and measurement of temperature in such by various methods, coal gas, petrol, alcohol, and producer gas explosions. LECTURE 2 deals with indicator diagrams and power tests; diagrams are given for engines using various gases. Irregularities in diagrams, pre-ignitions, exhaust-explosions, and missed ignitions are also discussed. In LECTURE 3 various types of gas engines are described and discussed. LECTURE 4 touches briefly on petrol engines, and then proceeds to discuss suction gas producers, blast-furnace gas and producer gas and their utilisation for various purposes, air supercompression and exhaust supercompression, concluding with a short description of marine gas and oil engines, and a few suggestions as to the lines along which advance in gas engines will probably be made; under this last heading it is pointed out that lighter producers are necessary, and that they should be capable of utilising any fuel, bituminous or non-bituminous.—T. F. B.

Coal: Examination of — O. Pfeiffer, XXIII., page 943.

ENGLISH PATENTS.

Coke Ovens and Gas Generating Plant: Gas Delivery and Purifying Apparatus for — H. Koppers, Essen-Ruhr, Germany. Eng. Pat. 16,008, July 19, 1904.

THE expansion pipe *a*, which is attached to the coke oven or gas retort mouthpiece has an expansion *b* into which the end *c* of the arch pipe or bend *e* fits by a ribbed "spherical joint." This allows any displacement, caused by the expansion of the pipe *a* by heat, to take place without injuring the joint. The other end *k* of the arch pipe *e* dips into the cup *h* which is kept full of water to form a hydraulic seal. The extension *i* projecting a short distance

into the pipe *l*, which rests on the top of the gas collecting main *f* by the flange *g*, serves to prevent any tar or pit from falling into the seal cup *h*. When it is necessary

remove the pipe *e*, the cup *m*, which has normally the position indicated by the dotted lines, and serves to collect any tar or pitch dropping from *k*, is raised by the rod *n*, passing through the guides *o*, into the position shown by the continuous line. The end of the pipe *l* being sealed by the cup *m*, *e* may be safely removed and any pitch that has collected in *m* can be cleaned out.—W. H. C.

Gas: Manufacture of Producer — applicable to Pressure and Suction Plants. H. E. Smith, London. Eng. Pat. 16,069, July 20, 1904.

By means of an expansion chamber connected to the exhaust pipe of a gas engine and a suitable arrangement of valves, any desired proportion of the exhaust gas mixed with air and passed beneath the grate of the generator. The carbon dioxide in the exhaust gas combines with the carbon of the fuel to form carbon monoxide and thus effects a saving of fuel. It also enables a portion of the steam, which is passed into the generator for the purpose of cooling it and rendering clinkering possible to be dispensed with.—W. H. C.

UNITED STATES PATENT.

Gas: Process of Producing — C. Ellis, Assistant to the Eldred Process Co., New York. U.S. Pat. 791,961, July 25, 1905.

THE process for the production of combustible gas having a high content of carbon monoxide, and a low content of carbon dioxide, consists in introducing into the producing mass of fuel an air-blast containing an endothermic constituent only carbon dioxide, approximately equivalent in amount to that which would be produced by the passage through the fuel of an air-blast containing no constituent which has an endothermic reaction, and thereby artificially creating within the fuel mass the carbon dioxide partial pressure, whereby a relatively large amount of fuel is converted into combustible gas.—W. C. H.

FRENCH PATENTS.

Coal: Method of Recovering Solid Material in the Residual Waters from the Washing of — R. Zörner, Frankfurt. 352,499, March 15, 1905.

THE residual water is conducted into a tank through a pipe opening into a space between two strainers, which

$$C_6H_4 \leftarrow \begin{array}{c} \text{---} C; C(R), C \text{---} \\ N(HCl); C(CH_3), C(CH_3), NH \end{array} C_6H_5$$

ENGLISH PATENTS.

Brown monoazo dyestuffs, developed by chroming, are produced by combining an *o*-diazophenol derivative with a derivative of 1:2:4- or 1:2:6:4-diaminobenzene of the general formula $R.NH.C_6H_2N(X)(NH_2)_2$, where R is a radical of the benzene or naphthalene series and X is hydrogen, SO_3H or $COOH$, obtained by condensation of a base of the benzene or naphthalene series or its sulphonic or carboxylic acids with 1:2:4-chlorodinitrobenzene or dinitrochlorobenzene sulphonic or carboxylic acid ($NO_2 : NO_2 : Cl : SO_3H$ or $COOH = 1 : 3 : 4 : 5$ or $2 : 6 : 1 : 4$) and subsequent reduction. The combination of the diazo-compounds with the triaminobenzene derivatives occurs, in part, even in mineral acid solution, but better in acetic acid or sodium carbonate solution. For example, the diazo-derivative obtained in the usual manner from 20 kilos. of picramic acid is mixed with a concentrated solution of 30 kilos. of sodium diaminodiphenylamine sulphonate (from 2,6-dinitro-1-chlorobenzene-4-sulphonic acid and aniline, and subsequent reduction). 30 kilos. of sodium acetate are added with stirring, the mixture is heated to 40° C. for one hour and 20 kilos. of sodium carbonate are slowly introduced. The product dyes wool from an acid bath in reddish-brown shades, which become deep brown when subsequently chromed, and are satisfactorily fast to fuling.—E. F.

NEW dyestuffs can be obtained by acting with a nitrating

agent, for example, nitric acid, on the dyestuffs obtained by acting with alkali hydroxide on compounds containing a benzanthrone group, for instance, on benzanthrone-quinoline. The products are insoluble in water, but soluble in alkali hydrosulphite solution to form a vat dyeing vegetable fibres in shades becoming green on exposure to air. The dyestuffs obtained by reduction of the new products are also claimed. The product obtained by treating with nitric acid the dyestuff obtained from benzanthrone-quinoline and alkali hydroxide, dyes vegetable fibres in shades which become yellowish-green on exposure to air. (See this J. 1905, 192, 726, 840, 841.)—F. F.

FRENCH PATENT.

Indophenol Sulphonic Acids; Production of —. K. Oelder. Fr. Pat. 352,200, March 8, 1905.

p-PHENYLENE-DIAMINE-SULPHONIC acid is oxidised with 1 mol. of a phenol in alkaline solution. For example, 47 parts of *p*-phenylenediamine-sulphonic acid and 27.2 parts of *m*-cresol are dissolved in 500 parts of water and 70 parts of sodium hydroxide solution of 35° B., cooled by ice and oxidised with a sodium hypochlorite solution equivalent to 8 parts of oxygen. The temperature may rise to 5° C. without serious alteration of the yield, which is almost quantitative. Products obtained with *o*-cresol, phenol and *α*-hydroxynaphthoic acid are also described. The products are very pure and are useful for the production of sulphide dye-stuffs.—E. F.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

Dyeing of Animal Fibres; Phenomena accompanying the —. P. Gelmo and W. Suida. Monatsh. f. Chem., 1905, 26, 855—878.

By treating purified wool with sulphuric acid, and afterwards washing with water, the affinity of the fibre for basic dyestuffs is considerably diminished, whilst its affinity for acid dyestuffs from a neutral bath is increased. If hot water be used for washing, the affinity of wool which has been previously treated with alcoholic sulphuric acid, is rather greater for basic dyestuffs than when cold water is used for the washing, whilst if the wool has been previously treated with aqueous sulphuric acid the reverse is the case. The affinity of wool for acid dyestuffs is considerably increased by washing with hot water, after treatment with either aqueous or alcoholic sulphuric acid. The behaviour of hydrochloric acid is quite analogous to that of sulphuric acid. Wool treated with acetic acid and then thoroughly washed, behaves exactly like the untreated fibre. Wool treated with tartaric acid, and subsequently washed, is dyed both by basic dyestuffs and by acid dyestuffs from a neutral bath. On boiling wool for one hour with an aqueous solution of aluminium sulphate, dilute sulphuric acid, or water, the authors found that it had undergone a very considerable loss of weight, due to partial hydrolysis, with formation of soluble amino-acids. Experiments were made on the action of cold N/10 solutions of sulphuric acid, hydrochloric acid and ammonia on wool and on silk, the liquids being afterwards titrated, using methyl orange as indicator. After five minutes the reaction had proceeded as far as in two hours. Wool absorbs 2 equivalents of mineral acid for each equivalent of ammonia, whereas silk absorbs 6.4 equivalents of ammonia to 1 of hydrochloric and 2 of sulphuric acid.

Purified wool was dyed with the pure free colour acids of Crystal Ponceau, Lithol Red, Fast Red R and Alizarin Yellow GGW. The intensity of the dyeings was not increased by adding mineral acids to the dye-bath, and the authors consider that any excess of mineral acid, above the amount needed to liberate the colour acid, which may be necessary in practice, is merely utilised to neutralise alkali of lime combined with the acid groups of the wool

and derived from alkali or hard water used in its purification. Wool was also treated with alcoholic potassium hydroxide solution, afterwards with slightly acidified water and then washed. After this treatment, the fibre which was yellowish in colour, showed increased affinity for Benzopurpurin 6B and Bordeaux Extra, showing that alkali had entered into combination with it. The action of alcoholic potassium hydroxide was quite analogous to that of aqueous potassium hydroxide used in previous investigations. Wool treated with alcoholic zinc chloride solution (0.1 per cent.) and washed, showed less affinity for basic dyestuffs and more for Azofuchsine G neutral solution, than when treated with aqueous zinc chloride solution. Wool was treated with alcoholic with aqueous sulphuric acid, then mordanted with a minimum, chromium or iron sulphate, and finally dyed with Alizarin Red S, or Anthracene Blue WG, soaped and washed. The initial treatment with sulphuric acid produced no effect in the case of chromium sulphate, the case of aluminium sulphate stronger dyeings, and with iron sulphate weaker dyeings were obtained than with the wool was not initially treated with dilute acid. Wool is mordanted with aluminium, chromium, or iron sulphate, without previous treatment with acid, it entirely loses its affinity for basic dyestuffs, whereas its affinity for Azofuchsine is increased. If it be treated, after mordanting with dilute ammonium carbonate solution, it acquires strong affinity for basic dyestuffs and almost loses its affinity for Azofuchsine. Wool mordanted with aluminium acetate almost loses its affinity both for basic and for acid dyestuffs from a neutral bath, whereas, when mordanted with aluminium tartrate, it acquires very considerable affinity for the latter. The behaviour of the various products of hydrolysis of wool towards mordants and dyestuffs was also studied. The aminobenzoic acid behaved very differently from the aminocarboxylic acids of the fatty series. The former cause the wool to take up Azofuchsine from an otherwise neutral bath, whereas the latter do not. The presence of peptone causes dyeings with basic dyestuffs to be very unstable to dilute solutions, and does not promote the dyeing of acid dyestuffs from a neutral bath, but does not hinder them from dyeing from a weakly acid bath. The soluble decomposition products obtained on boiling wool with water or dilute acids show all the reactions of a peptone and the production of dyeings not fast to soaping or rubbing for basic dyestuffs may thus be accounted for. Further experiments showed that dyeings of acid dyestuffs on wool previously treated with $\frac{1}{2}$ per cent. alcoholic sulphuric acid were faster to soaping than similar dyeings on untreated wool, wool previously treated with $\frac{1}{2}$ per cent. of aqueous sulphuric acid, or on wool from a sulphuric acid bath. The general conclusion of the authors is that the dyeing of wool is accompanied by a gradual hydrolytic disintegration of the wool-anhydride, soluble decomposition products being formed; that a decomposition is promoted by mineral acids, and is necessary for satisfactory dyeing; that the primary decomposition products resemble peptones and have a bad effect on the fastness of the dyeings in absence of mineral acids, and that these peptones are further dissociated, forming amino-acids.—E. F.

Dyeing Process; Theory of the —. W. Biltz. Naturges. Wiss. Göttingen, 1905, 46—63. Chem. Central, 1905, 2, 524—525.

THE first portion of the paper relates to dyeing tests which coloured colloidal inorganic substances and inorganic hydrogels were used as substitutes for organic dyestuffs and fibres respectively. The ordinary dyeing process may be represented by the equation—

where C^0 fibre is the concentration of the dyestuff in the dyed fibre and C dye-liquor the concentration of the dyestuff in the dye-bath, whilst the index n is greater than 1 and is frequently a whole number. Comparative experiments in which the organic dyestuff used was Benzopurpurin 6B and the inorganic substance used was Benzopurpurin 6B.

purin, and the inorganic colloids were Molybdenum and vanadium pentoxide, showed that there is no material difference between the dyeing properties of the mixed inorganic colloidal substances and organic dyes. In both cases the composition of the coloured matter after dyeing at a given temperature depends upon the conditions of the dyeing process, the concentration of the stuff and of the salts added to the dye-liquor. In further set of experiments the hydrogel of alumina was used in place of an organic fibre, and here again, it was found that the substitution of the inorganic colloid for an organic substance had no effect on the quantitative relations observed in the dyeing process. The author considers that the results of these experiments prove the correctness of the view that the dyeing of textile fibres with dyestuffs of the type of Benzopurpurin proceeds according to the "adsorption theory" (see this J. 1904, 4).

In the second portion of the paper, the results of some experiments with Immedial sulphur dyestuffs, made jointly with P. Behre, are described. By dialysis of solutions of the dyestuffs in alkali sulphides, clear colloidal solutions, free from alkali, were obtained, which were regulated by electrolytes in a similar manner to other colloidal solutions. The coagulating-power of the electrolytes on the dyestuff solutions, increased with the valency of the cation; nitrates were not so active as chlorides. Dyeing tests with solutions of Immedial dyestuffs, as used in practice, showed that the adsorption compounds of the dyestuffs with cotton have, as in the case of other colloids, a composition depending upon the concentration of the dyestuff in the solution. Similar results were obtained when the hydrogels of alumina, zirconium dioxide, ferric oxide and stannic oxide were substituted for the textile fibre.—A. S.

Sulphur [as Discharge]; Action of Alkali on —. — Pomeranz. Z. Farben- u. Textil-Ind. 1905, 4, 392-393.

The author considers that, in the reaction between sulphur and alkali hydroxides, the production of polysulphides and sulphates is preceded by that of monosulphides and polysulphites. Paranitraniline Red being dischargeable by hydrosulphite, the effect of sulphur and sodium hydroxide was tried. A thickened mixture of precipitated sulphur and sodium hydroxide (3NaHO and 2S) was printed on cotton tissue dyed with Paranitraniline Red and washed, when a fairly white discharge was obtained after severe soaping.—D. B.

ENGLISH PATENT.

Manufacture of Artificial —. — H. E. A. Vittenet, Rouen-Montplaisir, France. Eng. Pat. 1686, Jan. 27, 1905. Under Int. Conv., Dec. 8, 1904.

The invention consists in the use of pyroxylin dissolved in acetone, to which sulphurous acid is added. The thread so made is used to produce the threads. Or, the threads can be formed from an acetone-collodion in a moist or dry atmosphere containing sulphurous acid. The acetone can be recovered by passing the mixture of sulphurous acid and acetone vapour through a solution of caustic soda or sodium carbonate. (See this J. 1905, 3 and 799.)—F. S.

FRENCH PATENT.

Dyeing or Decorating Tissues, Paper, etc.; Process and Apparatus for —. — C. L. Burdick. Fr. Pat. 2,220, March 9, 1905.

The fabric is passed below, or above, sprays which work intermittently and are fed by various coloured liquids. The apparatus used, consists of rollers, between which the fabric is passed, and several groups of sprays, the operation of which is electrically or mechanically controlled; the object may be attained by electromagnets, controlling the supply of liquid and air to each spray; the magnets are intermittently supplied with electric current from a dynamo, the circuit being automatically made and broken

by the action of circular ridges on the ends of the pressure-rollers, these ridges being discontinuous and actuating small levers. The sprays are fixed on bars which have an automatic to and fro movement.—E. L.

VI.—COLOURING WOOD, PAPER, LEATHER, &c.

FRENCH PATENT.

Dyeing Skins; Continuous Machine for —. — R. Martinet and A. Dulac. Fr. Pat. 352,095, Feb. 7, 1905.

The skins are carried forward on an endless band, coated with india-rubber, which makes periodic movements in a forward direction. A frame, containing transverse partitions lined with india-rubber below, is raised at each forward movement of the endless band and lowered when it is at rest, then forming a series of separate compartments. Above each of these compartments is fixed a spray which describes a circular movement in a lateral plane in order to distribute the liquid. The supply of liquid from each spray is automatically stopped while the endless band is moving. Each skin traverses the various compartments in order, is sprayed in succession with a different liquid (mordant, dye-liquor, &c.) in each, and is finally rinsed with water in the last compartment.—E. F.

VII.—ACIDS, ALKALIS, AND SALTS, AND NON-METALLIC ELEMENTS.

Chamber Process; Latest Progress in the —, and its Influence on the Economy of Sulphuric Acid Manufacture. F. Lütty. Z. angew. Chem., 1905, 18, 1253-1264.

IMPROVEMENTS in details in the chamber process during the last 10 years have enormously increased the yield from chambers of a given capacity, and hence lessened the cost of production.

Kilns.—Mechanical burners for smalls (Herreshoff, Humboldt, O'Brien) have of late been extensively introduced. The cost of working these, however, does not

always compare favourably with that of hand-burners; indeed, hand-worked burners are cheaper than mechanical burners, if the cost of labour be below 4s. per man per shift. The chief advantage of the mechanical burners is that they minimise the number of men needed. *Glover Towers.*—Changes in detail here have effected considerable improvement in output. The nature and form of the filling-material is not of very much moment, provided that the interstices in the lower layers be sufficiently great (3—5 in.), so that the tower is not readily choked. A useful improvement in construction, introduced by Rohrmann and Niedenfuhr, is to have a second floor only a short distance above the bottom of the tower, so that the small quantity of material in the lower compartment can be readily renewed and changed without disturbing the main body of the filling. The Glover towers are now built of greater area and height than formerly, and are placed on a higher level relatively to the pyrites-kilns, so as to ensure a stronger draught from the kilns, and allow or more throttling behind the Gay-Lussac tower. *Gay-Lussac Towers.*—These are of larger size than formerly; for a daily out-turn of 50 tons of chamber acid there should be not less than 10,000 cb. ft. of space, divided among two or more towers, the last of which should be filled with coke. If a fan be used, the upper layers of coke may safely be of 2-m. size. *Chambers.*—By far the greater number of plants have rectangular chambers, long and nearly square in section, but tending to be higher and narrower than used to be the case. The chief innovations are Meyer's tangential chambers, and the introduction between or behind the chambers of Lunge's plate-towers. Over a very long period, one of these towers of 3000 cb. ft. gross capacity, placed at the end of a chamber-system of 285,000 cb. ft. capacity, gave a yield of 26.9 kilos. of chamber acid per cb. metre (say, 3 cb. ft. per lb. of sulphur burnt). *Fans.*—The use of fans has rendered the process much more controllable, and has, in consequence, greatly increased the yield, though for the most part the fan has had to be placed where it is of least service—either immediately before or after the Gay-Lussac tower. *Heat Removal.*—The increased intensity of reaction due to these improvements has necessitated the removal of some of the heat generated by the reaction; this has been accomplished largely by substituting water-spray for steam in the chambers, and by the introduction of plate-towers fed with a stream of cold acid.

By all these means, the output of the chambers has been increased from 3 or 4 to 6 or 7 kilos. of chamber acid per cb. metre of chamber-space (from 20—27 to 12—14 cb. ft. per lb. of sulphur burnt) per day, in systems working without plate-towers.

A recent patent of Niedenfuhr's (Ger. Pat. 140,825) marks a further important advance, by which the working of the pyrites burners is rendered independent of that of the rest of the process. The Glover tower is divided into two—a concentrating tower, in which the gases from the burners are cooled and freed from flue-dust by acid which has already been denitrated, and a denitrating tower, fed with acid from the Gay-Lussac tower, which is denitrated by these cooled gases. For complete denitration the nitrous vitriol must be diluted by chamber acid water (and steam, if need be) to a sp. gr. of 1.61; in a dilution to 1.65 ensures the issue of the acid with content of not more than 0.2 per cent. of nitric acid 1.33 sp. gr., which is completely removed in the concentrating tower, while the acid is brought up to sp. gr. 1.71—1.73. Between these two parts of the Glover tower is placed the fan, which satisfactorily resists the action of the cooled and very faintly nitrous gases with which it is thus brought into contact. The gains by this arrangement are—that the burners and the chambers are independent; the system may be severely throttled behind the Gay-Lussac tower, and yet the draught of the burners not be interfered with. Thus very concentrated burner-gas may be used, and the burners themselves may be worked with larger charges without increasing percentage of sulphur in the burnt ore. Again, different systems of burners may be used in combination to form one set of chambers, and variations in the number of burners simultaneously at work cause practically no disturbance in the process, whilst the negative pressure up to the fan prevents the possibility of loss of gas leakage. On the other hand, the uniform *plus* pressure in the chambers is favourable to the reaction, ensuring better utilisation of the chamber space, and lessens the liability of the occurrence of dead spaces, the gases being more thoroughly and intimately mixed. In each of the three installations worked on this system the output of acid was 9—11.5 kilos. of chamber acid per cb. metre (9—7 cb. ft. per lb. of sulphur burnt), and the nitre used was equivalent to 0.6—0.7 kilo. of nitric acid of sp. gr. 1.33 per 100 kilos. of chamber acid. As to pressure, it would seem that, for a given amount of gases, as the pressure is increased by throttling the exit from the Gay-Lussac tower, the process is transferred more and more towards the earlier part of the system, and finished in a smaller space; so that there is room for more gas in the unused portions of the chambers, and the yield is increased. The pressure need not be increased beyond the point at which the whole of the chamber space is just used for the complete reaction of the amount of gases entering, or the Gay-Lussac towers will not work properly (possibly through formation of nitrous peroxide.) Tables are given showing actual pressure in the three installations above mentioned, expressed in mm. of water-column. The details of the installations are as follow:—1. Two Glover towers, 12 ft. diameter by 32 ft. high; four chambers, 18 ft. wide, 33 ft. high, and respectively 113, 70, 33 and 53 ft. long. Total capacity, 162,000 cb. ft.; three Gay-Lussac towers, 6½ ft. by 4½ ft. high. 2. Two Glover towers, 11 ft. sq. by 32 ft. high; four chambers, 31 ft. wide, 28 ft. high, 124 and 65 ft. long; one tower between the chambers, 4740 cb. ft., and two plate-towers after the second chamber, 2700 cb. ft. each. Total capacity, 170,000 cb. ft.; two Gay-Lussac towers, 1½ ft. by 42 ft. high. 3. Two Glover towers, 10 ft. sq., 33 and 26 ft. high; two tangential chambers, 38 ft. diameter, 43 ft. high, followed by three plate-towers, 2550 cb. ft. each; total capacity, 108,000 cb. ft.; two Gay-Lussac towers, 10 ft. diameter, 40 and 50 ft. high.

1.3	7.0	5.8	5.4	4.5	0.9

The first table shows the effect of the resistance caused by the very narrow Gay-Lussac towers. In the second table, the first row of figures represents a state of things in which the whole space is utilised for the process; the second in which, by undue throttling, the reaction is concentrated in the earlier portions, and nitrous gases escape in considerable quantities from the Gay-Lussac towers. The very satisfactory results obtained from such widely different systems are only to be attributed to the position of the fan. Examination of the working of these systems has convinced Niedenführ that the theoretically best form of chamber is one resembling a tower, in which the progress of the gases is from top to bottom: with natural draught, this would have not been easily practicable, but with the pressure from the fan it presents no difficulty. The author gives details of a system working on Niedenführ's plan, designed for a daily production of 50 tons of vitriol (say 80 tons of chamber acid), and shown in plan and sections in the figures.

The burners F, for smalls, hand-worked, and built so that the pyrites can be run directly from stock to the hoppers, whilst the burnt ore is elevated to a store in which it can be run down directly into the railway trucks,—contain 44 divisions of 200 sq. ft. area each in three stages. The gases collect in the flue K, and then reverse (twice downward and once upward) the dust-burners J, before reaching the concentrating (Glover) or CG. Thence they go by the pipe R₁, 28 in. diam., to the fan, which is below the chambers, returning by R₂ (28 in.) to the denitrating Glover tower DG. From there they go by R₃ (28 in.) to the top of the first chamber, which they enter by two 24 in. branches. They leave each chamber about 3 ft. from the bottom, and enter next at the top; the chambers are 47 ft. long, 20 ft. wide, 16 ft. high, and the connecting pipes 26 in. diam. The pipe R₄ (27 in.) leads from the last chamber to the plate tower LT, 13 ft. sq. and 28 ft. high, whence by R₅ (26 in.) the gases go to the cooler GE, and then by 26 in. pipes through the Gay-Lussac towers and a throttle-valve to the atmosphere. The capital outlay for this installation will be:—Land, 1800 sq. m. at 20 M. (2150 sq. yds. at 9d.) 36,000 M.; buildings, 78,000; machinery, 500; pyrites burners and appurtenances, 72,500; chambers and towers 116,000; total 320,000 M. (416,000). The installation will need 16 h.p., and 24 men (16 for the burners, 4 for transport of pyrites and burnt ore, 4 for chambers and machinery). Repairs will cost 12,000 M. annually. Calculating all these, with interest and depreciation as above, and the cost of pyrites, on the basis of chamber acid containing 100 kilos. of monohydrate, the costs are:—pyrites 1.28 M.; nitre 0.21; power 0.0307; repairs 0.144; interest and depreciation 0.072; total 1.9386, say, 1.94 M., a saving of 17 per cent. on the figure quoted in 1902 (2.33 M., this J., 1902, p. 9d.). Using this new figure, the cost of 93 per cent. acid produced by Kessler's apparatus, is estimated at 9 M. instead of 2.56 M., for 100 kilos. The author finally states that if water-spray be adopted and electric power supplied, a steam generator is superfluous.—J. T. D.

Chamber Process; Theory of the — F. Raschig, Z. angew. Chem. 1905, 18, 1281—1323.

1. NITRIC oxide mixed with excess of oxygen forms at once the trioxide, and this slowly oxidises further to peroxide; the relative speeds of the two reactions are roughly as 100:1. Both reactions are of course retarded when the oxygen is diluted by an indifferent gas; and in a mixture containing the same proportion of oxygen as exists in the chambers, the oxidation to trioxide is complete in about three seconds, whilst the oxidation to peroxide requires about five minutes. From this fact alone it seems necessary that the substance which reacts in the chamber on sulphur dioxide should be nitrogen trioxide—peroxide could not be reduced and reformed with the necessary frequency. 2. The same conclusion is reached, when the behaviour of nitrogen trioxide and peroxide towards sulphur dioxide in presence of water is examined: the former at once reacts, but the latter, as such, does not react at all—it dissolves in the water to form a mixture of nitric and nitrous acids, only the latter of which reacts. Thus a molecule of nitrogen trioxide converts twice as much sulphur dioxide into sulphuric acid as does a molecule of peroxide. 3. Nitrogen trioxide, or nitrous gases approaching it in constitution, dissolve readily in strong sulphuric acid, and from the analysis of the solution the composition of the gas can be accurately deduced; but when these gases are absorbed by water or by sodium hydroxide, a portion always breaks up into nitric oxide and nitrogen peroxide, the former escaping, and the latter yielding nitrite and nitrate in equimolecular proportions—the analytical error resulting from this amounts with pure trioxide to 17–20 per cent., but in presence of diluting gases may be as low as 5 per cent. On the other hand, gases near to nitrogen peroxide in composition dissolve readily and completely in sodium hydroxide, forming nitrate and nitrite, and their composition can be accurately determined by analysis of the solution; but in strong sulphuric acid they dissolve with difficulty, and undergo partial decomposition and loss of both oxygen and nitrogen. 4. The product formed when nitrogen trioxide dissolves in sulphuric acid (chamber crystals) is not nitrosylsulphuric acid NO.O.SO₃H, but nitrosulphonic acid O₂N.SO₃H. By reducing agents it is converted into "nitrosulphonic acid" (ON(OH)SO₃H). This substance dissolves in strong sulphuric acid with a bright blue colour, in weaker acid with a faint red colour, which becomes bright violet on addition of a few drops of copper sulphate solution. It is very unstable, readily breaking up into sulphuric acid and nitric oxide. The determination of nitrogen in the nitrometer depends upon the formation and decomposition of this substance. Nitrosulphonic acid forms with copper and iron salt-like compounds, much more stable than the acid itself. These salts are not decomposed in the nitrometer, which, therefore, cannot be used to determine nitrogen in substances containing copper and iron. 5. Nitrosulphonic acid is formed when nitrosulphonic acid and sulphurous acid react; not, however, directly, but by the decomposition

of the nitro-acid into sulphuric acid and nitrous acid, the latter of which then reacts on the sulphur dioxide, forming nitrosulphuric acid, which with a second molecule of nitrous acid yields nitrosulphuric acid and nitric oxide. These are the reactions in the Glover tower: the nitrosulphuric acid then breaking up into sulphuric acid and nitric oxide, and the whole of the nitric oxide then oxidising again to nitrogen trioxide, to repeat the cycle of operations. 6. The reactions in the chamber are the same as those in the Glover tower (except, of course, the breaking up of the nitrosulphuric acid); the whole cycle is represented by the equations:—

1. $\text{ON.OH} + \text{SO}_2 = \text{ON.SO}_2.\text{OH}$
2. $\text{ON.OH} + \text{ON.SO}_2.\text{OH} = \text{NO} + \text{ON(OH)SO}_2.\text{OH}$
3. $\text{ON(OH)SO}_2.\text{OH} = \text{NO} + \text{H}_2\text{SO}_4$
4. $2\text{NO} + \text{O} + \text{H}_2\text{O} = 2\text{ON.OH}$

In aqueous solution nitrosulphuric acid tends to decompose even in presence of nitrous acid, yielding sulphuric acid and nitroxyl (or nitrogen monoxide). But when for water is substituted sulphuric acid, this tendency is lessened and the tendency towards reaction (2) increased as the strength of the sulphuric acid is increased; and in presence of chamber acid the reaction (2) proceeds with even greater speed than (1), so that the moment nitrosulphuric acid is formed it is all converted into nitrosulphuric acid. Ordinarily the whole of the nitrosulphuric acid is again decomposed, but in certain states of the chambers, when their working is disturbed, its presence in small quantity in the chamber acid can be demonstrated. 7. The reaction in the chamber-process is accelerated by rise of temperature; and in the Glover tower both the intensity of the reaction (yield per cb. ft.) and the strength of the acid are higher than in the chambers. It is however, necessary to cool the chambers, because the reactions are reversible, and the final product must, therefore, be removed; were the temperature allowed to rise the opposing tendency of the gaseous sulphuric acid to decompose would soon more than counterbalance the increased speed of reaction. The mixture in the chambers is also very different from that in the Glover tower; hence, although much has been done of late years, especially by great increase in the amount of nitrous compounds present, to increase the intensity of reaction in the chambers, they are still, and must be, in this respect far behind the Glover tower. 8. The reaction (3) occurs the more readily as the temperature is higher; if the chamber-working be disturbed, so that not the whole of the sulphur dioxide is converted into sulphuric acid in the chambers, and the reactions (1) and (2) occur in the cold Gay-Lussac tower, reaction (3) may not occur at all. In this case the nitrous vitriol runs away "purple," and some loss of nitrogen compounds occurs through escape of nitric oxide between the Gay-Lussac and the Glover, or even in the Gay-Lussac tower itself. This state of things, however, is by all good makers considered preferable to that in which all the sulphur dioxide is oxidised before the whole of the chamber space is traversed, and when, consequently, there is time for nitrogen peroxide to be formed at the end of the chambers, and to escape as such from the Gay-Lussac tower; and if chambers be worked so as to render the first rather than the second disadvantage more likely to occur, any loss thus arising would be lessened if the nitric acid required to make up the unavoidable losses in the system, were fed in at the Gay-Lussac instead of at the Glover tower; for the nitric acid would convert any nitrosulphuric acid into the much more stable nitrosulphuric acid.—J. T. D.

Nitric Acid; Manufacture of.—F. Winteler. Chem.-Zeit. 1905, 29, 820—823.

THE stringent demands of the modern consumer of nitric acid are very difficult for the manufacturer always to comply with. The chief use of nitric acid is in the explosives industry, and there, a highly concentrated acid, very free from nitrous acid, is needed. A similar acid is needed for the artificial silk and celluloid industries, while the manufacturer of organic dyestuffs is content with an acid more easily obtainable. Analyses of two samples of mixed acid for nitroglycerin or gun-cotton manufacture are given by the author:—

Total acid	96.303	97.267
Total nitrogen acids	34.28	36.357
Nitric acid	34.18	36.18
Nitrous acid	0.137	0.077
Sulphuric acid	62.01	61.01
Solid residue	0.132	0.05
Lead sulphate	0.033	—
Water by difference	3.56	2.68

These are American samples; the mixed acids are there usually made by adding "oleum" (sulphuric acid containing anhydride) to highly concentrated nitric acid sulphuric acids. In making such a mixture the nitric acid must not contain too much water, or the heat evolved will cause decomposition with formation of nitrous acid.

Pure nitric acid cannot be distilled at the atmospheric pressure without decomposition. Volney, in 1898, publishes the following figures showing the extent to which the reaction $2\text{HNO}_3 = \text{N}_2\text{O}_5 + \text{O}_2 + \text{H}_2\text{O}$ occurs at different temperatures:—

* C.	Per cent.	* C.	Per cent.
86	9.53	100	49.34
100	11.77	220	72.07
130	18.79	250	93.03
160	28.96	256	100.00

Hence dry nitre and concentrated sulphuric acid will not yield the most concentrated nitric acid unless the temperature of distillation be carefully kept low; while, by keeping it low enough, highly concentrated acid may be prepared from materials containing more water. It is to be remembered that the hydrates of nitric acid boil at higher temperatures than the acid itself, and are formed with evolution of heat; so that rise of temperature above the b. pt. of the pure acid may easily occur, with a composition of the acid, and formation of these hydrates and of nitrous acid, unless the distillation be very carefully watched. Vacuum distillation has been often attempted but the difficulties in the way seem to have prevented from being generally adopted. The best yield of highly concentrated acid is obtained in practice, if 92 per cent. sulphuric acid, not a stronger acid, be used in the distillation. The same remark applies to the distillation of mixed (nitrosulphuric) acid. The conditions are summarised as follows:—1. The distillation-temperature must be kept as low as possible, and, to avoid overheating the distillation must be conducted slowly; the time necessary will be determined by the size and form of the retorts. 2. With dry nitre, the sulphuric acid used should be of the strength of 92 per cent. 3. Introduction into the retort of atmospheric oxygen improves the yield. 4. Issuing vapours should be condensed as rapidly as possible.

To complete the decomposition, and leave a nitrogenous bisulphate in the retort, the temperature must be raised to obtain a free-flowing bisulphate $160^\circ\text{--}170^\circ\text{C}$. is the best temperature. Even at 250° , however, traces of nitrate or nitrite still remain; and these traces are increased, contrary to what might be expected, if excess of sulphuric acid be added. If the bisulphate be used to produce hydrochloric acid, excess of sulphuric acid makes it very hygroscopic, almost impossible to store, and difficult to grind. Moreover, it causes evolution of hydrochloric acid even in the cold on mixing with water and hence nuisance and loss. The traces of nitrogen acid in the bisulphate produce chlorine in the hydrochloric acid; and through the continual regeneration of higher oxides with the aid of atmospheric air, the amount of chlorine gradually increases in the acid when stored, and may render it useless for some purposes. The sudden foaming of the bisulphate at about 150°C ., when the water of hydration is given off, is another difficulty of the process and can only be overcome by using sufficiently capacity retorts and exit tubes.

The chief impurities in nitre are chlorides and small amounts of iodine compounds. The chlorides yield chlorine and nitrosyl chloride; and if the mixture of nitre and acid be made before putting it in the retorts which case closed vessels with a draught must be used, these gases escape, and produce no effect beyond the loss

nitric acid corresponding to the nitrosyl chloride. Most of the iodine remains in the retort as sodium iodate; but some goes over, and give a yellow tint to the acid. The iodine in the retort is in turn the source of iodine in the hydrochloric acid made from the bisulphate. Selenium arsenic in the sulphuric acid become sodium selenate and arsenate, and do not contaminate the nitric acid. They go over, however, from the bisulphate into the hydrochloric acid, and the selenium colours the acid brown or reddish. Hydrochloric acid containing selenium attacks and dissolves copper, the selenium acting catalytically. In condensing the vapours issuing from the retort, fractional cooling is a promising plan as a means of separating the more easily condensable hydrates of iodine acid from the less easily condensable anhydrous iodine.—J. T. D.

Carbonate; Decomposition of — by Alkali Chlorides in Presence of Water. A. Cantoni and J. Passanunzi. *Ann. Chim. anal. appl.*, 1905, 10, 258—262. *Chem. Centr.*, 1905, 2, 535—536.

TRON and Goguelia (this J. 1904, 440; 1905, 88) have previously studied the decomposition of alkaline-earth carbonates by aqueous solutions of alkali chlorides. The investigation has now been extended to the case of zinc carbonate. The action of ammonium chloride solution on zinc carbonate is almost independent of the duration of the action, but increases very rapidly with the temperature and with the concentration of the solution. Zinc carbonate is only slightly attacked by solutions of potassium chloride or sodium chloride, but is much more soluble in these solutions than in pure water. A N/1 solution of ammonium chloride dissolves at 14° C. 0.0586 gm., and a N/1 solution of potassium chloride, 0.04768 gm. of zinc carbonate per litre; whereas Essen found that water at 15° C. only dissolves 0.01 gm. of zinc carbonate per litre. —A. S.

Ammonium Salts; Variation of Basic function in —. A. Colson. *Comptes rend.*, 1905, 141, 331—333.

The author considers that the hydroxide precipitated from chromic acid is $\text{O} \cdot \text{Cr}_2(\text{OH})_4$. This is confirmed by the fact that one molecule of it, dissolved in molecules of acetic acid behaves thermodynamically, adding successive molecules of potassium hydroxide, as though it contained two molecules of acetic acid, and, on evaporation *in vacuo* over phosphorus pentoxide, gives the composition $\text{O} \cdot \text{Cr}_2(\text{C}_2\text{H}_3\text{O}_2)_2 \cdot 2\text{H}_2\text{O}$. This reaction is not at once decomposed on addition of the requisite amount of potassium hydroxide; at 6° C. the liquid remains clear for many days, at 20° for several hours, at 30° for some minutes. The hydroxide so precipitated is dark green and gelatinous, quite different from that precipitated from chromic acid, which latter, too, is a strong base, liberating from a solution of potassium salt enough hydroxide to make the liquid alkaline to litmus or nolphthalein. Possibly the addition of potassium hydroxide to the tetracetate gives at first potassium compounds which then react on one another

the dissolved salts of chromium, as well as the hydroxide, exhibit these changes; the green sulphate, for example, obtained by reducing chromic anhydride by sulphurous acid, slowly changes in density, and in heat of decomposition by potassium hydroxide.—J. T. D.

Gases Issuing from Pyrites Burners; Treatment of —. Gases; Means for removing dust from —. J. Shields, London. Eng. Pats. 16,353 and 16,354, July 23, 1904.

THE gases, especially those from pyrites burners, are conducted beneath or into a constantly replenished heap of porous or granular material, such as coke, crushed slag, or the like, which, as it collects the dust, is drawn away from the bottom of the heap by a conveyor, and is elevated to pass into a separator for the removal of the dust, and then restored through a funnel hopper in a clean, hot state, to the top of the heap. The receptacle for the filtering material is of conical shape, with its apex downwards, and about the centre of the heap the gases are led in through a pipe immediately under a horizontal disc, beneath which a cavity is thus maintained. Another form of apparatus is also shown, in which the filtering material falls slowly between sets of inclined shelves arranged in a cylindrical or rectangular form.—E. S.

Sulphuric Acid; Construction of Plant for the Manufacture of —. G. E. and A. R. Davis, Manchester. Eng. Pat. 20,012, Sept. 16, 1904.

THE flues connecting the chambers in sulphuric acid plant, instead of being made as is usual, large in sectional area, are under the present invention, constructed in series of 40, more or less, and of diameter varying from two to three inches, their number, length and diameter being, however, proportioned to the work required from them, and the pressure under which they are to be worked. Such tubes, being exposed to the atmosphere, are stated to be efficient coolers.—E. S.

Kilns for Burning Limestone, Dolomite and the like. E. Schmatella, Berlin. Eng. Pat. 4245, March 1, 1905.

THE kiln is mainly characterised by the arrangements for the introduction and distribution of the gas from a producer, and of air. The gas passage communicating with the generator extends through the base of the kiln, and is closed by a plug. Branches lead from this passage into lateral ducts, whence the gas passes to inlets in the walls of the kiln shaft. The supply of gas is regulated by dampers in the ducts; outside these are other ducts for admission of air, opening at their upper ends into air spaces having gratings or regenerative passages, formed by rhomboid projections on the firebrick lining of the shaft. The air thus cools the lining while being itself heated. A funnel-shaped iron ring is arranged in the lower part of the kiln shaft, projecting towards the centre. Air enters the annular cavity below this ring, from which, thus heated, it rises into the burning zone, whereby a long flame is obtained.—E. S.

FRENCH PATENTS.

Hydrochloric and Hydrobromic Acids; Manufacture of —. E. F. J. Hoppe. Fr. Pat. 352,419, March 15, 1905.

THE elements of hydrochloric or of hydrobromic acid are brought together in a moist and heated state in the presence of such metal chlorides or bromides as are decomposed by heat in the presence of water. Aluminium, zinc, and tin chlorides (or bromides) are mentioned, among others, as suitable agents for effecting the required synthesis. A temperature of about 100° C. usually (but not in all cases), suffices for the reaction.—E. S.

Sulphur Dioxide and Carbon Dioxide; Processes for the Recovery of —, in the Treatment of Sulphide Ores, of Sulphates, or of Sulphur Compounds generally; as well as Methods for the Production of Nitrogen. H. S. Elworthy and D. Lance. Fr. Pat. 352,254, Feb. 18, 1905.

SULPHATES of the heavy, alkaline-earth, or alkali metals,

are heated with carbon in a closed vessel, in a complete or partial vacuum, and the mixture of carbon monoxide and dioxide formed, is led, for instance, through copper oxide heated to redness, as directed in Eng. Pat. 25,907, of 1897; this J., 1898, 908) whereby the carbon monoxide is oxidised, and the copper oxide is reduced to metal, with recovery of pure carbon dioxide. Air is then led through the heated metal, to reproduce the copper oxide. The nitrogen remaining from the reaction, between air and heated copper is claimed as being available in the synthesis of ammonia and of cyanides, &c.

Sulphides, natural or artificial, are heated in a closed vessel, into which air is injected, to produce sulphur dioxide, which may be liquefied, or converted into sulphuric acid. But, preferably, the sulphides are heated in a converter, lined with magnesite or the like, while air is passed in, whereby sulphur dioxide is produced, and fixed oxides are formed. A combination of processes is adopted in certain described cases. Reference is made to Fr. Pat. 342,865, of 1904; this J., 1904, 1032;—E. S.

Leucite, Industrial Treatment of — (for Obtaining Aluminium Hydroxide, &c.). Soc. Romana Solfati. Fr. Pat. 352,275, March 10, 1905.

THE main object of the invention is to obtain from leucite and like minerals the aluminium as hydroxide, with a potassium salt as an accessory product. The mineral is mixed with sodium hydroxide, carbonate or nitrate, and oil-soluble, and the mixture, after roasting at a dark red heat, is leached, and steam is passed through the solution to oxidise any ferrous salt. The solution, containing sodium aluminate and potassium carbonate, the silica having combined with the lime to form an insoluble silicate, is treated by any usual process to obtain aluminium hydroxide as a precipitate, and the alkali carbonate in solution. The residue, containing the double silicate of sodium and calcium, is treated with sodium bisulphate to dissolve out the soda as sodium sulphate. *See also* U.S. Pat. 744,765 of 1903; Eng. Pat. 23,919 of 1903; and Eng. Pat. 377,616 of 1901; this J., 1903, 1347; 1904, 1896, and 1905, 276;—E. S.

VIII.—GLASS, POTTERY, AND ENAMELS.

ENGLISH PATENT.

Glass, Manufacture of Sheet —. P. T. Sievert. Dresden, Germany. Eng. Pat. 9211, May 2, 1905. Under Int. Conv., April 12, 1905.

THE process consists in drawing sheets from a uniformly heated mass of glass. The uniform mass is obtained by supplying glass from a tank to a smaller reservoir, evenly heated on all sides and top and bottom, which is separated from the actual drawing chamber by a partition, and communicates with it at a point below the surface of the molten glass. The actual drawing chamber is covered, and in the cover is a slot, through which the sheet is drawn by suitable means, and which is at such a level that the molten material just enters it.—W. C. H.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Firebrick; Action of Blast-Furnace Gases on —. T. Ludwig. X. (see below).

Cement; Detection and Determination of Free Blast-Furnace Slag in —. M. Garity. XXIII., page 942.

ENGLISH PATENTS.

Kilns for Burning Limestone, Dolomite and the like. E. Schmatolla. Eng. Pat. 4215, March 1, 1905. VII., page 925.

Cement; Grinding Apparatus for Manufacturing —. E. J. Clarke, Greenluthie, Kent. Eng. Pat. 6391, March 25, 1905.

THE invention relates to an apparatus for grinding

"slurry," namely, the liquid mixture of chalk, clay and water. It consists of a brush of stiff wires, which is made to rotate by suitable means over the surface of a block. A cup-like opening is provided at the centre of the brush into which the material to be ground is fed. A casing surrounds the brush and block and has an opening for the exit of the material treated. Means are also provided for raising the block to allow for the wearing away of the brush. The grinding and mixing are effected by the passage of the material through the brush and over the block.

—W. C. H.

Oleaginous Mixture for Sprinkling on Roads and the like. R. M. Hahn, London. Eng. Pat. 11,620, June 2, 1905.

A SUITABLE oil is first mixed with $\frac{1}{4}$ to 1 per cent. carbolic acid, which produces an emulsion, and is then heated to, say, 150° F., and mixed with about 5 per cent. of asphaltum, 10 to 15 per cent. of tar, and, say, 5 per cent. of the residue from the distillation of glycerol. Using the mixture the road is first sprinkled with the product diluted with 3 parts of water, whilst for subsequent treatment the water may be increased to 10. It is claimed that a sprinkling once a month in summer and once in three months during the remainder of the year, keeps a road moist and absorbent of dust, with level, compact surface like asphalt.—C. A. M.

UNITED STATES PATENTS.

Asbestos Composition. H. C. Todd and C. Mayr, Chicago, Ill. U.S. Pat. 796,164, Aug. 1, 1905.

SHEETS or articles are prepared by making a mixture powdered aluminium silicate, sodium silicate, and water, which is used to impregnate, and fill the spaces between asbestos fibres, and the articles formed are dried, and finished at a temperature of about 800° F. or less.—W. C.

Stone; Process for Treating —. H. Ryan, Seattle, Wash. U.S. Pat. 796,253, Aug. 1, 1905.

THE invention relates to a process for strengthening or improving the colour or quality of stone. Stone, when permeated with iron-rust, is subjected to the action of more or less dilute phosphoric acid for any length of time that may be necessary, and the excess of acid is afterwards removed by washing with water. Stone may then be subjected to the action of "sugar of lead" which is allowed to dry, and then a solution of phosphoric acid is applied and finally the excess of "sugar of lead" and phosphoric acid is removed by washing.—W. C. H.

FRENCH PATENTS.

"Artificial Trass"; Manufacture and Application of a New Industrial Product called —. A. Cajot. Pat. 352,351, March 14, 1905.

A NEW industrial product called "Artificial Trass," is made by adding a certain quantity of lime or carbonate of lime to blast-furnace slag while in an incandescent state; a quantity of lime, &c., added depends upon the composition of the slag, and varies inversely with the content of lime and alumina in it. The product is then granulated by a dry process. The claims also include this process of manufacture of the new product, and its use in place of natural trass in different mortars.—W. C. H.

Hydrocarbon Oils; Emulsifying — by Marine Alkali. H. M. L. D'Azémar. Fr. Pat. 352,100, Feb. 15, 1905. III., page 919.

X.—METALLURGY.

Blast Furnace Calculations. J. L. Stevenson. Eng. Pat. 1905, 100, 177—178.

CALCULATIONS are given for designing a new blast-furnace plant, as also for the power required. A summary of the power required for any output per furnace is likewise given.—A. S.

Firebrick; Action of Blast-Furnace Gases on —. T. Ludwig. Stahl u. Eisen, 1905, 25, 870—872.

FIRESTONE (this J. 1904, 442) recently drew attention to the case of the destruction of firebrick by blast-furnace gases.

I published some analyses of the brick. The author puts out that at the relatively moderate temperatures aimed in the blast furnace, it is highly improbable that alumina would be lost or gained by the firebrick, by ion or vaporisation, and that consequently more doubt should be thrown on the problem by regarding the amount of alumina in the brick as fixed, and calculating the relative increase or decrease of the other constituents on this basis. This method was applied to Firmstone's analytical figures, with the following results:—

	Brick before use, Col. 4 in Firmstone's table.	Brick after use, Col. 2 in Firmstone's table.	Glazed skin on brick, Col. 1 in Firmstone's table.
Alumina	1.000	1.000	1.000
Silica	2.453	3.096	5.597
Iron oxide	0.153	0.167	1.099
Magnesia	0.011	0.014	1.591
Potassium oxide	0.016	0.009	0.899
Sodium oxide	0.027	0.089	0.874
Lime oxide	0.012	0.027	1.135

In the body of the brick there was thus a notable increase in the proportions of silica and alkali, but the content of alumina, magnesia and iron oxide had not appreciably altered. The glazed surface, on the other hand, there was a considerable increase in the proportions of all the constituents other than alumina. With respect to the alkalis, magnesia and iron oxide, Seger and Cramer have shown that these substances are volatile to quite an appreciable extent at the temperature of the blast-furnace, but the increase of silica cannot be so readily explained. The author suggests that possibly a volatile cyanogen compound of silicon is formed, analogous to the halogen compounds of silicon.—A. S.

Use of Cyanide Solution.—by Wood from Potassium Cyanide Solution. S. Herbert Williams, Inst. of Mining and Metallurgy, Bulletin No. 11, Aug. 17, 1905.

900 TONS of solution (strength=0.007 KCN) from precipitating boxes, containing gold of a total value of 10 dols., flowed through a wooden launder 75 ft. long, 18 in. deep, 8 in. wide, inside measurement, during a period of seven months. On being discarded, the launder was burnt and the ashes, cleared from nails and screws, weighed 159 lb., and contained 2.766 oz. of gold and 464 oz. of silver, equal to 941.11 dols. per ton. The wooden launder contained 15.5 cb. ft. of wood and thus had an average value of 60.65 dols. per cb. ft.—J. H. C.

Cyanide-Process] *Use of Sodium Bisulphate in the Cleanup*. J. E. Thomas and G. W. Williams, J. Chem. Met. and Mining Soc. of S. Africa, 1905, 5, 334—337.

The authors have made a lengthy series of experiments with a view to determining the following points:—

- 1) Comparative rates of solution of zinc in equivalent solutions (i.e., as expressed in grms. of sulphuric acid : 100 c.c.) of sulphuric acid and sodium bisulphate.
 - 2) Maximum working strength of the bisulphate solution.
 - 3) Maximum strength of the stock solution.
 - 4) Effect of temperature, electrolytic couples, &c.
- Tables are given showing that "within limits" the bisulphate is slightly more efficient than commercial sulphuric acid of equal strength; stock solutions containing up to 20 grms. of free acid per 100 c.c. could be readily prepared, and working solutions, containing grms. of free acid per 100 c.c., could be used without any fear of crystallisation of the sodium bisulphate. The effect of the presence of metallic electrolytic couples was shortened the time required for solution of the zinc. Rise in temperature above 33° C., had the effect of lowering the solubility of the salt, and so putting an end to the solvent action.—J. H. C.

Cyanide Process] *Cyaniding of the Tailings: Some Suggestions on the* —. A. Prister, J. Chem. Met. and Mining Soc. of S. Africa, 1905, 5, 338—341.

The author having experimented on a scale of 280 tons of

sand at a time with a view of a certain amount of gold is actually dissolved in the tanks, proper care was taken of circulating the solutions based upon the fact that the gold is mainly dissolved by the strong solution, the weaker solutions following serving mainly to wash out the dissolved gold. By the method proposed, the same or better extraction is obtained, together with other advantages, viz., by the use of a quantity of solution one-fifth less than that generally employed.—J. H. C.

[Cyanide Process] *Cyaniding of Concentrates by Potassium Cyanide*. Notes on the —. A. L. Edwards, J. Chem. Met. and Mining Soc. of S. Africa, 1905, 5, 345.

210 tons of concentrates assaying 60 dwt. to the ton, at the Clutha Gold Mines, Barberton, were ground in a ball mill so as to pass through a 1600-mesh standard screen and leached by percolation after addition of 4 lb. of lime per ton of concentrates; a 0.05 per cent. potassium cyanide solution was run through and then a 0.1 per cent. solution. The concentrates were afterwards turned over and a 0.75 per cent. cyanide solution was run on and allowed to remain for 12 hours. This solution was then drawn off and all dissolved gold washed out as rapidly as possible; the treatment was repeated on three subsequent occasions during 40 days, whereby an extraction of 93 per cent. was secured. Had the concentrates been more finely ground 30 days would have been sufficient.

The cost for cyanide was 12s. per ton, zinc 4d., lime 3d., labour (exclusive of power costs) 5d. The high consumption of cyanide was owing to the unroasted state of the concentrates. The author concludes that concentrates can thus be treated locally for 40s. per ton, as compared with £6 18s. per ton, the cost of chlorination (including freight, 21 per ton).—J. H. C.

Alloys: Gold-Tin —. R. Vogel, Z. anorg. Chem., 1905, 46, 60—75.

The author has made a study of gold-tin alloys similar to that previously made of gold-lead alloys (this J., 1905, 518). The alloys containing from 0 to 20 per cent. of tin when rapidly cooled, contain three distinct structural elements, viz., grains of gold enclosed in mixed crystals of gold and tin, and an eutectic consisting of mixed crystals and the compound AuSn. If the alloys be cooled slowly, no separation of gold occurs. In the alloys containing from 20 to 60 per cent. of tin, the compound AuSn separates first, whilst the eutectic consists either of a mixture of mixed crystals and AuSn, or of AuSn and AuSn₂, according to the amount of tin present. When the proportion of tin in the alloys is from 60 to 80 per cent., the compound AuSn₂ separates first, and the eutectic consists of AuSn₂ and AuSn₄. In the alloys containing from 80 to 90 per cent. of tin, crystals of the compound AuSn₄ and in those containing from 90 to 100 per cent. of tin, crystals of metallic tin separate, the eutectic in both cases consisting of AuSn₄ and tin. With most of the alloys an abnormal crystalline structure is produced by rapid cooling.

The compound AuSn can be prepared by fusing together the necessary amounts of gold and tin; its formation is accompanied by slight expansion. It melts at 418° C. It has a bright, silver-grey fracture and is distinguished from its components, gold and tin, by its brittleness and hardness. It resembles gold in its resistance to the action of acids, and its electric conductivity surpasses that of all other gold-tin alloys, with the exception of those containing from 0 to 5 per cent. of tin. The compound AuSn₂ melts at 308° C. with decomposition into crystals of AuSn and a liquid, according to the equation:—

The crystals of AuSn₂ are as resistant to acids as those of AuSn. The compound AuSn₄ is softer and less resistant to acids than AuSn₂, but more so than pure tin. When heated to 252° C. it decomposes into crystals of AuSn₂ and a liquid, according to the equation:—

—A. S.

the hardest and most brittle of the compound is Sn_2 (its hardness is between that of cast-iron and that of malleable iron), whilst the toughest and softest is Na_2SiO_3 . —A. S.

Alum; Hardness of Wrought —. Werner v. Alten. Z. Elektrochem., 1905, 11, 503-504.

The author gives details of further tests upon the hardness of metal in the purest form that has yet been attained, after hammering out into sheets at a red heat.

The results obtained show that tantalum, containing very small amounts of oxide as impurity, after hammering into sheets at a red heat, is equal in hardness to the best and most carefully finished steel. Tantalum, however, greatly exceeds this hard steel in toughness, whilst these hard tool steels are brittle, tantalum can be drawn into sheets without injury. The new metal in its purest state, unites, therefore, the hardness of heat-treated steel, a greater toughness and ductility than is known to be possessed by any other metal. —J. B. C. K.

Deposition; Chemistry of —. Precipitation of Copper by Natural Silicates. E. C. Sullivan. J. Amer. Chem. Soc., 1905, 27, 976-979.

The author carried out a series of experiments on the deposition of copper from its solutions by finely-powdered solid substances. The solid substances used were kaolin, a shale from Arizona, consisting largely of quartz and glauconite, two specimens of orthoclase from Diego County, California, well-crystallised albite from Amelia Court House, Virginia, crystalline microcline from Wilmington, Delaware, and pyrites. Twenty-five grams of the finely-powdered solid substance were added to 100 c.c. of the copper solution (in most cases a 1 per cent. solution of copper sulphate crystals), and after the mixture stood for some time in a stoppered flask with occasional shaking, it was filtered and the filtrate analysed. It was found that the reaction between the silicates and the copper solution was mainly an exchange of bases, the copper being removed from the solution and an equivalent quantity of other bases (chiefly the alkali and alkaline earth bases) being dissolved. If "adsorption" takes place it is only in comparatively insignificant amount (see this J., 1905, 335). The amount of copper removed from the solution by a given solid substance depends upon the condition of fineness of the latter. The amount removed in one case 95 per cent. and in another case 100 per cent. of the copper from the solution. The feldspar, albite, and microcline, removed from 60 to 100 per cent. of copper from 50 c.c. of a solution containing 20 grms. of copper. Kaolin and pyrites were not so effective. —A. S.

Gold Solutions; Assaying —. A. M. Henderson. XXIII., page 942.

ENGLISH PATENTS.

Extraction [by Amalgamation]. W. H. Hyatt. C. Wick, Middlesex. Eng. Pat. 8677, April 15, 1904.

The old-hearing ore is delivered in fine powder into a hopper, from which it is fed into the pockets of a rotating cylinder within a casing excluding contact with air. As the cylinder rotates, its pockets come successively in contact with an amalgamating chamber or pipe below, through which opening the ore falls, and is swept forward by a blast of air along the pipe, which has downward and upward curves (U and \cap successively), mercury being introduced into the hollow of each downward bend. The ore is then drawn off under the influence of the air-blast from the hopper as it enters the amalgamating channel. The exit channel is provided with a device for trapping any excess of mercury that may be carried forward. Reference is made to Eng. Pats. 24,782 of 1894, and 16,032 of 1895; see this J., 1896, 119, and 1897, 805. —E. S.

Apparatus for Concentrating and Separating —. J. Huss, London. Eng. Pat. 15,793, July 15, 1904.

The apparatus consists of a travelling endless sheet or belt passing upon a diagonal grating, forming the concentrating table, is mounted upon a lower frame by

resilient supports, so that the two frames form a single self-containing frame of which the top is capable of receiving longitudinal movement, while the inclination of the whole may be adjusted to requirement. The top frame rests against adjustable buffer supports fixed by a standard, a cam mounted on which gives a periodic or bumping movement to the travelling table, a tension rod with spring, adjusting screw and hand wheel being attached at one end of the top frame. On a reciprocating motion may be imparted by means of an eccentric or "toggle" arrangement. An even sheet of water is supplied from a launder, which sheet passes over the transversely-inclined belt, and washes the lighter particles of the ore towards its lower longitudinal edge, whereby the ore becomes separated into bands of varying density. —E. S.

Copper and Alloys of Copper contained in Ashes, Sand and Waste from Foundries and other Works where Copper is dealt with; Process for Extracting and Refining the —. C. Casman, Brussels. Eng. Pat. 11,073, May 26, 1905.

The proportion of silica present in the copper waste having been determined, the quantity of sodium carbonate necessary to form therewith sodium silicate is added; or sodium chloride may partially or entirely replace the carbonate. The mass is then heated until the copper present fuses and sinks, the silicates produced forming a surface slag. —E. S.

UNITED STATES PATENTS.

Converters; Method of Lining —. C. M. Allen, Lolo, Mont., Assignor to R. Baggaley, Pittsburg, Pa. U.S. Pat. 796,169, Aug. 1, 1905.

The method consists in distributing silicious material on the interior of the converter, while its surface is covered with molten viscous slag or matte, and then applying molten slag or matte, as a cementing agent, and permitting the same to set, and cooling if necessary with an air-blast. —W. C. H.

Converter-Lining. C. M. Allen, Lolo, Mont., Assignor to R. Baggaley, Pittsburg, Pa. U.S. Pat. 796,170, Aug. 1, 1905.

CLAIM is made for a copper converter having air tuyères, and a distributed unpacked adherent interior lining of material containing silica. —W. C. H.

Copper-Converter. R. Baggaley, Pittsburg, Pa., and C. M. Allen, Lolo, Mont. U.S. Pat. 796,174, Aug. 1, 1905.

The claim is for a copper converter having a compacted silica lining and an interior lining of unpacked material containing ore. —W. C. H.

Matte; Converter for Bessemerizing —. R. Baggaley, Pittsburg, Pa. U.S. Pat. 796,175, Aug. 1, 1905.

The invention refers to a converter for Bessemerizing matte, which has an adherent lining, distributed and loosely arranged, of silicious material, sintered together throughout its mass. —W. C. H.

Matte; Method of Converting —. R. Baggaley, Pittsburg, Pa. U.S. Pat. 796,282, Aug. 1, 1905.

The method described for converting matte, consists in distributing the lining of unpacked silicious material, or ore, over the working area of the interior of the converter, sintering the same *in situ*, introducing matte into the converter, and then blowing air through the mass. (See also preceding abstracts, and U.S. Pat. 789,618 of May 9, 1905; this J., 1905, 624.) —W. C. H.

Metals; Pulverising —. H. Maxim, New York. U.S. Pat. 796,338, Aug. 1, 1905.

The metal to be pulverised is melted and run into a hopper discharging into a horizontal passage, in which it descends immediately in front of a blast of a highly heated inert gas, and the metallic spray formed is driven forward into a closed chamber, in which the spray is cooled by expansion of the gas, and also by a cooling liquid traversing the chamber in a pipe coiled, or bent to

and iron. The gas is pumped out of the chamber, part to be reheated, and part to be co-pressed for continued use to assist in cooling the chamber by its expansion. The "atomised" metal is collected.—E. S.

FRENCH PATENT.

Copper, Lead, Zinc, Nickel and Silver Ores: Concentration of — [Use of Oxalic Acid from Wood Distillation]. V. Laurent. Fr. Pat. 352,430, March 16, 1905.

The acid liquors obtained in the distillation of wood, are saturated with carbonate or oxide ores to form acetates. In the case of copper and silver acetates being obtained, these are distilled at about or under 300° C. to obtain crystallisable acetic acid, and a residue of the metal. Lead, zinc and nickel acetates thus produced are transformed into carbonates by an alkali carbonate, and the alkali acetate formed is treated by known means to recover acetic acid.—E. S.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(A).—ELECTRO-CHEMISTRY.

Electrolysis with Alternating Currents. E. Wilson. Paper read before the Faraday Soc., July 3, 1905. [Advance Proof.]

The author in this paper gives an account of some experiments made to determine the effects of electrolysis with alternating currents, upon certain metals and electrolytes. The potential differences between the electrolyte and one electrode were observed by means of a method described in the paper, and the curve of current intensity was also obtained by a special method suited to the conditions of the experiment. The results are exhibited in the table on page 931.—J. B. C. K.

Iron Salts; Oxidation and Reduction Processes in the Electrolysis of Solutions of —. Z. Karaslanoff. Z. Elektrochem., 1905, 11, 489—496.

The author has investigated the oxidation and reduction processes in the electrolysis of iron salts, especially with regard to their relation to the construction and reliability of a voltameter or coulomb-meter in which iron salts are used in place of the usual copper or silver salts. The principle of such a cell for use as a current measurer consists in the titration of the ferrous salt formed by cathodic reduction and present at the end of the period of use, by means of potassium permanganate solution. The author's experimental trials of this cell related to the influence of concentration, temperature, cathode material and position, time, and movement of the electrodes upon the reduction occurring at the cathode. A series of tests carried out with this form of cell, gave a mean error of +0.23 coulomb as compared with a silver voltameter in the same circuit. The author, therefore, concludes that the iron titration coulomb-meter is sufficiently accurate for laboratory use.

—J. B. C. K.

Chlorates; Electrolytic Formation of —. F. Foerster and E. Müller. Z. Elektrochem., 1905, 11, 502—503

The authors reply to a recent communication by H. Sirk (see this J., 1905, 544). Sirk's experiments dealt with the influence of platinum as electrode material, when free hydrochloric acid is present; and to the preponderance of the second of the two reactions, given in earlier papers by Foerster and Müller, namely—

or the production of chlorate in the electrolytic cell (see this J., 1902, 1235; 1903, 417). The authors here assert that Sirk is in error, in considering that his experi-

mental proof that the presence of platinum will accelerate the speed of the reaction represented by the equation:

applies to the reverse reaction, and they re-assert the correctness of their originally expressed views as to changes occurring in the electrolytic chlorate cell. Their views are based upon the results of direct experiment, and prove that the formation of chlorate is primarily due to the reaction:—

and is only secondarily due to the reaction investigated by Sirk.—J. B. C. K.

Nitrites; Electrolytic Production of —, from Nitrate, especially with Silver Cathodes. E. Müller and F. Spitzer. Z. Elektrochem., 1905, 11, 509—515.

CONTINUING their former work (this J., 1905, 445) authors have investigated the cathode potential of the electrolysis of alkaline solutions of sodium nitrate and sodium nitrite, and mixtures of the two, with cathodes of spongy copper, silver and gold. The method of experiment was to record the cathode potential at successive intervals of time, using, in the first instance, a platinum cathode, then coating the platinum cathode with a smooth deposit of the metal in question, and adding successive quantities of the metallic salt dissolved in a liquid of the same composition as the electrolyte, and continuing the observations after each such addition. The results with silver are in general similar to those formerly obtained with copper, that is to say, with the smooth cathode the potential required for the reduction of the nitrate, at first below that for the reduction of the nitrite, soon rises above that remains there, whilst with the spongy cathode the potential needed to reduce the nitrate is uniformly below that needed to reduce the nitrite. The difference in the ease, however, is very much greater with silver than with copper, so that the reduction of the nitrate to nitrite can be carried very much nearer to completion before any reduction of nitrite to ammonia occurs. In an experiment with a cathode of spongy silver between anodes, nearly 4 grms. of nitrite were formed in three hours in a solution originally containing 23.1 grms. of nitrate and 27.5 grms. of nitrite, 96 per cent. of the current thus utilised; and when the original solution contained only 7.9 grms. of nitrate and 45 grms. of nitrite, of nitrite corresponding to 48.5 per cent. of the current was still obtained. Elevation of temperature was favourable to the yield of nitrite. A previously prepared spongy electrode did not work as well as one prepared during the process in the manner above described. The removal of this disability in the previously formed electrode is of importance, for there are great difficulties in the way of adding silver solution and forming the cathode of electrolysis, if the process is to be worked industrially. A fairly complete conversion of the nitrate present into nitrite is necessary, as otherwise the isolation of nitrite by crystallisation is impracticable. Gold cathodes, whether smooth or spongy, are not suitable for nitrite production, as with them the reduction of the nitrate to ammonia occurs at the same potential as and concurrently with the production of the nitrite.—J. T. D.

solid structure, by subjecting the materials to which they are composed to pressure and at the same time to the action of heat so as to render them incandescent. The process may be applied in the manufacture of electric dynamo or motor brushes of pure carbon or of lathes consisting of carbon and of copper films interleaved, or of carbon combined with metal coes, netting or strips.

—W. H. C.

Electrolyzers; Impts. in —. E. L. Bartelt, Bristol, Eng. Pat. 18,356, Aug. 24, 1901.

A RECTANGULAR tank is divided into a number of compartments by transverse partitions, each compartment containing a series of suitable anodes and cathodes. The form of electrode described consists of an ebonite plate with a rectangular portion cut away at the bottom, the anterior edges of the cut being grooved for the insertion of a sheet of platinum foil. The latter is held in position by a wire which is attached to the foil, and threaded through a hole in the top of the ebonite plate. The partition between each compartment is provided on one side near to the top with a recess or cut-away portion, from which one or more vertical passages lead downwards through the centre of the partition, and are turned at right angles into and near the bottom of the adjacent compartment. The end wall of the first compartment is provided with similar passages, which are supplied with electrolyte from a suitable pipe, and an outlet pipe leads from near to the top of the last compartment through the base of the latter; this arrangement promotes a good diffusion of the electrolyte. (See this J., 1905, 678.)—B. N.

Furnaces; Impts. in Electric —. The British Thomson-Houston Co., Ltd., London. From The General Electric Co., Schenectady, N.Y. Eng. Pat. 20,810, Sept. 27, 1904.

A CARBON tube, in the bore of which the articles to be heated are placed, is made with two end pieces of larger diameter, and with an intermediate portion smaller in diameter. The larger end pieces are covered with a roll of paper, and the space between the paper and the inner smaller carbon tube is filled with powdered titanium carbide. The larger end pieces fit into sockets in massive graphite or carbon pieces, which are connected to the source of electricity. The tube and layer of carbide are finally surrounded with a packing of refractory material, such as coke. When the furnace is heated, the paper chars, and the carbide sinters together forming a refractory non-oxidisable shell of considerable mechanical strength, which is a good conductor of electricity, non-hygroscopic, and which materially increases the life of the carbon tube.

—B. N.

Cells; Impts. in Galvanic —. W. Schenk, Berlin. Eng. Pat. 6650, March 29, 1905.

THE positive electrode, which is hollow, contains a quantity of the solid exciting material, and is provided with openings, the upper acting, when the electrode is in position, as an inlet for the solvent, and the lower as an outlet for the dissolved exciting material. The space between the two electrodes is divided into two chambers by an insulating partition arranged between the inlet and outlet openings in the hollow electrode, the solvent being introduced into the upper chamber, and the dissolved exciting material passing into the lower chamber which contains the depolarising material. An absorbent layer of blotting paper is placed between the electrodes, and projects into the filling chamber so that it becomes impregnated with the solvent as soon as the latter is introduced.—B. N.

Alloys; Some Observations on the Deposition of — from Mixed Solutions. C. B. Jacobs. J. Amer. Chem. Soc., 1905, 27, 972–976.

THE author recently had occasion, in the preparation of an

alloy intended to receive a lithographic transfer, to effect a simultaneous deposition of two metals, zinc and nickel in definite proportions and in the form of strongly adherent, finely crystalline metal, under conditions which the use of cyanide solutions or alkaline solutions precluded. Neutral sulphate solutions of the two metals with the addition of varying proportions of ammonium sulphate and ammonium chloride, were found to form most suitable electrolyte for the purpose, with two anodes of zinc and one of nickel, and with a rotating cathode. The chief difficulty was that of maintaining the difference in voltage between the two anodes and cathode, in order that the amounts of the two metals deposited on the cathode might be regulated. This accomplished by the use of two generators running at different voltages, namely, one at high voltage for the zinc which is the more electro-negative metal, and one at low voltage for the nickel anode, the current returning through the cathode and a common return wire to the generators. By means of this arrangement, and by varying the distances between the zinc anode and nickel anode respectively and the cathode, it was found possible to deposit the two metals in any desired relative proportions with no more than the ordinary attention required in electro-plating.

Some experiments on the deposition of copper and nickel from a cyanide solution with the aid of the arrangement described above, showed that it was possible from the same bath to obtain at will masses varying in colour from light yellow.—A. S.

Ores and like Substances [Electrical]; Process for separating Certain Constituents of —, and Apparatus therefor. F. E. Elmore, London. Eng. Pat. 11,738, June 15, 1904.

THE ore is pulped with a liquid, and the pulp is electrolysed by being, for instance, fed into a vat between two pairs of converging electrodes, of which a number of pairs are arranged in series vertically, there being devices for deflecting the rising particles from the descending liquid. The liquid if non-conducting may be rendered conducting by addition of, for instance, sulphuric acid. The bubbles of gas given off during the electrolysis attach themselves to certain particles of the ore, which float and become separable. As an alternative, the pulp may be contained in a vat having vertical electrodes near its bottom, in which case a stirrer is used. (See also Eng. Pat. 19,063; this J., 1904, 22.)—E. S.

Electrolytic Pots containing Fused Baths; Stopper for —. C. M. Hall, Niagara Falls. U.S. Pat. 796,325, Aug. 1, 1905.

THE tap-hole of the vat is provided with a plastic body of carbon, which is baked around a metal plug. The tapering metal plug projects some distance outside the vat and can be removed from the plastic body to open the tap-hole.—R. S. H.

Aluminium; Making —. A. G. Betts, Troy, N.Y. U.S. Pat. 795,886, Aug. 1, 1905.

THE process consists in refining an alloy containing aluminium, using a fused electrolyte specifically different from the alloy, but heavier than pure aluminium. The alloy forms the anode at the bottom of the bath, and the cathode is pure fused aluminium floating on the surface. The method is applied to the manufacture of aluminium from its ores by first reducing in presence of iron or

oxide and submitting the alloy thus obtained to refining process described above.—R. S. H.

er; Electrolytically Refining ——. A. G. Betts, Troy, N.Y. U.S. Pat. 795,887, Aug. 1, 1905.

SOLUTION of a monobasic non-oxidising acid containing (over salt of the same acid and an agent to prevent growth of nodules is used as electrolyte. The impure r containing bismuth forms the anode, and the silver is deposited on the cathode.

ie bismuth which dissolves is precipitated with allie lead, and the electrolyte regenerated by precipitation of the lead and dissolving silver to the required unit.—R. S. H.

autoclave claimed is constructed of several communicating vessels of small capacity, instead of the usual large one, together with the necessary steam coils, &c., means for injecting air, &c. The apparatus can be alternately closed and open to the atmosphere intervals, regulated according to the nature of the process and the pressure employed, so that new quantities of material can be introduced and the operation carried out as a continuous process under any required pressure. Very much larger quantities can be saponified in given time and, therefore, at a lower price than in usual autoclaves. Claim is made for the application of apparatus constructed on these lines to any industrial process involving chemical reactions under variable pressure.—C. A. M.

One" and "Stearine" in Mixed Fatty Acids; Process of Separating ——. F. Lanza. Fr. Pat. 352,337, March 1, 1905.

is made for a process of treating the mixed fatty acids with sulpholeic acid. The fatty acids are first divided, and then introduced into a bath of acidulated water (1° B.) into which has previously been introduced 10 per cent. of an aqueous solution of sulpholeic acid. The mixture is agitated for 30 minutes and allowed to stand for the same length of time, during which the acid rises to the surface, whilst the solid fatty acids form a deposit of fine crystals at the bottom. The

aliphatic acid, and pomace, and agitating 100 lbs. of water, 1 lb. of oleic acid with 50 lbs. of sulphuric acid and 100 lbs. of which is added little by little with precautions to keep the temperature constant, and the product is subsequently diluted with 1000 lbs. of water. A special form of apparatus in which the process may be carried out is also claimed.—C. A. M.

Candles capable of being completely consumed; Manufacture of ——. J. Birwald. Fr. Pat. 352,242, March 10, 1905.

With the object of preventing the waste of the ends left in the candlesticks, claim is made for a form of candles which can be placed one upon another in such wise that the flame is communicated from one wick to the other without interruption. The original candle A is placed in the candlestick, and when partially consumed is replaced by a new one, A', on to the top of which it is fitted by means of the joint a, b. The wicks c, c', are reduced in diameter at the point of juncture in order to prevent any variation in the size of the flame.—C. A. M.

Rosin Spirit, Pine Oils, and Oil of Turpentine. Examination of Oils of Turpentine. E. Valenta. Chem.-Zeit, 1905, 29, 807—808.

THE author has examined several specimens of rosin spirit as to their refractive index and rotatory power, and gives figures for two of them. The first was a crude oil, too dark for optical examination, which, after treatment with caustic soda, gave 91 per cent. of a golden-yellow distillate passing over up to 298° C. This had at 20°-5 C. a refractive index of 1.48168, and gave a rotation in a 100 mm. tube of +1.0. On fractionating, it gave the following results:—

Temp.	Vol. of Dist.	Refr. Index.	Rotation in 100 mm. tube.
168°—178°	45	1.47188	+ 0.0°
178°—188°	19	1.47799	+ 0.3°
188°—210°	17	1.48640	+ 2.3°
210°—275°	8	1.50251	+ 5.0°
275°—288°	2	1.52268	+ 16.0°

The colour deepened as the b. pt. rose. The second sample was a refined pinolene; this contained 41 per cent. of fractions boiling between 115° and 166° C. The original oil had a refractive index of 1.47809 and a rotation of +0.2; the eight fractions gave refractive indices rising from 1.45509 to 1.50774, the rotations from -2.2° to -4.6° at 176° C. b. pt., then lower lavo-, and finally dextro-rotations. Treating the fractions with caustic soda made practically no change in these figures. The fractions from 115° to 166° C. when used to adulterate oil of turpentine, could not be recognised by their optical characteristics, which are not far enough removed from those of turpentine. They give, however, a yellow coloration on shaking with aqueous sulphurous acid, whilst turpentine and petroleum oils do not. Pine oils and rosin oils give

this reaction, however, and though the latter do not come over below 160° C., the former do. To distinguish between pine oils and pinolene as adulterants of oil of turpentine, the author recommends treating the distillate below 160° C. with acetic anhydride and a drop of sulphuric acid, when pinolene gives an intense green colour; or, mixing one part with 1-2 parts of 6 per cent. solution of iodine in carbon bisulphide or carbon tetrachloride, and heating on the water-bath. An intense green to olive-green colour is struck by pinolene, none by pine oils, pure benzal distillates, camphor, or resin-oils.

Pine oils, known as inferior oils of turpentine, made from roots, stumps, pine wood, &c., by partial destructive distillation. They are yellowish oils with a sharp smell, not removed by treatment with alkali, come on much from a d, and irritate the skin much more than oil of turpentine does. They dissolve asphaltum which has been exposed to light much more readily than oil of turpentine does, even when they have been refined and redistilled. They have, on the whole, a higher refractive index than oil of turpentine, but act similarly to the latter on polarised light: they are chemically similar to oil of turpentine, but contain, in addition, empyreumatic products. These latter afford reactions by means of which pine oils can be detected in oil of turpentine. If equal volumes of oil of turpentine and a 1 per cent solution of auric chloride be shaken in a test-tube, before and after one minute's heating in the water-bath, pure oils of turpentine show separation of gold in the oily layer only, but pine oils and pinolene completely decolorise the aqueous solution. Another useful test consists in mixing 10 c.c. of the oil with 5 c.c. of 10 per cent. solution of potassium iodide and 10 c.c. of carbon bisulphide and shaking for one minute. Oils of turpentine give a yellow apocynus layer, and a raspberry-red oily layer; with pine oils the oily layer is yellowish-red, and with pine oil, petroleum, or resin oil more or less pale yellow. The constants and reactions of a number of oils of turpentine, &c., are given in a table.—J. T. D.

ENGLISH PATENT.

Varnishes for producing "Mat" Surfaces: Manufacture of — F. Wachendorf, Köln-Ehrenfeld, Germany.
Eng. Pat. 12,469, June 15, 1905. Under Int. Conv.
April 3, 1905.

THE admixture of a basic aluminium compound, such as aluminium hydroxide, basic aluminium silicate, or the like, with from 9 to 22 parts of a fatty drying oil varnish, yields a product containing aluminium compounds of the fatty acids present in the varnish or produced during the drying. This combination furnishes a "mat" varnish which does not become sticky, or show any tendency to soften. Owing to its complete homogeneity it remains elastic and free from cracks, and it is not attacked by water at ordinary temperatures. The claim is for varnishes of this character and the manufacture of the same.—M.I.S.

UNITED STATES PATENT.

Turpentine; Apparatus for Distilling — S. S. Fleming, Brunswick, Ga., U.S. Pat. 788,310, April 25, 1905.

THE finely ground wood is introduced into a barrel-shaped tank, mounted horizontally on hollow shafts capable of revolving in suitable supports. Through one of these shafts passes a steam-supply pipe, whilst from the other issues an outlet pipe with a funnel-shaped inner end secured to a strainer. The manifold for introducing and discharging the material is in the middle of the side. The amount of wood introduced should be insufficient to fill the tank so that when the latter revolves, it can move freely, thus enabling the steam to penetrate every part and obviating the necessity of distillation under pressure.—C. A. M.

FRENCH PATENTS.

Resin or Resinous Products; New Economical Furnace for Distilling — A. A. Lagrave, Fr. Pat. 352,109, Feb. 22, 1905.

THE system of flues is so disposed that the hot gases from

the fire can be conducted either under and round the proper or else to the preliminary heater, by opening and closing appropriate dampers. Passages in the brickwork enable any part of the flues to be cleaned as desired, and all the flues discharge into one stack.—C. S.

Manila Copal, Sandarac and other similar Resins; Process for Rendering — Insoluble in Oil, in view of the Application in the Preparation of Furniture Polishes — W. Baringer, Fr. Pat. 352,323, March 13, 1905.

MANILA copal, sandarac or similar resins soluble in alcohol are mixed with from 1 to 5 per cent. of a fatty oil, heated gradually till of a suitable consistence, and maintained in this condition for from a half to one hour with constant agitation. It is claimed that the resins after this treatment are insoluble in oil and may thus be used in the preparation of furniture polish.—A. S.

(C) — INDIA-RUBBER, &c.

Litharge and Vulcanisation. W. Esch, Gummi-Fabrik, 1905, 19, 977-978.

C. O. WEBER was of the opinion that the action of litharge in accelerating vulcanisation was due to its power of acting as a sulphur-carrier. Schulze (this J., 1904, 719), on the other hand, considered that this action was due to good heat conductivity of litharge and to its capacity for forming soap-like compounds with the rubber. According to Weber no vulcanisation of rubber is effected in a mixture containing litharge until some lead sulphide is formed, and, in support of this contention, he stated that heating two mixtures: (1) Para rubber, 100; litharge, 100; and sulphur, 3 parts; and (2) Mangabeira or African rubber, 100; chalk, 100; litharge, 10; and sulphur, 3 parts, for eight hours in hot air at from 130° C., the Para rubber was well vulcanised and sulphide was formed, whilst, with the other mixture the rubber was not vulcanised, and no lead sulphide produced. The author points out that the results of comparative tests are not at all conclusive, and states that lead sulphide cannot be the active agent in effecting vulcanisation, since if in the Mangabeira rubber mixture litharge be replaced partly or wholly by lead sulphide no vulcanisation of the rubber takes place. The results known appear to indicate that in consequence of reaction between the litharge and the caoutchouc the carbon of Para rubber, the absorption of sulphur by the latter is accelerated; the formation of lead sulphide is regarded as being due to a secondary reaction. It is pointed out that the action of litharge is not analogous to that of lime or magnesia, as is frequently stated. Mixtures containing large proportions of lime or magnesia are passed between the mixing rolls, the "heating effect" produced by litharge is not observed, and the resulting vulcanised rubber soon becomes hard and brittle. Over lime unites directly with sulphur at moderate temperatures to form polysulphides, which are known to be a direct vulcanising action, whereas at similar temperatures no reaction takes place between litharge and sulphur, whilst even if lead sulphide were formed, it has no vulcanising action.—A. S.

ENGLISH PATENT.

India-Rubber; Process for Devulcanising — J. B. Strup and A/S. Gummi-Regenerations-Societet, Eng. Pat. 2655, Feb. 9, 1905.

See Fr. Pat. 351,816, Feb. 25, 1905; following these.

UNITED STATES PATENT.

Caoutchouc; Process of Obtaining — from plants belonging to the Nettle Family. C. K. Roeder, Philadelphia, Pa., Administratrix of G. H. Roeder, Assignor to E. F. Greeff and A. Tilt, New York, and C. C. R. Yonkers, N.Y. U.S. Pat. 795,860, Aug. 1, 1905.

FROM the green stalks of the plant, the bark is separated by decortication, and the remaining fibrous constituents are subjected to moderate pressure to remove the juices and saps, washed free from woody and other impurities by means of water, and then treated with a suitable solvent for the extraction of the caoutchouc.—A. S.

FRENCH PATENT.

Process for Decalcinising ——. A/S. Gummi-Generations-Soc. (System-Resen-Steensrup). Fr. P. 251,816, Feb. 25, 1905.

invention relates to the regeneration of the rubber waste containing a backing or core of textile material, at previous separation of the latter. The waste is ground, and then heated under a steam pressure of 8 atmospheres, in a jacketed lead-lined boiler, with an agitator, with suitable proportions of alkali or alkaline-earth and hydrofluoric acid. After treatment the recovered rubber is washed and dried. The proportions of alkali or alkaline-earth and hydrofluoric acid required vary according to the respective proportions of sulphur and of textile material contained in the rubber waste. If the waste contains only a small proportion of textile material, the hydrofluoric acid may be added in the boiler, during the heating operation, in the proportion of 10 per cent. of sulphur and about 1 per cent. of textile fabric would require 5 per cent. of acid and about 5 per cent. of hydrofluoric acid, whereas if it contains only 1 per cent. of textile fabric, 1—2 per cent. of hydrofluoric acid or 1—3 per cent. of fluorspar would be sufficient.—A. S.

XV.—TANNING, LEATHER, GLUE, SIZE.

ENGLISH PATENT.

Treatment or Preserving of ——. A. A. Bailey, Cliftonbury, Somerset. Eng. Pat. 18,267, May 23, 1905.

with the natural wool or hair on them are treated with a "chrome liquor," which is applied to the smooth or hairless side only of the skin, and is not allowed to come in contact with the wool. The following formula is used to give good results:—Potassium bichromate, 1 lb.; hydrochloric acid, $\frac{1}{2}$ gallon; glucose, $1\frac{1}{2}$ —2 lb.; water, to 2 galls. When the skin has been completely impregnated with the liquor, it may be dried, pressed, scored, and dyed. Skins thus treated are found to be more pliable than those tanned by older processes.—M. J. S.

UNITED STATES PATENT.

Apparatus. W. R. Smith, Assignor to Buffalo Leather Co., Buffalo, N.Y. U.S. Pat. 795,942, Aug. 1, 1905.

apparatus claimed consists of a vat or series of vats adjacent to a liquid-storage tank. A circulating pump with suction and discharge pipes connects the storage tank with the bottom of the vats; the suction pipe being provided with an air-inlet which allows of the liquid being drawn during the pumping operation; the discharge pipe, at its lower extremity, has perforated radiating arms arranged so that the liquid in 2 horizontal directions and so imparting rotary movement to the solution.—M. C. L.

XV.—MANURES, Etc.

Retrospection of the Soluble Phosphates in Bone ——. G. Gray. Chem. News, 1905, 92, 77—79.

RETROGRESSION is slight in well-made superphosphates, but may be considerable when insufficient acid has been used, the unchanged tricalcium phosphate reacting with monocalcium phosphate to produce the dicalcium phosphate. Similar changes take place when superphosphate is mixed with certain other manures, sometimes added by mistake to improve the mechanical texture. The object of the present experiments was to ascertain the nature of the changes which occur in such mixtures as are known to have been used, and also the rate of the change. The experiments show that bone dust is the best form of calcium phosphate for mixing with superphosphate, the amount in the amount of soluble phosphoric acid being

only 2.8 per cent. in 18 days. Good results were obtained with kainite both reduced the soluble phosphate by 4 per cent. by 7 per cent. Chesterfield guano is found to require 1 per cent. of lime the reduction is very rapid, the soluble phosphate being reduced in 24 hours, and 94 per cent. in 10 days. Bone slag and ground limestone have been found to require 1 per cent. of lime (88 and 86 per cent. respectively). With bone-dust there is a great production of citric-soluble phosphoric acid due to the iron present.—N. H. J. M.

XVI.—SUGAR, STARCH, GUM, Etc.

Levulose; Conversion of Dextrose into, and the Identification of ——. H. Ost. Z. angew. Chem., 1905, 30, 1170—1174.

DIERSSEN (this J., 1903, 312) has shown that levulose is produced during the saccharification of starch by oxalic acid, owing probably to the secondary action of the acid on the dextrose. The author has effected a similar transformation of dextrose into levulose by the action of moderately strong sulphuric acid. 1.1 kilo of dextrose was dissolved cold in a mixture of 2 litres of water and 1 litre of concentrated sulphuric acid, and the solution was allowed to remain at the ordinary temperature for four months; it was then neutralised with chalk and concentrated at a low temperature. The syrup was fractionated by means of alcohol and ether, the final fractions being levo-rotatory. The author estimates that 100 parts of dextrose yielded approximately 20 parts of isomaltose, 5 to 10 parts of levulose, and 60 parts of recovered dextrose. The identification of levulose is very difficult; the most certain method is that of Dubrunfaut, applied to the syrups enriched in levulose after the fractional crystallisation of the dextrose. The levulose was precipitated from a 10 per cent. syrup at 0° C. by the addition of dry slaked lime. The calcium levulosate was separated with certain precautions, and the sugar was regenerated by the action of oxalic acid. The levulose was obtained in the crystalline form by careful concentration of the syrups and the addition of methyl alcohol and ether; it was identified by its high levo-rotatory power. The separation of the levulose from the dextrose by this method was by no means complete, a considerable proportion of it, together with traces of mannose, remaining in the dextrose liquors. Neuberg's reaction for levulose by the formation of the methylphenylosazone has only a limited value. Dextrose forms the same methylphenylosazone as levulose, only more slowly. If a considerable crystallisation of osazone occurs within 20 hours at the ordinary temperature in a 10 per cent. solution of the sugar, the presence of levulose may be inferred with certainty, but doubtful results are very easily obtained if the syrups be impure or comparatively poor in levulose.—J. F. B.

Saccharose, Maltose, Lactose and Raffinose; Quantitative Hydrolysis of ——. B. Pflüger and B. Linne. Z. Unters. Nahr. u. Genuss., 1905, 10, 104—110.

THE authors have investigated the conditions necessary for the quantitative hydrolysis of certain sugars, using for the purpose a pressure cylinder, consisting of a bronze tube about 30 cm. in height and of 3.2 cm. internal and 4 cm. external diameter. The tube is furnished at the upper end with a screw so that a head may be screwed on and rendered tight by lead packing. This head carries a side-tube provided with a manometer, and is furnished with a conical valve. The top of the head is closed by a screw cap tightened by means of lead. Inside the cylinder is fitted a thick-walled glass tube, constricted at the upper part and provided with a mark. By joining the apparatus with a cylinder of carbon dioxide, any pressure up to 50 atmospheres can be maintained in the tube. During the hydrolysis the cylinder is suspended in a glycerin bath so that the liquids are at the same level, inside and out, the temperature of the bath being kept constant by a regulator.

When saccharose is hydrolysed by mineral or organic

acids, it is impossible to complete the hydrolysis without destroying some of the monosaccharides formed, but the authors find that, without acid, saccharose is quantitatively hydrolysed in 2½ hours when subjected to a temperature of 125° C. and a pressure of 20 atmospheres produced by carbon dioxide; the invert sugar remains unaltered after a further period of half an hour. Under the above conditions neither dextrin, nor maltose, nor lactose undergoes change.

Raffinose is completely hydrolysed into melibiose and levulose when subjected for three hours to the action of carbon dioxide at a pressure of 20 atmospheres and a temperature of 125° C.

Investigation of the action of acids on maltose and invert sugar shows that those acids which have the least action on invert sugar, e.g., acetic, succinic, glycollic, &c., hydrolyse maltose to a very slight extent. The best acid to use for the hydrolysis of maltose is benzenesulphonic acid in 2 per cent. solution, the hydrolysis being quantitative after 2½ hours at 110° C. When saccharose or invert sugar is subjected to these conditions, 17 per cent. of it is destroyed, this proportion being independent of the concentration of the sugar solution or the magnitude of the pressure. The conditions for the quantitative hydrolysis of lactose are the same as those for maltose.

The methods above described can be employed for the determination of the purity of sugars, and for the determination of sugars in presence of one another, as, for example, in honey, condensed milk, &c.—T. H. P.

ENGLISH PATENT.

Carbohydrates: Caramelisation of —. C. H. K. Genville and J. W. Jarvis, Stratford. Eng. Pat. 20,166, Sept. 19, 1904.

GLUCOSE or other carbohydrate is melted to a syrup and the syrup is run into another vessel, where it is mixed at the atmospheric pressure with ammonia, in solution or otherwise, without the application of heat. The mixture is transferred to a third vessel, in which it is heated with agitation to a temperature of about 220° F., at about which temperature, and at about atmospheric pressure, it is maintained until caramelisation is sufficient. —J. F. B.

FRENCH PATENT.

Sugar: Malaxeur with Rotating Internal Temperature Interchanger for the Manufacture of —. J. Labourbe. Fr. Pat. 352,135, March 6, 1905.

IN the malaxeur described and figured, the essential peculiarity is the arrangement, round a hollow axis rotating in a horizontal vat, of radiating arms which form a helix and which are hollow, so that hot or cold liquid, admitted at the extremity of the axis, can spread through all the arms and so maintain the saccharine mass at any desired temperature.—T. H. P.

XVII.—BREWING, WINES, SPIRITS, Etc.

Mucor Fermentation. Wehmer. Ber. deut. botan. Ges.; through *Brewers' J.*, 1905, 41, 518.

IN the case of the mucorine, e.g., *Mucor javanicus*, *M. spinosus* and *M. racemosus*, the power of producing alcohol is inherent in the mycelium as well as in all other cells of the organism. The alcoholic fermentation induced by *M. racemosus* is entirely independent of the presence of gemmae. The formation of gemmae is an anaerobic phenomenon, but the alcoholic fermentation proceeds with or without the presence of air, and the production of gemmae is rather the result than the cause of alcoholic fermentation, since it only takes place in the presence of a fermentable sugar. The growth of the fungus is restricted by the presence of 3 to 5 per cent. of alcohol, but in the

course of some weeks nearly one-half of this alcohol is consumed by the organism.—J. F. B.

Sarcina: Question of the Transmutability of Genuine into Beer Pediococci. N. H. Claussen. Amer. Brewer, 1905, 41, 529—530.

THE author defends his contentions (this *J.*, 1904, 32 and 876) on this question, against criticisms by Schönfeld and reaffirms that the pediococci which produce the so-called sarcina sickness of beer are absolutely distinct from the genuine sarcina or the pediococci which thrive in alkaline liquids. The beer pediococci are essentially anaerobic organisms which cannot be cultivated in ammoniacal yeast water, whereas the real sarcinae are aerobic organisms which it is impossible to cultivate in an acid medium such as beer. In the author's list of the beer pediococci, *P. pernicius* and *P. damnosus*, there is no tendency to racial variation, and are remarkably constant and well characterised species. These dangerous and specific organisms will escape detection in ammoniacal yeast water be employed in the examination of the suspected beer; on the other hand, non-aerobic forms of genuine sarcina will be found, but well authenticated evidence has been produced to show these forms ever existed in the original beer, still less they were the cause of disease. The various theories of virulence, acclimatisation and transmutability of sarcinae which have been adduced to account for the sickness of beer, are based, according to the author, on errors arising from aerial infections during the investigations, and from the use of an alkaline culture medium totally unfit to afford conclusions relative to aerial product such as beer.—J. F. B.

Yeast Mashers [Distillery]; Lactic Acidification of —. W. Henneberg. Z. Spiritusind., 1905, 28, 261—262, 271—272, 281—282.

EXPERIMENTS on the laboratory scale with pure cultures of *B. Delbrücki* showed that the production of acidity is rapid, and proceeds to a high degree at a temperature of 50° C., but that the bacilli are so debilitated under these conditions that when transferred to a fresh quantity of mash at a more moderate temperature, they produce very little acid and are incapable of further growth in droplet cultures. This weakening is proved to be due rather to the high degree of acidity developed than to the action of the high temperature itself, since cultures at 50° C. in presence of chalk were less seriously affected. Cultures grown at moderate temperatures, e.g., 20° C., produce less acid than those made at 50° C., but they remain in a vigorous condition and can continue to produce acid at temperatures of 20°—30° C., i.e., during the propagation of the yeast; they are also capable of development in droplet cultures at these temperatures.

The acidified mashes on the large scale are pitched with yeast at a temperature of 25° C., and the temperature rises to 26°—29° C. in the course of 24 hours. In most cases a further production of acidity, ranging from 0.9 degree, was observed during this period. The further production of acid was always due to the culture of bacillus (*B. Delbrücki*) alone, and not to infection. The continued acidification was inimical to the yeast, as proved by the more or less rapid dying off of the yeast cells; it was accompanied by decreased attenuation proportional to the increases in acidity. The further production of acid was observed even when the acidified mashes had been "pasteurised" by heating for one hour at 77° C., in spite of the fact that *B. Delbrücki* is immediately killed when exposed, in presence of the acid mash, to a temperature of 72° C. The persistence of *B. Delbrücki* in an active state in the "pasteurised" mashes is attributed to particles of mash on the walls of the tun having escaped the necessary temperature.

The efficiency of the acidification in preventing infection and in suppressing infections produced artificially is extremely satisfactory. A serious infection of mashes showing more than one degree of acidity (0.9 per cent. of lactic acid) is practically impossible, but excessive acidity is liable to injure the yeast.—J. F.

Wines; An Objectionable Method of Fining — R. Bodmer. Analyst, 1905, 30, 261-266.

Attention is called to a fining mixture sold under the name of "Heins Schnell-Klärung." It consists of two separate solutions, one containing 11.117 per cent. of crystallised zinc sulphate, and the other 10.52 per cent. of potassium ferrocyanide. The solutions are supposed to be of exactly equivalent strength, and when mixed in equal volumes to a wine, form a bulky precipitate of ferrocyanide, which settles out and clarifies the wine. The author has found distinct quantities of zinc and ferrocyanide in various samples of Moselle, due to one or other of the above solutions being added in slight excess to the wine, and considers this process of fining to be a most dangerous one.—W. P. S.

Heat; The Proteids of —. 1. *The Proteid Soluble in Alcohol.* T. L. Osborne and J. F. Harris. Z. anal. Chem. 1905, 44, 516-525.

The authors can find no evidence that the proteid dissolved in alcohol from wheat-gluten, consists of more than one substance. The residues obtained on fractionally precipitating the proteid all yielded practically the same amount of glutamic acid, the quantity of the latter being the same in every case. They, therefore, come to the conclusion, that, taking into consideration the composition and the physical and chemical properties of the proteid, by one such substance is present in gluten, and this substance, gliadin, does not consist of two separate proteids, as stated by Kutscher.—W. P. S.

Heat; A Study of Durum —. F. A. Norton. J. Amer. Chem. Soc. 1905, 27, 922-934.

DURUM wheat (*Triticum durum*) is largely grown in the Mediterranean countries and Southern Russia, and is the principal raw material for the manufacture of macaroni. Varieties of this wheat have given very promising results in experimental cultivations in the middle-western States of North America, and are particularly well adapted for semi-arid regions. They give good yields and grade high. Most of the durum wheats are milled only with difficulty and give low yields of flour, but the best Russian varieties are readily milled and compare favourably with yield of flour with the best bread wheats. The high protein content which distinguishes the durum wheat has a tendency to increase still further in the American varieties. These wheats are especially rich in saccharose and dextrin; they have exceptionally large kernels, most translucent, and are characterised by the presence of a yellow colouring matter, which, however, does not detract from the value of the flour, and is considered to be a criterion of quality in macaroni. The gluten content is high but it is somewhat poor in quality, owing to a deficiency of gliadin; this deficiency is, however, compensated in the best wheats by the larger quantity of gluten. The best durum wheats make excellent bread. The colour is slightly yellower than that of ordinary bread, but the flavour is very pleasant. On account of its hardness durum wheat is far more suitable for making the coarse semolina from which macaroni pastes should be made than the more floury bread wheats; it should also be well adapted for "grit" foods. —J. F. B.

ENGLISH PATENT.

To be free from Sugar; Production of —. J. Bouma and S. B. Selhorst. The Hague, Holland. Eng. Pat. 17,818, Aug. 16, 1904.

Cream is separated from the milk by centrifugal

action and washed, the cream is precipitated by acetic acid, filtered off, washed and redissolved in a dilute alkaline solution; thesees in solution are condensed with the separated cream and the necessary salts are added. These salts consist of a soluble calcium salt, such as calcium chloride, sodium chloride, and a soluble phosphate, such as sodium phosphate; the deacidified sweetener is imparted by the addition of "crystalline," the sodium salt of methyl-saccharin. This sugar-free milk can be sterilised at 100° C. without coagulation. —J. F. B.

(B.)—SANITATION; WATER PURIFICATION.

ENGLISH PATENT.

Filtering Material [for Water]; New or Improved — and Method of Producing same. O. Löbber and Dr. W. Weidle, Vienna. Eng. Pat. 6055, March 22, 1905.

One part of chalk, one part of asbestos, two parts of fossil meal and three to five parts of sytate are mixed together, made into a paste with water, compressed in a mould and burnt. The filtering material obtained is of great hardness and toughness, and is not easily broken or cracked either by heat or blows. The proportions can be varied to obtain filters of different degrees of hardness and porosity.—W. H. C.

XIX.—PAPER, PASTEBOARD, Etc.

Japanese Paper-making. Foreign Office Diplomatic and Consular Reports, 1905, No. 635.

The principal paper-making fibres of Japan are obtained from the barks of the paper mulberry (*Broussonetia papy.*) and of the mitsumata (*Edgeworthia papy.*). These materials are consumed in approximately equal quantities, but the mitsumata is gradually replacing the paper mulberry fibre for all purposes where strength is not of the first importance. Other materials, used only in minor quantities, are the barks of "gampi" (*Wikströmia canescens*) and the silk mulberry (*Morus alba*), also straw, wood-pulp, and old papers. The bark is removed by steaming the stems in a primitive manner for 2-3 hours and stripping by hand; the outer bark is then scraped off from the white inner bark by means of a knife. This is not very readily effected in the case of *Broussonetia* and the imperfect portions are separated and used for a coarser grade of paper. The bark is boiled with lime, caustic soda or sodium carbonate, according to the district. The boiled bast is pulped generally by hand-beating with clubs; beating machines are rarely used and yield a paper of inferior strength. A cement or binding material prepared from various plants is added to the pulp; the preparations chiefly used for this purpose are infusions of the roots of *Hibiscus Menirol* or of the resinous bark of *Hydrangea Paniculata*. The mould is made of a net of bamboo laths covered with silk gauze contained in a hinged wooden frame. Owing to the peculiar method of dipping the mould, the fibres of Japanese paper tend to lie all in one direction without felting or interlacing. The thinner qualities of such papers can only be torn parallel to the direction of the fibres; the thicker papers are composed of two layers of fibres arranged in directions at right angles to each other, these papers can hardly be torn at all. The strength of Japanese paper depends on the extreme length and toughness of the fibres; but the strength is not so great as formerly, owing to the increased use of mitsumata and the employment of caustic soda for freeing the bast. The report contains a list of the various classes of paper manufactured in Japan, together with an account of the materials employed, and the nature, uses and properties of the different papers.—J. F. B.

Paper and Pulp Mills; Waste Waters from —. M. L. Griffin. Paper and Pulp, 1905, 10, 492-496.

The author records the following analysis of the spent liquors resulting from the boiling of poplar [soda] wood

pulp: Silica 0.11, iron and aluminium oxides 0.02, calcium oxide 0.05, potassium oxide 0.09, sodium oxide 25.69, carbon dioxide 3.43, acetic acid 9.89 per cent. The organic matter extracted by petroleum spirit boiling below 60° C. was 1.56, by ether 7.14, by absolute alcohol 28.26 and by water 17.02 per cent. The total alkali by titration after incineration of the evaporated liquor was 44.25 per cent. These liquors, of course, are not polluting wastes, but solid and liquid wastes have to be disposed of after their treatment. The waste waters containing fibres and mineral loading from paper mills frequently present great difficulties in filtration. The author finds that if these waters be mixed with a small proportion of new coarse paper stock or sulphite screenings they drain readily, and the whole of the suspended solids can be recovered and used for inferior papers. The carbonaceous residue from the lixiviation of the black ash should be partially dried and burnt under the boilers with forced draft. The calcium carbonate from the causticising tanks should be re-burnt with liquid or gaseous fuel in a continuous rotary kiln; at one mill this waste is mixed with clay and burnt to Portland cement.—J. E. B.

ENGLISH PATENT.

Silk; Manufacture of Artificial—H. E. A. Vittenet. Eng. Pat. 1686, Jan. 27, 1905. V., page 921.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

Opium; Meconic Acid in the Assay of—, and *Certain Alconates*. E. Mallinckrodt, jun., and E. A. Dunlap. J. Amer. Chem. Soc., 1905, 27, 946—964.

In the assay of opium by the U.S.P. 1890 method a yellowish scaly coating, which is evidently not morphine, settles on the bottom of the flask. This scale is now shown to be a double calcium ammonium meconate having the composition $\text{CaNH}_4\text{C}_8\text{H}_7\text{O}_7$ with 2 or 3 mols. of H_2O , the calcium being derived from the opium and the ammonia being added during the assay. If this salt be present the results obtained in the titration of the morphine are too high, since it consumes nearly one-fourth as much acid as morphine itself. The hydroxyl group of meconic acid is replaceable by calcium or barium, and salts in which the meconic acid behaves as a tribasic acid are described. Di- and tri-barium meconates are nearly insoluble in baryta water; the di-calcium and di-barium salts, when prepared in absence of ammonia, are white, not yellow. When barium hydroxide and meconic acid are mixed in proportions corresponding to mono-barium meconate, the di-barium salt is produced and free meconic acid remains in the solution. Meconic acid can be titrated accurately as a di-basic acid by N/10 caustic soda, using blue litmus paper outside the solution as an indicator. The following *résumé* of the literature on meconic acid is appended to the paper:—Serturmer, *Gilbert's Ann.*, 55, 72 and 57, 183; Choulant, *ibid.*, 56, 349; Vogel, *Rep. Pharm.*, 4, 40; Robiquet, *Ann. Chem. Phys.*, 5, 275; Gregory, *Ann. Sparteine [Exhaustive Methylation]. C. Moureu and A. Valeur. *Comptes rend.*, 1905, 141, 261—262.

ONLY one of the two nitrogen atoms of sparteine could be successively methylated by the Hofmann method. The methylsparteine products of the first methylation boil between 171° and 175° C., and have $[\alpha]_D^{20} = -19.67$ and -40° in absolute alcohol. A second methylation of this

product gives a dimethylsparteine boiling at 182°—193° C. at 13.6 mm. If dimethylsparteine is methylated, treated with moist silver oxide, and then heated, there is copious evolution of trimethylamine, and a base, hemisparteine, boiling at 135°—155° C. at 13 mm. is formed. Each of these three bases actively reduces permanganate in acid solution. They are evidently mixtures of isomers and not definite bodies.—E. S.

Sparteine; Constitution of—C. Moureu and A. Valeur. *Comptes rend.*, 1905, 141, 328—330.

THE following facts have been established by the authors and others (see this J., 1903, 961, 1305, 1365, and 1905, 74813):—1. Its formula is $\text{C}_{15}\text{H}_{25}\text{N}_2$. 2. It is a bitertiary diamine. 3. The two nitrogen atoms are equivalent and symmetrical with regard to one another. 4. While the decomposition by heat of methyl- and dimethylsparteinium hydroxides yields methyl and dimethylsparteine tertiary unsaturated bases, that of trimethylsparteinium hydroxide liberates trimethylamine and gives hemisparteine $\text{C}_{15}\text{H}_{25}\text{N}$, a tertiary unsaturated monamine, the nitrogen in which therefore forms part of a bi-cyclic nucleus as

5. Sparteine is not, as Wackernagel and Wolfenstein assert, a pyrrol derivative. Consequently, the above formula probably represents one of the two bi-cyclic nuclei of sparteine; the other is symmetrical, so that the formula may be written $\text{C}_7\text{H}_{12}\text{N} \cdot \text{CH}_2\text{NC}_7\text{H}_{12}$. 6. The stereoisomerism of the two isodimethylates has been established by the authors. A similar case is that of coniine, noticed by Scholtz. In no other alkaloid has this been noticed and coniine having the asymmetric carbon atom *ortho* to the nitrogen, this is probably the position also in sparteine, the formula of which would thus be

This formula is in agreement with other facts besides those given above.—J. T. D.

Aethusa Cynapium; Chemical Examination of—F. B. Power and F. Tutin. Paper read before Internat. Congress of Chem. and Pharm., Liège, July 1905.

PREVIOUS investigations of "fools' parsley" or "lesser hemlock," *Aethusa Cynapium*, Linn., have led widely differing conclusions respecting its constitution and properties, whilst its reputed poisonous action alternately been affirmed and denied. The specimen of the plant used in the authors' experiments were collected during the months of July and August, at a time when fruits were fully developed, but still green. Eleven kilograms of the air-dried herb were exhausted with hot alcohol and the alcoholic extract was distilled with steam. A small quantity (0.015 per cent. of the weight of the fresh plant) of an essential oil of rather unpleasant odour was thus obtained, which was colourless at first, but rapidly acquired a deep brown colour. The aqueous distillate contained a small amount of formic acid. The residue of the distillation flask consisted of a dark coloured aqueous liquid and a quantity (0.8 per cent. of the weight of fresh plant) of a resinous substance. From this resin light petroleum (b. pt. 40°—50° C.) dissolved a portion, which, after boiling with an alcoholic solution of potassium hydroxide, yielded a crystalline hydrocarbon, *peritricontane* $\text{C}_{35}\text{H}_{72}$ (m. pt., 74° C.) and a crystalline alcohol (m. pt., 140°—141° C., $[\alpha]_D^{20} = -35.7^\circ$), which either an isomeride of phytosterol, $\text{C}_{26}\text{H}_{44}\text{O}$, or a low homologue. The alkaline liquid when acidified and distilled, yielded small amounts of formic and butyric acids. The portion of the resin insoluble in petroleum spirit yielded formic, butyric and protocatechuic acids when fused with potassium hydroxide. From

rk coloured aqueous liquid separated from the resin
re isolated: *d-mannitol* (m. pt., 165°–166° C.), a con-
siderable amount of inactive *glucose* and *amorphous*
louring matter, and a very small amount of a *soluble*
kaloid having the peculiar characteristic colour
conine, and which, like the latter, yielded butyric acid
oxidation. The amount of hydrochloride of the
kaloid obtained corresponded to 0.0003 per cent. of the
weight of the fresh plant, which, if the base be regarded
conine, is equivalent to 0.00023 per cent. of the latter
the plant. The alkaloid was found to resemble conine
its physiological action. The authors conclude that,
view of the fact that the specimens of *Aethusa Cynapium*
analyzed by them contained a small amount of a volatile
kaloid resembling conine in physical and chemical
characters and also in physiological action, it cannot be
considered improbable that, under favourable conditions of
growth, the proportion of alkaloid may be increased to
such an extent as to impart to the plant the poisonous
properties ascribed to it.—A. S.

anogenetic Glucoside of the Elder [*Sambucus nigra*].
L. Guignard and J. Houdas. Comptes rend., 1905,
141, 236–238.

GLUCOSIDE, together with a hydrolytic enzyme, is
found in the leaves and green cortex of the twigs of the
common elder. The enzyme only is found in the root.
A quantity of the leaves was macerated with water,
which was then distilled. Benzaldehyde was found in
the distillate, showing the glucoside to be amygdalin.
—F. S.

gentianin. G. Tanret. Comptes rend., 1905, 141, 263–264.

gentianin is the sparingly soluble glucoside, associated to
the extent of about 1 per cent. with gentiopierin. It
crystallizes from dilute alcohol in slightly yellow micro-
scopic needles. It melts at 274°C. with decomposition;
molecular formula $C_{25}H_{28}O_{14}$. On hydrolysis with dilute sulphuric
acid, it yields dextrose, xylose ($C_5H_{10}O_5$), and gentianin
($H_{10}O_5$). Gentianin recrystallizes from alcohol in
pale-yellow needles, insoluble in water. It is isomeric
with gentisin. It differs from gentisin in melting at
170°C., and in giving a yellow coloration when dissolved
in cold nitric acid.—F. S.

ethyl Dialkyl Barbituric Acids; Manufacture of —.
Chem. Fabr. von Heyden Akt.-Ges., Radebeul, Ger-
many. Eng. Pat. 10,201, May 15, 1905. Under Int.
Conv., July 15, 1904.

PROCESS is claimed for making guanyl dialkyl barbituric
acid by heating dicyandiamidine and dialkyl malonic acid
dialkyl esters with sodium alcoholate or with condensing
agents of analogous action. (See U.S. Pat. 787,360, this
1905, 559.)—F. S.

mercury Cholate Salts of Mercury; Impts. relating
to —. J. Wetter, London. From J. D. Riedel,
Akt.-Ges., Berlin. Eng. Pat. 11,180, May 29, 1905.

mercury salts of cholic acid are obtained by treating
a dilute solution of a salt of cholic acid with a neutral
mercury salt solution, preferably the mercury salt of
folic or another organic acid. Mercurous cholate,
 $H_{39}O_5Hg$ is a yellowish-white light powder almost
insoluble in water, and is decomposed by the addition of
alcohol. Mercuric cholate, $(C_{24}H_{39}O_5)_2Hg$, is a yellowish-
white powder, very sparingly soluble in pure water, more

easily soluble in water containing alkali (especially sodium
or potassium chloride) in solution, and soluble in alcohol
with decomposition. F. S.

XXII.—EXPLOSIVES, MATCHES, Etc.

Explosives Factories and Testing Stations; Report on
Visits to Certain — in Belgium, Germany and Holland.
By Captain M. B. Lloyd and Captain A. P. H. Des-
borough, H.M. Inspectors of Explosives.

Explosives Factories. At the Eserden Factory, Belgium,
the danger buildings are erected on a somewhat novel
plan. They are circular in ground plan and lighted
entirely from the roof by means of a patent glass having
wire-netting in it, and which it is claimed will not let a
splinter fall, even if it is very badly cracked. The mounds
are then erected right up against the walls of the buildings,
exceeding them in height by several metres. For
this method of construction it is claimed that the force
exerted by an explosion will expend itself in a vertical
direction.

At the Haltern factory, Germany, every door on the
nitroglycerin hill is provided with a leather pad, so hung
by a short strap that it prevents the door from banging,
thus avoiding the sudden impact otherwise suddenly
given on a surface which might possibly have a film
of nitroglycerin on it. In the nitrating and washing
houses, cylinders of compressed carbon dioxide are con-
nected with the air pipes so that in the event of a failure
of the air supply the stirring can be continued with this
gas if necessary.

At the Troisdorf factory, Germany, considerable quan-
tities of trinitrotoluene are now being used in the manu-
facture of detonators. This substance is much safer
to handle than fulminate of mercury, but as all such
detonators require a priming of fulminate, as soon as this
is introduced the risk becomes the same as with the older
pattern. In the smokeless powder factory most of the
operations are carried on with wet explosive, it being
forbidden in Germany to use the dry process for the manu-
facture of smokeless powders.

At the Schlebusch factory, Germany, an arrangement
has been installed, in the nitrating and separating houses,
whereby in the event of an alarm, all the cocks to the
drowning tanks can be turned on by means of a piston
driven by compressed air, which can be operated by turn-
ing on a small air valve outside the mound.

Testing Stations.—At most of the testing stations
visited, the gas gallery was constructed of wood, being
elliptical in section with the major axis vertical, the
diameters varying from 1.65 to 1.85 metres for the major
axis and from 1.35 to 1.45 metres for the minor
axis. The capacity of the explosion chamber was usually
10 cb. m. At the Haltern testing station, however,
the gallery was constructed of boiler plate, and the ex-
plosion chamber had a capacity of only 4 cb. m.
At this particular station it is said to have been proved
that an iron gallery is more sensitive than one made of
wood, and that the greater the length of the bore of the
cannon the greater the liability to ignition. Pit gas is
most generally employed as the inflammable constituent,
but in some cases coal gas is employed, and, in one case,
benzene vapour. The results, obtained with these latter,
in comparison with other stations using natural gas, are
held to be very re-assuring as to the value of experiments
made with coal gas or other substitutes. In nearly all
cases coal dust, freshly ground, is also employed in the
explosion chamber. It was generally held that its presence
did not increase the sensitiveness to explosion, but merely
added to the violence and visibility of the ignition. The
bores of the firing cannons varied from 30 cm. to 70 cm.
in length and from 4 cm. to 6 cm. in calibre. At the
Haltern station, previously mentioned, an exceptional
bore of 150 cm. is also employed. At the testing station
of the Caronit Akt.-Ges. at Schlebusch, in addition to
the usual wooden gallery, a smaller gallery of the same
dimensions as the one in use at Woolwich has been erected.
It has been found that the relatively smaller diameter of

the explosion chamber in the Woolwich pattern gallery renders it far more sensitive and thus the use of stemming becomes a necessity. At Woolwich it has been found that extremely small charges of any explosive, when unstemmed, suffice to fire the gas, whereas on the Continent large charges fail to do so. The nature of the gas has apparently little influence and the reason of the difference is considered to lie in the dimensions of the explosion chamber. The important factor is undoubtedly the diameter, and sensitiveness would appear to vary, roughly, inversely as the sectional area of the gallery.

In Belgium the function of the Government testing station is similar to that at Woolwich. The most important difference lies in the fact that a definite maximum charge is prescribed for each explosive. This *charge limite* is determined by actual experiment at the testing station, and may be defined as the maximum charge which will not ignite the inflammable mixture when fired in the testing gallery.

In Germany only "safety explosives" may be used in dangerous mines, the onus of proof as to what constitutes a "safety explosive" resting with the mine owners. The methods adopted for mixing the gas and air in most of the installations are considered to be crude. A No. 8 detonator is always used, and little attention is paid to the nature of the wrapper, whereas at Woolwich ample proof has been obtained that this is a matter of practical importance. Only limited attention is paid to the regularity of detonation of individual charges, and air spacing of the charge is considered as being quite unimportant. G. W. McD.

Explosives; Researches on —. Sir A. Noble, Roy. Soc. Proc., 1905, 76, A, 381—386. (See also this J. 1895, 185.)

THE object of the research was to ascertain the differences in the transformations which modern explosives suffer when fired under gradually increasing, but considerable, differences of pressure. Comparative results are given for the following three explosives (1) Cordite Mark I. (2) Modified cordite known as MD. (3) Tubular nitrocellulose known as R.R. Rottweil. Eight experiments were carried out in each case, the density of charge exploded varying from 0.05 to 0.50. In the following table the lowest, middle and highest densities are selected from those given in the original tables. —

	Cordite Mark I.				Cordite MD.			Nitrocellulose.		
Density of charge exploded	—	0.05	0.25	0.50	0.05	0.25	0.45	0.05	0.222	0.4
Volume of permanent gas per gram	—	678.0	691.9	623.6	781.8	745.5	676.3	814.7	759.2	680.9
Volume of total gas per gram	—	877.8	871.3	798.8	955.4	888.6	810.6	993.1	922.3	816.3
Percentage volume of permanent gases	CO ₂	27.15	31.75	41.95	18.15	26.75	36.60	17.90	25.10	35.0
	CO	34.35	28.00	19.10	42.60	33.65	24.80	43.45	36.55	27.8

Comparative potential energy	—	0.9825	0.9689	1.0000	0.8401	0.8215	0.8842	0.7389	0.7438	0.7686

The transformation on firing appears, in all three explosives to follow the same general laws. With increase of pressure there is, at first a slight increase, afterwards a steady decrease in the volume of permanent gases produced, also a large increase in the volume of carbon dioxide and a

large decrease in the volume of carbon monoxide. The volume of hydrogen decreases with increasing pressure while that of methane rises rapidly. The temperatures of explosion, which can only be taken as provisional, have been obtained by dividing the units of heat (water gaseous) by the specific heats. From other considerations the author is inclined to believe that these temperatures are not very far removed from the truth. The wide differences in the transformation of the three explosives show that any attempt to describe by a chemical equation the nature of the metamorphosis which an explosive may be considered to undergo would only be calculated to convey an erroneous impression regarding the definite nature of the chemical results and their uniformity under different conditions. Experiments made on erosion, with the three explosives referred to, show that the amount of absolute erosion is governed practically entirely by the heat developed by the explosion. Under pressures varying from 5 tons to 32 tons per sq. in., erosion is practically entirely independent of the pressure both for cordite and nitrocellulose. G. W. McD.

Ammonium Oxalate; Formula and Stability of — [Use in Explosives]. P. V. Dupré. Analyst, 1905, 30, 266—273.

PURE ammonium oxalate prepared by recrystallisation at the boiling temperature, at ordinary temperatures, and at a temperature near the freezing point, furnished crystals of which had a composition agreeing with the formula (NH₄)₂C₂O₄ · 1½H₂O. In no case under any of the conditions named, were crystals obtained with more or less than 1 mol. of water.

In perfectly dry air ammonium oxalate loses water even at 12° C., although very slowly, whilst at 40° C., the evaporation is fairly rapid, being complete in two days. Under reduced pressure (1 mm.) the percentage loss was the same as before, but much more rapid, the salt losing its water in three days at a temperature of 67° C. The rate of decomposition is very nearly constant for any given temperature, and approximately doubles for every rise of 10° C.

The presence of ammonium oxalate in an explosive might be expected to affect the heat test, as minute traces of ammonia are set free when the salt is heated. Experiments show, that, although in the case of an explosive

giving a high heat test, the effect is very noticeable, it is of no practical importance with samples giving low tests. It is shown that the vapour pressure curve of ammonium oxalate does not reach that of water even at a temperature of 95° C., nor does it even reach the curve representing

e vapour pressure of moisture in air saturated to the extent of 70 per cent., so that the salt will be stable at all temperatures up to 95° C., provided that the air is not less than half saturated with moisture.—W. P. S.

nitric Acid; Manufacture of —, F. Winteler. VII., page 924.

UNITED STATES PATENTS.

Explosive Compound. F. G. Dokkenwadel, Coshockton, Ohio. Assignor to H. M. Grant, New York. U.S. Pat. 795,825, Aug. 1, 1905.

An explosive is composed of paper pulp, mixed with an excess by weight of sodium nitrate and potassium nitrate, sulphur, to the amount of about one-third the weight of pulp employed, is added and also glucose and glue, the whole being incorporated and formed into grains.
—G. W. McD.

Explosives; Process for Making —, J. C. Smith, Lovington, Ill. U.S. Pat. 795,940, Aug. 1, 1905.

ANIM is made for the manufacture of a granular explosive composition, by dissolving a mixture of sugar and saltpetre in water, heating the solution to the boiling point; adding potassium chlorate and then powdered coal to form a paste, which is afterwards dried and pulverized.
—G. W. McD.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS, ETC.

Melting-points of Fats; Apparatus for Determining —, A. Ubbelohde. Z. angew. Chem., 1905, 18, 1220—1225.

Ubbelohde's method of immersing the bulb of a thermometer in the melted fat, allowing the adherent fat to cool, and then immersing the coated thermometer in an empty test-tube, slowly heating in a water-bath, taking as melting-point the temperature at which the first drop falls, is subject to many inaccuracies, some of which are removed by Finkener's method, who substitutes for the thermometer glass rods, specifies dimensions and time of immersion in the melted fat, and places the rods and a thermometer symmetrically in a test-tube of given dimensions for heating. Apart from the fact, however, that in the dipping method, the rod is likely, in a non-homogeneous fat, to become coated with an unduly large proportion of the higher-melting constituents, the author states that the temperature indicated by Finkener's method varies with the amount of substance adhering to the rod. If this be very small, the outer layer becomes mobile before a drop falls, and this drop is then small and the temperature high; while if it be very large, a large drop soon collects from the large surface, and falls at a lower temperature in consequence of its weight. In either case, however, the ratio of the weight of the drop to that of the total amount of substance is large, and in any series of experiments in which the weight of substance is usually increased from the one extreme or gradually diminished from the other, it is found that there is one ratio for which the above-mentioned ratio is a minimum. The actual value of this ratio at this point depends on the dimensions (diameter of rod and depth of immersion) of the apparatus used; but the temperature indicated as the melting-point when this minimum ratio is attained, is not thus dependent, but is constant, whatever the dimensions of the apparatus may be, and is regarded by the author as the true melting-point of the fat. The determination of the melting-point in this way, however, is obviously a very long and laborious process; but the author finds that it can be determined at one operation by the use of the apparatus figured:—

FIG. 1.

FIG. 2.

On the thermometer *a* fits tightly the metallic casing *c*, whereby there is a small opening at *c*. The lower portion of this casing carries the little glass vessel *d*, which is 10 mm. long, 7 mm. in internal diameter, and has an opening at the bottom 3 mm. wide. The vessel is ground flat at the ends, and the thermometer bulb must be truly central in it. The upper edge of *d* is 2 mm. above the top of the bulb; the little set screw *e* allows of adjusting this. The little glass vessel is taken out and filled (in the case of a moderately soft fat) by pressing the substance into it, cutting away the excess top and bottom; then it is replaced. With a hard fat, to avoid breakage of the thermometer, *c* is placed narrow end downward on a flat glass plate, filled exactly with the melted fat from the little pipette, and when the fat has solidified but is not yet set hard, the rest of the apparatus is pushed down into place from above. The apparatus is then fastened by a cork in a 4 cm. wide test-tube, and heated as in Finkener's method, the temperature of the bath being raised at the rate of 1° C. per minute. The temperature indicated when the curved surface of the fat issuing from the hole is just visible, is taken as that of the beginning of flow, and the temperature when the first drop falls is the melting-point. Clearly this will not be absolutely accurate, for

there will always be a gradient of temperature from the outer layer of fat down to the thermometer; the author finds that the correction for this, with the apparatus and rate of heating prescribed, is for all ordinary fats and waxes + 0.5° C. As it is practically a constant, it may be neglected if the melting-point be defined as the temperature indicated by the instrument. Successive determinations on different instruments, with not too great variations in

dimensions, should not differ by more than 0.2° C.

—J. T. D.

INORGANIC—QUALITATIVE.

Nickel; Sensitive Reagent for —, L. Tschugaeff. Ber., 1905, 38, 2520—2522.

α -DIMETHYLGLYOXIME, $\text{CH}_3\text{C}(\text{NOH})\text{C}(\text{NOH})\text{CH}_3$, is a very sensitive reagent for nickel in solution, and gives a scarlet precipitate, or, with traces of nickel, a yellowish solution from which the red precipitate separates on cooling. The best method of applying this reagent is to remove excess of acid from the solution to be tested by adding excess of ammonia or sodium acetate, and then to add the powdered dimethylglyoxime, and to boil for a short time. Distinct indications are obtained with solutions containing only one part of nickel per 400,000 of water. The reaction is not disturbed by the presence of ten times as much cobalt as nickel, but when the proportion of cobalt is much greater than that of nickel, it is best to add a very large excess of ammonia to the liquid and to shake repeatedly, excess of the diosime being then added and the solution boiled for a short time. In testing

by this method for nickel in such products as commercial cobalt salts, the reaction is manifested by the appearance of a scarlet scum rising up the walls of the test-tube, but it is generally necessary to filter or siphon off the cooling liquid and wash the residue with water; in presence of nickel this residue is red, but if nickel is absent, it is quite colourless. In this way one part of nickel can be detected when admixed with 5000 parts of cobalt.

T. H. P.

INORGANIC—QUANTITATIVE.

Sodium: Detection and Determination of —, in presence of Lithium Compounds, by Hydrofluosilicic Acid. C. Reichenard. *Chem.-Zeit.*, 1905, 29, 861–862.

HYDROFLUOSILICIC acid is proposed as a reagent for the detection and determination of sodium in the presence of lithium. The author finds that lithium compounds even in concentrated solution produce no turbidity with this acid and separate no precipitate even after 24 hours. Sodium salts on the other hand, are precipitated from solutions containing only 0.25 per cent. of sodium. Potassium salts, however, are also precipitated, and when this metal is present as well as lithium and sodium, indirect analysis, such as the conversion of the silicofluorides to sulphates, may be resorted to. F. S. N.

Antimony: Determination of — as Trisulphide, and the Separation of Antimony from Tin. G. Vortmann and A. Metz. *Z. anal. Chem.*, 1905, 44, 525–535.

The solution containing the antimony is acidified with at least 24 c.c. of concentrated hydrochloric acid for each 100 c.c. of the neutral solution, and heated to boiling. Hydrogen sulphide is then passed through the hot solution until the yellow antimony trisulphide which is precipitated changes to a red colour and finally black. Towards the end, the flask, in which the precipitation is carried out, is gently shaken. The black crystalline precipitate is collected on a filter, washed with water and alcohol, and dried. Before weighing the precipitate, the small quantity of free sulphur contained in it is removed by means of carbon bisulphide. Instead of weighing the precipitate directly as antimony trisulphide, it may be mixed in a crucible with iron sesquioxide and ferric nitrate— $\text{Fe}(\text{NO}_3)_3$ —and ignited, when antimony pentoxide is obtained. The heat should be applied cautiously at first, but at the end, a blast flame is used. The quantity of iron oxide and nitrate added is weighed out and the iron oxide it yields after ignition determined by a preliminary experiment.

For the separation of antimony from tin the mixed sulphides of these two metals are dissolved in a little hydrochloric acid (1:1) and the solution is neutralised with solid sodium carbonate or hydroxide, using a drop of phenolphthalein as indicator. After diluting to 60 c.c. with water, 60 c.c. of phosphoric acid (sp. gr. 1.3) and 24 c.c. of concentrated hydrochloric acid are added, the mixture is boiled and precipitated with hydrogen sulphide as described above. An equal volume of water is then added, the mixture again boiled and treated with a little more hydrogen sulphide. After filtering off the antimony trisulphide, the tin may be precipitated in the filtrate, by neutralising the greater part of the acid, diluting and passing hydrogen sulphide into the solution. The above method is stated to completely separate the two metals from each other.—W. P. S.

Cement: Detection and Determination of Free Blast-Furnace Slag in —. M. Gary. *Mitt. Königl. Materialprüfungsamt zu Gross-Lichterfelde West.*, 1905, 23, 1–21.

THE process recommended, is first to determine the presence of sulphide sulphur in the cement to be examined; as sulphides are absent in well sintered cement clinker, their presence indicates admixture of slag. The object then is to obtain on the one hand pure slag, and, on the other, pure clinker meal, and from analytical determination of some constituent in the slag to calculate the amount of free slag in the cement as a whole. By removing the finest dust, it is comparatively easy to

separate by suitable liquids, such as a mixture of methyle iodide and oil of turpentine, the slag from the cement. About 500 grms. of the cement are treated on a sieve containing 10,000 meshes to 1 sq. cm., when generally about 150 grms. are left on the sieve; this portion freed from iron by a magnet, and washed with alcohol and ether, and dried. Of this "grit" 60 grms. are treated in a separating apparatus with a mixture of methyle iodide and oil of turpentine of a sp. gr. of 3.0, and the separation repeated if necessary on the light and heavy portions obtained after filtering. The portions are then examined for loss on ignition, silica, lime, insoluble matter, and sulphide sulphur. The sulphuric acid is determined as barium sulphate in the usual way in 4 grms. of the substance; another 4 grms. are oxidised with bromine water and the total sulphuric acid (including the oxidised sulphur) determined; the difference between the two amounts gives the sulphur present as sulphide. Calculation is as follows:—

Slag, free from carbon dioxide, water, and matter insoluble in hydrochloric acid—

Residue contains a per cent. sulphide sulphur.

Clinker contains b per cent. sulphide sulphur.

Mixed cement contains c per cent. sulphide sulphur.

Then the amount x of slag in the mixture is given by the equation:—

$$x = 100 \frac{c-b}{a-b}.$$

For if y denotes the amount of clinker particles in mixed cement, then:—

$$\begin{aligned} y &= 100 - x \\ \text{Hence, } x + y &= 100 \\ \frac{x.a}{100} + \frac{y.b}{100} &= c \\ \frac{x.a}{100} + \frac{(100-x)b}{100} &= c \\ \frac{x.a + 100.b - x.b}{100} &= c \\ x.a - x.b + 100b &= 100c \\ x(a-b) &= 100c - 100b \\ x &= 100 \frac{c-b}{a-b}. \end{aligned}$$

(See also this J., 1900, 903; 1901, 1143; 1902, 72; and 1903, 822, 1087.)—W. C. H.

Cyanide Solutions; Assaying —. A. M. Henderson. *Inst. of Mining and Met.*, May 18, 1905. [Advanced Proof.]

THE solutions to be assayed are electrolysed for a period of four hours, the gold being precipitated on a cathode of lead-foil, the anode consisting of a wrought-iron plate. The formation of Prussian blue on the anode is prevented by the addition of an excess of ammonia; the necessary circulation of the solution is caused by the liberated gas bubbles and by the peculiar shape of the cathode.

The precipitation of gold is said to be very complete in solutions containing 10 to 15 dwt. of gold per ton, or 0.03 to 0.25 per cent. of cyanide, the value can be reduced to below 3 grs. in four hours with a suitable current density. Ten assay tons (292 c.c.) of solution are placed in a tall beaker, and 12 to 15 c.c. of strong ammonia added.

The lead cathode consists of a cylinder of lead (2½ in. high and 1 in. in diameter), with three V-shaped notches cut in the lower rim, a lead strip being attached at the top with which to make connection. The lead-foil cylinder should be covered to a depth of about ½ in. A 6 in. nail is used as an anode. The disengaged gas bubbles cause an upward current in the solution inside the cylinder, down round the outside, and through the V-notches in the bottom.

It is usual to make from 14 to 20 assays at one time, all joined in series between the terminals of 110-volt lighting mains. With 20 assays in series, no extra resistance is necessary; but with a lesser number than 14, incandescent lamps are inserted.

The current used is from 0.06 to 1.2 ampère; the fewer the solution, the higher the current density that can be safely used. The gold separates as a bright yellow

leposit, and, when precipitation is complete, the cathode is washed in water, dried, rolled up and scorified with the addition of some test-lead and cupelled.—A. S.

Electrolysis [*Electrolytic Analysis*]; *Methods* —. N. Puschin and R. Trechevski. J. russ. phys.-chem. Ges., 1905, 37, 392—417. Chem. Centr., 1905, 2, 374—375.

In the carrying out of electrolytic methods of analysis, the authors point out the importance of arranging in advance, not only the desired E.M.F., but also the necessary assistance. In the more recent descriptions of electrolytic processes, the current strength or current density is usually given in addition to the E.M.F., but according to

Ohm's law for conductors of the second class: $i = \frac{E}{R + r}$, where

i is the true current strength, E is the E.M.F., r is the resistance of the electrolyte, and R is the resistance of the circuit. The authors recommend that in descriptions of electrolytic methods of analysis there should be given besides E.M.F. and current density, also the opposing E.M.F.; besides E.M.F., the "s-g electrolytic constant" (K). The significance of this constant may be indicated as follows:—If E , i , j , η , q , and ω represent respectively the E.M.F., current strength, current density, opposing E.M.F., area of cathode surface, and resistance of the electrolyte, then since $i = \frac{E - \eta}{\omega}$, and $i = j \cdot q$, $\frac{E - \eta}{\omega} = j \cdot q$, $K = \frac{E - \eta}{j \cdot q \cdot \omega}$.

If E and K be known, the resistance may be easily calculated by the formula $\omega = \frac{1}{j \cdot q \cdot K}$.

As the result of numerous experiments, the authors state that, in general, the formation of precipitates during electrolysis has no injurious effect. Reference is also made to the use of rotating electrodes, and it is stated that equally satisfactory results are attained by vigorous agitation of the electrolyte by means of a mechanical stirrer.—A. S.

ORGANIC—QUANTITATIVE.

Sodium Peroxide; *Use of* — in *Organic Analysis*. H. H. Pringsheim and J. A. Gibson. Ber., 1905, 38, 2459—2461.

The authors have shortened the tedious portion of the halogen determination by means of sodium peroxide (this J., 1904, 76 and 504) devised by Pringsheim, namely, the titration, by substituting in the reducing process, sodium sulphite and sulphuric acid for aqueous sulphurous acid. The bulk of liquid to be dealt with is thus very much reduced, and the addition of 3 c.c. of strong nitric acid, before precipitating the halogens, prevents any co-precipitation of silver sulphate (*loc.cit.*). Even where the use of aqueous sulphurous acid is preferred, however, the titration can be very rapidly carried out with a Gooch crucible and the use of the pump. Experience has proved not only that this method is far more convenient than Arius' method, but that determinations can be made with ease on substances (Kanfner's β -iodoanthraquinone, for example) which are only with great difficulty decomposed by nitric acid in sealed tubes. Results are noted of analyses of β -iodoanthraquinone, of the trichloro- and tribromo-derivatives of phenol and of resorcinol and of aqueous-compounds of each of these with paranitroso-methylaniline, and of tetrachlorocatechol. These analyses were all made by Gibson with previous experience of the method, and the results are in every case closely concordant with theory.—J. T. D.

Coal; *Examination of* —. O. Pfeiffer. J. Gasbeleucht., 1905, 48, 713—715.

For the control of consignments of coal, determinations of the sulphur and ash and of the yield of coke by the crucible method usually suffice.

Coke.—The following method is stated to give more concordant results than the older process of Muck. A platinum crucible, having a height of 35 mm. and a diameter at the bottom of not less than 22 mm., is used,

and is supported on a triangle of thin platinum wire above a Bunsen burner giving a flame 15 cm. high, the distance between the crucible and the top of the burner being 2 cm. The crucible has an overlapping flange, a neck of 2 mm. diameter. One gram. of the finely powdered coal is weighed out and is ignited in the crucible, till the ring of soot which is formed round the hole in the lid disappears.

Ash.—The crucible containing the coke, after weighing, is placed nearly horizontally on the triangle, and heated with the full flame of the burner, so disposed that the tip of the inner cone of the flame just touches the edge of the crucible. The incineration is stated to be complete in one hour.

Sulphur.—It is only necessary to determine the volatile sulphur in the coal, and Eschka's method is therefore inapplicable. Graef's modification of Hempel's method (Z. angew. Chem., 1904, 516) gives good results, but the author has simplified it by determining the sulphuric acid formed by combustion of the sulphur, volumetrically instead of gravimetrically, and by substituting an asbestos holder for the coal for one of platinum. This asbestos cup is made by shaping a wetted disc of sheet asbestos, drying, and igniting; it is supported by a piece of thick copper wire, the other end of which is connected to the rubber stopper used for closing the flask in which the combustion is effected. One gram. of the coarsely-powdered coal is weighed into the asbestos cup and the latter introduced into the flask, which has a capacity of about 5 l. litres. The flask is filled with oxygen, rinsed out with distilled water which has been made neutral to methyl orange by means of sulphuric acid, and then 20 c.c. of N/10 alkali hydroxide solution introduced. The water and alkali are introduced through a hole in the stopper, which is subsequently closed by a glass rod. The coal is then ignited by a piece of glowing tinder (free from sulphur and chlorine). After half an hour, the walls of the flask are rinsed with distilled water and the excess of alkali is titrated with N/10 acid. From the percentage of sulphur found, 0.018 must be deducted as a correction for the nitric and nitrous acids produced during the combustion, and allowance must also be made for the hydrochloric acid also formed, this being determined by titration with N/10 silver nitrate solution. By this method a sulphur determination can be completed in one hour, and the results are in agreement with those obtained gravimetrically by Graef's method.—A. S.

Glycerol; *Comparison of Methods of Determining* — in *Distilled Glycerins, Crude Glycerin and Soap Leys*. F. Schulze. Z. landw. Versuchsw. in Oesterr., 1905, 8, 155. Chem.-Zeit., 1905, 29, Rep. 218.

From the results of comparative determinations the author concludes that no reliance can be placed upon the permanganate method, even for the determination of glycerol in oils and fats. The acetic method is usually satisfactory, but does not give good results with soap leys containing 20 to 25 per cent. of glycerol. Zeisel and Fanto's iodide method (this J., 1902, 922) is satisfactory, but is too costly and tedious for commercial work. The bichromate method as modified by Richardson and Jaffé (this J., 1898, 330) is rapid and gives good results, but the volumetric method yields figures somewhat too low, and in the case of concentrated glycerin the error may, under certain conditions, be considerable. For scientific work the iodide method and Richardson and Jaffé's modification are regarded by the author as the most satisfactory.

—C. A. M.

Ethyl and Methyl Alcohols; *Detection and Determination of* — in *Mixtures, by the Immersion Refractometer*. A. E. Leach and H. C. Lythgoe. J. Amer. Chem. Soc., 1905, 27, 964—972.

THE refraction reading of methyl alcohol in the Zeiss immersion refractometer differs so widely from that of ethyl alcohol that it affords a very convenient means for the detection and determination of highly purified wood-spirit in pharmaceutical preparations. Whilst the specific gravities of these alcohols and their aqueous solutions at equal strengths are nearly identical, ethyl alcohol of 91 per cent. strength gives a refractometer reading of 98.3° at 20° C., whereas methyl alcohol of the same

strength reads only 14.9. The difference between the refractometer readings of the two alcohols varies according to the alcoholic strength, as illustrated in curves, the widest differences being observed at strengths above 50 per cent.

In testing for methyl alcohol, the liquid is distilled, and if the refractometer reading indicates a percentage of alcohol agreeing with that obtained from the specific gravity, the absence of methyl alcohol can be inferred, but if the refraction is too low, and if other refracting substances are absent, the percentage of methyl alcohol can be deduced with a fair degree of accuracy by reference to tables which have been constructed by the authors. Care should be taken to eliminate any volatile oils from the liquid before distillation, but mere traces of oils do not cause any serious error. Acetone if present impairs the accuracy of the results, but the purified methyl alcohol which would be used as an adulterant is almost free from acetone.—J. F. B.

Strychnine and Brucine: Separation of — D. L. Howard. *Analyst*, 1905, 30, 261–263.

In an investigation of Keller's method, the author found that, at a sufficiently low temperature, brucine can be completely destroyed in the presence of strychnine by the action of nitric acid, without any loss of strychnine taking place. The low results stated to be given by Keller's method are simply due to the use of chloroform and ether as solvents. By properly extracting the acid-treated alkaloids, the whole of the strychnine may be recovered.—W. P. S.

Meconic Acid in the Assay of Opium, and Certain Meconates. E. Mallinckrodt, jun. and E. A. Dunlap. *XX.*, page 944.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Sodium Iodide: Crystallisation of — from Alcohols. M. Loeb. *J. Amer. Chem. Soc.*, 1905, 27, 1019–1020.

According to the author the crystals obtained from alcoholic solutions of sodium iodide contain alcohol of crystallisation, whilst those from solutions of potassium iodide do not. The following compounds were prepared with sodium iodide:—From methyl alcohol solution, $\text{NaI} \cdot 3\text{CH}_3\text{OH}$ in large plate-shaped crystals or white felted needles; from ethyl alcohol solution, $\text{NaI} \cdot \text{C}_2\text{H}_5\text{OH}$; and from normal propyl alcohol, $5\text{NaI} \cdot 3\text{C}_3\text{H}_7\text{OH}$.—A. S.

Sulphur; Amorphous —. III. The Nature of Amorphous Sulphur and Contributions to the Study of the Influence of Foreign Bodies on the Behaviour of Supercooled Melted Sulphur. A. Smith and W. B. Holmes. *J. Amer. Chem. Soc.*, 1905, 27, 979–1013. (See this J., 1903, 322; 1905, 861.)

The present paper comprises a detailed account of numerous experiments on the different modifications of sulphur, and a discussion of the results obtained. In the hardening of plastic sulphur partial reversion of the amorphous (insoluble) sulphur to soluble sulphur takes place, and it is thus impossible, under these conditions, to obtain in quasi-solid form the whole of the amorphous sulphur present in the plastic material. Sulphur obtained by precipitation in the presence of concentrated acid, however, yields 100 per cent. of insoluble sulphur, and the smaller yields obtained from melted sulphur appear to be due to the impossibility of realising the requisite condition of very fine subdivision. The presence of various substances in melted sulphur causes an increase in the yield of amorphous sulphur obtainable therefrom. Iodine appears to be the most efficient in this respect. Sulphur to which iodine has been added in the proportion of two parts per 100 of sulphur, gives when heated and chilled, yields of insoluble sulphur ranging from 4 per cent. after chilling from 110°C . to 62.7 per cent. after chilling from 448°C . Determinations of the boiling point at ordinary and at reduced pressures, of specific gravity and of solubility,

showed that sulphur which will give the insoluble form when chilled is identical in constitution with that which will not, and prove that the insoluble form is present in all specimens of melted sulphur in proportions depending on the temperature alone, whether by treatment with ammonia or otherwise, the sulphur has lost the capacity to give insoluble sulphur by chilling or not. The authors conclude that amorphous sulphur is supercooled S_{μ} —the form stable above 160°C . In the case of pure sulphur freed from sulphur dioxide by recrystallisation, or by treatment with carbon dioxide above 310°C ., or by treatment of melted sulphur with ammonia or hydrogen sulphide, the S_{μ} reverts so rapidly to the soluble form that it cannot be supercooled. When, however, traces of sulphur dioxide, iodine and other substances are present S_{μ} is more or less completely supercooled and gives hardened amorphous sulphur, in which condition the reversion to soluble sulphur proceeds with extreme slowness, the proportion of insoluble sulphur showing little reduction, even after keeping for months.

In conclusion the authors point out the similarity between the phenomena observed and those encountered in the study of the chilling of iron and steel. For example pure iron (α -ferrite) is transformed into β -ferrite at 755°C and the latter into γ -ferrite above 890°C ., this last modification being non-magnetic. These temperatures of transition points analogous to 95.46° (change of rhomb sulphur into the monoclinic form) and 160°C . (change of melted soluble sulphur S_{λ} into melted amorphous sulphur S_{μ}) for sulphur. On chilling, γ -ferrite rapidly reverts to α -ferrite and recovers magnetic qualities, but the presence of 12 per cent. of manganese so reduces the ease with which this reversion takes place, that when the alloy is chilled the product contains only supercooled γ -ferrite and is wholly non-magnetic. Also, Charpy and Grenet (this J., 1902, 616) have shown that silicon favours the separation of graphite in cast iron, facilitating the initial appearance of the carbon phase and causing the separation to proceed more rapidly after it has been initiated, whilst at the same time not affecting the amount finally deposited when the system has reached a condition of equilibrium.—A. S.

Ozone: Production of — by Ultraviolet Light.

Fischer and F. Braehmer. *Ber.*, 1905, 38, 2633–2635

ONE of the authors has devised a form of mercury-arc-lamp containing a double-walled quartz vessel through t annulus of which a gas can be passed, and thus exposed to the radiation of the arc. The lamp can be immersed in water and its outer glass casing thus kept cool, and a stream of water (or other cooling liquid) can be passed through the interior of the quartz tube, cooling one coat of the annulus, and hence, as the annular space is on about a mm. across, cooling the contained gas very considerably. Through this apparatus pure oxygen, generated electrolytically from dilute sulphuric acid, was passed and exposed to the radiation from the arc. The total quantity of ozone formed during an experiment (15 minutes) was determined, and hence, from a knowledge of the quantity of gas that had passed, the percentage by weight in the ozonised gas. The results showed that without any cooling, when the temperature rose to 270°C ., no ozone was formed; when cooling water was used, increase of its speed at 15°C ., or lower of its temperature, increased the yield of ozone. Under constant conditions of cooling-water, increase of the current through the lamp from 2 to 6½ ampères increased the yield, but further rise of current diminished it, doubt because of the rise of temperature which it caused. Increase of the oxygen-stream corresponding to a rise from 2 to 4 ampères in the generating vessel nearly doubled the yield of ozone, but slightly decreased the percentage in the issuing gas. The effect of moisture in the oxygen was examined, but no conclusions on this matter can yet be drawn. The experiments indicate that the conversion of oxygen into ozone by ultraviolet light is opposed by the decomposition of ozone into oxygen, the speed of which reaction increases rapidly with rise of temperature, and they lend support to the view that the production of ozone in the Siemens tube is due to the influence of ultraviolet radiation.—J. T. D.

Electric Disintegration; Mechanism of —; Fusion of Carbon; Decomposition of Alloys. F. Braun. *Ann. der Physik*, 1905, **17**, 359–363. *Chem. Centr.*, 1905, **2**, 175.

the discharge from a battery of Leyden jars be led through a thin metal wire laid on a glass plate or between glass plates, the metal disintegrates, because for an instant it is heated to the point of vaporisation; the condensed vapour frequently occurs in the form of a very fine metallic network. The higher the melting point of the metal, the higher must the intensity of the charge be in order to produce the effect described. The author photographed the vaporisation of a tantalum (m.pt. 2200° C.) and a zinc wire; the same form of image was obtained in both cases. The spectrum of the vapour evolved was also photographed; it was in the form of a continuous spectrum, showing the more important zinc lines. Under similar conditions carbon gave a continuous spectrum; by the aid of the microscope globules of carbon could be distinctly recognised. Alloys such as brass (or of platinum and silver) can be treated by electric disintegration. The temperature is chosen so that the brass melts; the zinc is vaporised, it ejects particles of molten brass; during the flight of these particles, the zinc distils off, whilst the copper is deposited.—A. S.

Supersaturated Solutions; Speed of Crystallisation of —. C. Leenhardt. *Comptes rend.*, 1905, **141**, 188–189.

LEENHARDT has shown (*Z. physik. Ch.*, 1897, **23**, 526) that the speed with which solidification is propagated along a narrow tube of fused substance, while proportional to the number of degrees of over-cooling for small intervals, comes with further over-cooling constant, and decreases considerably again when the over-cooling is so great that the heat evolved by solidification cannot raise the liquid to its melting point. The author has found that the law is obeyed by the crystallisation of supersaturated solutions of salts (sodium sulphate, acetate, thiosulphate) in over-cooled. In the case of sodium acetate, for example, the speed of crystallisation of the solution cooled by the fusion of the crystallised salt is 0.7 cm. per hour for all temperatures between 25° and –20° C. This physical constant of the solution, independent of the diameter of the containing tube, and varying only with concentration of the solution. In the case of sodium sulphate this variation is expressible as follows:—The duration of the speed of crystallisation is proportional to the square root of the amount of anhydrous salt dissolved in a given amount of crystallised salt.—J. T. D.

Oxalates; Acid Ammonium —. P. T. Walden. *Amer. Chem. J.*, 1905, **34**, 147–152.

Solutions of oxalic acid and ammonium oxalate in varying proportions were made, containing more of the oxalates than would remain in solution at 25° C., and were then kept at that temperature, with frequent shaking, for 48 hours. The solution and the residue were then analysed. The different solutions leave a constant residue and separate out varying residues, save where a double salt is formed, in which case the solution varies and the residue is constant. The only two salts thus formed were:

In the case of each of these salts, its composition lay between the limiting compositions of the solutions from which it separated; hence it should be recrystallisable from aqueous solution. This was found to be so in each case.—J. T. D.

Oxalates of Lithium, Sodium, Potassium, and Caesium; Acid —. H. W. Foote and I. A. Andrew. *Amer. Chem. J.*, 1905, **34**, 153–164.

These salts were investigated by the same method which was used (see preceding abstract). The following were obtained:—

The solubilities of the normal oxalates in water and in oxalic acid of various strengths (or reciprocally that of oxalic acid in various normal oxalate solutions) were determined from the experiments, and plotted. From the curves so obtained it is possible to determine whether any given acid salt can or cannot be recrystallised from aqueous solution.—J. T. D.

Oxalates; Alleged Double —. H. W. Foote and I. A. Andrew. *Amer. Chem. J.*, 1905, **34**, 164–167.

From an examination of the behaviour of mixed solutions of the separate oxalates (see preceding abstracts) the authors conclude that none of the salts KNaC_2O_4 , $\text{NH}_4\text{KC}_2\text{O}_4$, $\text{NH}_4\text{LiC}_2\text{O}_4$, each of which is mentioned in chemical literature, has any real existence. Nor are there at 25° C. (and probably at any other temperature) any double oxalates of ammonium with magnesium, zinc, or cadmium, though several of these are mentioned.

—J. T. D.

Lipase. F. L. Dunlap and W. Seymour. *J. Amer. Chem. Soc.*, 1905, **27**, 935–946.

The experiments were made with peanuts (*Arachis*), linseed, almonds and croton seeds. In the resting state these seeds possess no, or only a very slight, lipolytic power; nor is the enzyme in these seeds made active by the presence of mineral acid during the digestion. The peanuts and linseed were also tested after germination, the germinated seeds being macerated to a paste. In this state a very considerable action was observed, showing that the enzyme lipase is developed during the process of germination. Extracts were made from the germinated seeds by triturating with sand and subjecting the mass to a pressure of 250 atmospheres; these expressed extracts contained lipase. Both the peanut and linseed extracts gave voluminous precipitates when poured into alcohol. The precipitate from the peanut extract after washing and drying contained the active lipase in a highly concentrated form, but the precipitate from the linseed extract was perfectly inactive. The authors express the opinion that the zymogen and the lipase of these seeds differ in character from those of the castor oil bean.—J. F. B.

CALCIUM CARBIDE REGULATIONS IN CEYLON.

Bd. of Trade J., Aug. 24, 1905.

The *Ceylon Government Gazette* for 21st July last, contains amended rules, made by the Governor of the Colony, to regulate the importation, storage, and transport of calcium carbide.

The rules, dated 8th February, 1902, are cancelled, and the importation is prohibited of calcium carbide which contains impurities liable to generate phosphoretted hydrogen or siluretted hydrogen so as to render the gas evolved liable to ignite spontaneously.

Acetylene, when liquid or when subject to a pressure above that of the atmosphere, capable of supporting a column of water exceeding 100 inches in height, and whether or not in admixture with other substances, shall be deemed to be dangerous, and shall be prohibited from being manufactured, imported, kept, conveyed or sold subject to the following exception:

Acetylene in admixture with oil gas in a proportion not exceeding 20 parts by volume of acetylene in every 100 parts of the mixture, when subjected to a pressure not exceeding 150 lbs. to the sq. in., shall not be deemed to be dangerous, provided that the acetylene and oil gas shall be mixed together in a chamber or vessel before the gases are subject to compression.

The rules under notice also direct that certain regulations are to be observed by the masters of vessels carrying calcium carbide, and provide regulations respecting the storage and transport of the article.

The full text of the rules may be seen at the Commercial Intelligence Branch of the Board of Trade, 73, Rasinghall Street, E.C.

VII.—ACIDS, ALKALIS, Etc.

CHEMICAL IMPORTS OF PORTUGUESE EAST AFRICA.

Chem. and Drug., Aug. 26, 1905.

During 1904 the imports of potassium cyanide into Lourenço Marques (in transit to the Transvaal) amounted to 2,513 tons (197,558*l.*) against 965 tons in 1903 and 673 tons in 1902. Germany sent more than twice as much as the United Kingdom last year, while in 1903 the United Kingdom sent through Lourenço Marques three times as much as Germany. Of mercury the imports were 56,974 lb. (7,705*l.*), and of this quantity the United Kingdom supplied 19,089 lb., Germany 7,285 lb., and Austria-Hungary 30,100 lb. The soap imports were: 1904, 2,006,427 lb.; 1903, 2,179,051 lb.; 1902, 888,099 lb. The 1904 imports included 20,592 lb. of toilet soap, the rest being common soap. Of the former the U.K. sent 12,810 lb., Austria-Hungary 4,300 lb., and Germany 1,400 lb.; of common soap, the U.K. sent 2,504,000 lb., U.S.A. 34,000 lb., and Germany 31,000 lb. Of essential oils, 12,739 lb. (858*l.*) were imported against 17,130 lb. during 1903; the U.K. supplied 9,342 lb. and Germany 2,322 lb. Chemicals and apothecaries' wares valued at 47,064*l.* were sent through to the Transvaal. These goods comprised 56 tons of alkali, 27 tons ammonia, 11 tons indigo, 9 tons benzine, 89 tons borax, 108 tons dextrin, 592 tons drugs, 689 tons sulphur (all from Italy), 35 tons magnesia, 28 tons medicines, 55 tons caustic soda, 53 tons bicarbonate of soda, 732 tons gypsum, and 57 tons chemical manure. The United Kingdom heads the list in everything but sulphur, benzine, gypsum, and manure. Of acids, 202,018 lb. were received. This amount included 110,000 lb. of carbonic acid and 92,016 lb. sulphuric acid. Of the former the United Kingdom supplied 3,000 lb., Germany 105,000 lb., and Belgium the remainder. The sulphuric acid was divided equally between the United Kingdom and Germany. In the supply of toilet soap to the Portuguese Colony of Lourenço Marques the United Kingdom has lost ground considerably, and Germany headed the list last year with 25,000 lb.

CRYOLITE IMPORTS OF UNITED STATES.

Mining World, Chicago, Aug. 12, 1905.

There was a large falling off in the quantity of cryolite imported into the United States in 1904. This amount to 959 long tons, valued at 13,708 dols., as against 77 long tons, valued at 102,879 dols., in 1903. This is the smallest quantity of cryolite imported into the United States since 1871. Since 1885 the importation has, except in 1896, been over 5000 long tons a year, and in 1887, 1894 and 1897 the importation was over 10,000 long tons a year.

X.—METALLURGY.

PIG IRON PRODUCTION OF CANADA FOR FIRST HALF OF 1905.

Bd. of Trade J., Aug. 24, 1905.

The American Iron and Steel Association has received from the manufacturers the statistics of the production of pig-iron in Canada in the first six months of 1905. The figures show a large increase as compared with either the two halves of 1904, as will be seen by the following table, which gives the production according to the fuel used in tons of 2,240 lbs., in half-yearly periods:—

Fuel used.	First half of 1904.	Second half of 1904.	First half of 1905.
	Tons.	Tons.	Tons.
Coke	111,840	139,831	188,541
Charcoal	8,803	10,468	21,661
Total	120,643	150,299	210,202

The Canadian production of pig-iron in the first half of 1905 was the greatest in any half year in the history of the Dominion, exceeding by 48,453 tons that of the last half of 1902, the next highest half year, when 161,338 tons were made. It was also greater than the production of any whole year prior to 1901. Down to that year the production of pig-iron in Canada never amounted to 100,000 tons in any calendar year.

The production of Bessemer pig-iron in the first half of 1905 amounted to 63,785 tons. There was no production of Bessemer pig-iron in the first half of 1904, and only 26,016 tons were made in the second half of that year. The production of basic pig-iron in the first half of 1905 amounted to 68,378 tons, against 28,981 tons in the first half of 1904 and 41,152 tons in the second half of 1904.

PIG-IRON PRODUCTION IN U.S.A.

Bd. of Trade J., August 17, 1905.

The *Bulletin* of the American Iron and Steel Association of Aug. 1, publishes the following statistics of the production of pig-iron in the United States of America during the first half of the current year, as compared with the first half of 1904:—

	First half of 1904.	First half of 1905.
	Tons of 2,240 lbs.	Tons of 2,240 lbs.
Bessemer pig-iron	4,143,364	5,930,791
Low phosphorus pig-iron	87,582	77,637
Basic pig-iron	1,061,901	1,968,591
Charcoal pig-iron	213,356	170,511
Spiegeleisen, ferro-manganese, ferro-phosphorus, and ferro-Bessemer pig-iron	114,510	129,041
Other kinds of pig-iron	2,252,725	2,888,601
Total	8,173,438	11,163,171

SMELTING WORKS: LABOUR REGULATIONS IN GERMANY —.

Eng. and Mining J., Aug. 12, 1905.

The *Reichsanzeiger* has just published an order of Bundesrat, relating to lead smelters, lead colour works and zinc smelters. The employment of males and youthful labourers in dust chambers, dust canals and in the transportation of the dust is prohibited; and such persons are not permitted to enter premises mentioned. The workmen employed at smelting furnaces, with the exception of those on the floor, are restricted to eight hours' work per day. The rule applies to the labourers employed in the interior of old stacks and in the cleaning of dust chambers and canals containing wet dust. Labourers engaged in cleaning dust chambers and dust canals containing dry are not permitted to work longer than four hours day in the interior of such chambers and canals, and more than eight hours per day in all. These rules go into effect Jan. 1, 1906, unless the public interest will be better subserved by waiting. In that case Bundesrat may extend the time to Jan. 1, 1913, and also modify the rules.

—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

CALCIUM, MAGNESIUM, AND ZINC PEROXIDES.

Mining World, Aug. 5, 1905.

Several new chemical products are being manufactured in an electric furnace at Niagara Falls. Calcium peroxide, made, contains from 60 to 65 per cent. of CaO_2 . It is used to use calcium peroxide for the sterilisation and preservation of foods. Magnesium peroxide contains 25 to 32 per cent. of MgO_2 and may be used in a similar manner to calcium peroxide. It may be utilised for sterilising water. Zinc peroxide contains from 50 per cent. ZnO_2 . It is said to make a good anti-cancer dressing.

XII.—FATTY OILS, FATS, Etc.

OLIVE OIL; ADULTERATION OF —.

Chem. and Drug., Aug. 19, 1905.

The result of a controversy between two local papers, *l'Étât Var* of Toulon, and *L'Éclair* of Nice, some interesting facts have come to light respecting the adulteration of olive oil in the very districts reputed to be home of this industry. The region of Nice is celebrated for the quality of its oil, and although there is stated annually from this centre something like 6 million litres, it is a fact that in the town of Nice itself it is comparatively difficult to get an oil which is unsophisticated; adulteration, which has been going on for years, was exposed last April, when the Syndicate of Grocers brought an action in the Tribunal Correctionnel de la Seine against certain firms for fraud. The principal centre of adulteration is a small town called Salon, situated between Marseilles and Avignon, at about 50 kiloms. from the first-named town, and from here the various adulterated oils are forwarded to all parts of France, and also abroad. The Tribunal of the Seine pronounced Judgment against the adulterators. The more important of the by-laws, &c., imposed upon members of the Olive Oil Syndicate of Nice, are the following:—
The merchants forming part of the Syndicate are prohibited from dealing in any other oil than that of the olive, consequently from mixing the oils. Any member of the syndicate convicted of having mixed seed oil with olive oil having dealt in seed oils, will be expelled from the syndicate and fined 10,000 fr.; this sum to be added to the fines of the Syndicate. No member of the Syndicate is permitted to trade in olive oil under more than one name or style, nor conduct branches, either wholesale or retail, under any assumed name.
In spite of all the protests there is carried on at Nice a great deal of blending of various qualities of olive oil. Oils arrive in the harbour from

various parts of the world. Large quantities come from Algiers and Tunis, from Spain and Italy. These are cheaper qualities, and have distinct characters and tastes, but are used to mix with various qualities of oil produced in the district in order to modify their flavour or appearance, and to diminish the cost. It frequently happens that an old oil perfectly sweet and good is improved by the addition of a young or green oil to pick up its flavour and give it more tone and body. This *coupage* corresponds to what is done in the wine trade, and is quite legal, although the product resulting from such an operation can scarcely be described as "pure olive oil from Nice," seeing that it is a mixture of Nice oil with cheaper kinds. The blending of seed oils with olive oil is done before the oils have been fined down. Both are mixed in a turbid state, and, after remaining in the earthenware vats to clear down, the oil so adulterated is pumped up into the "pile," as it is called, and the product is then filtered through cotton wool in the usual way, the result being an oil of a particularly bright and attractive colour and appearance, but by no means what is generally known as "huile vierge de Nice."

TRAIN OIL IN GERMANY.

For. Off. Misc. Series, No. 636.

The greater part of the total import of train oil into Germany is landed at Hamburg, and for many years past the bulk of it has come from Japan. The import from Japan sank, however, in 1903 from 53,357 to 35,013 casks, but it is to be observed that in this year there was a falling-off in the total import of this substance of nearly 30 per cent.

The total import of train oil into Germany during the years 1901, 1902 and 1903 was as follows:—

	Quantity.		
	1901.	1902.	1903.
	Cwts.	Cwts.	Cwts.
Hamburg	236,541	238,488	174,548
Stettin	39,954	39,103	28,093
Königsberg	11,412	12,669	12,021
Dantzic	7,739	15,449	9,246
Total	295,646	305,709	223,908

XIII.A.—PIGMENTS, PAINTS, Etc.

WHITE LEAD; CANADIAN DUTY ON —.

U.S. Cons. Rep., No. 2326, Aug. 4, 1905.

The Canadian Government has made known to the paint manufacturers of Canada that their requests with regard to the increased tariff on imports of dry white lead have been granted, and that all white lead coming into Canada up to September 15, 1905, will come in at the old tariff of 5 per cent., provided it was ordered previous to July 6, the date on which the new tariff of 30 per cent. was established.

The new tariff was made in response to an appeal from the recently organised Carter White Lead Company, which is preparing to manufacture in Montreal. Representatives of this company approached the Government and pointed out that there were no manufacturers of white lead in Canada, and that provided they could have a sufficiently protective tariff they would set up a manufactory in Montreal.

The imports of dry white and red lead, orange mineral, and zinc white for the year ending June 30, 1904, were upwards of 17,000,000 lb., valued at 666,365 dols. Of this amount there was imported from the United States 7,617,000 lb., Germany 5,173,000 lb., and the United Kingdom 3,491,000 lb.

The increase of duty on white lead will naturally affect the importations into Canada of paints, which amounted, during the year ended June 30, 1904, to 9,338,446 lb., valued at 451,481 dols., of which amount 6,278,492 lb., valued at 290,130 dols., came from the United States.

XIII.—INDIA-RUBBER, *Etc.*

INDIA-RUBBER AT PARA.

Bd. of Trade J., Aug. 24, 1905.

H.M. Consul at Para has forwarded the following particulars of the supply and shipment of india-rubber in that district:—

The percentages of qualities calculated on the figures of the 17 preceding years are as follows:—

Fine 55 per cent.	coarse 25 per cent.
Medium 10 ..	Caucho 10 ..

The qualities shipped during 1904-5 show a 5 per cent. decrease in the proportion of fine, and a 7 per cent. increase in caucho.

Para produced, as usual, about one-third of the total supply, but dealt with almost one-half of the entire shipments during the year ended 30th June, 1905.

The origin of the 1904-5 crop was as follows:—

	Tons.
States of Amazonas and Matto Grosso and Peru and Bolivia (including 4,613 tons caucho)	22,086
State of Para (including 515 tons caucho)	11,288
Total	33,374

It is to be noted that the port of Para handled the whole of the Para crop, as well as 5,267 tons of the up-river crop. Caucho is now regularly sent to the port of Para from the River Tocantins district.

XIV.—TANNING: LEATHER: GLUE, *Etc.*

MANGROVE BARK AT ANGOLA.

For. Off. Ann. Series, No. 3478.

The British Acting-Consul at Loanda states that a sample of mangrove bark was sent to the United Kingdom to ascertain if it were of any use for tanning. The report on it showed:—

	Per cent.
Tanning matters absorbed by hide	15.7
Soluble non-tanning matters	5.3
Insoluble (at 60° F.)	63.0
Water	16.0
Total	100.0

It was stated, however, that as this sample was taken from old wood it may not have been of average quality, and that further experiments will be made. If this bark prove to have a commercial value good business should result, as there is a large quantity of it available.

XV.—MANURES, *Etc.*

FERTILISERS IN MARSEILLES.

U.S. Cons. Rep., No. 2330, Aug. 9, 1905.

The most important article imported into France for fertilising purposes is rock phosphate, the greater part of which is received from Algeria. Thus in 1902, the latest year for which complete figures are immediately available, the total French importation amounted to 305,130 tons, of which amount Algeria supplied 173,461 tons. In 1904 Marseilles received 24,563 tons of phosphate and in the year ended June 30, 1904, Cete received 57,050 tons, of which the United States furnished 10,477 tons. At present phosphate rock sells in Marseilles at 10.05 cents. per unit of phosphate per ton.

The following table sets forth the importations at Marseilles during 1904 of the principal fertilisers:—

	Kilos.
Rock phosphate	24,563,435
Incinerated bone ashes	891,750
Decalcinated bone dust	11,203,549
Sulphate of copper	1,844,376
Sulphate of potash	442,430
Chloride of potassium	593,640
Nitrate of potash	1,993,751
Kainite	190,809
Nitrate of soda	5,939,270
Bisulphate of potash	12,539

One of the most important items in the foregoing nitrate of soda. Three-quarters of the total amount reaching France is received at Dunkerque from Chili. Prices are so variable that professors of agriculture advising farmers only to employ it when it furnishes nitrogen at a lower cost than sulphate of ammonia.

French potassium chloride averages from 56 to 57 per cent. of potash. At present, owing to German competition the refining operations are pressed less far, and the potassium chloride contains from 78 to 82 per cent. of KCl , or an average of 50 per cent. of potash. The German chloride comes from Stassfurt, and contains from 80 to 85 per cent. of KCl , or 50 to 53 per cent. of potash.

Desultory attempts have been made to import American copper sulphate into France, but owing to the excessive duty of 1 fr. per 100 kilos, which American copper sulphate pays, the American offerings must be by that amount lower than those from Spain and England. At the present time this article is quoted at 8.78 dols. per 100 kilos. c. Marseilles from England or Spain, or 9.65 dols. per 100 kilos, duty paid.

Marseilles is a producing point for large quantities of oil cake and meal used for fertilising purposes.

FERTILISERS IN CHINA.

U.S. Cons. Rep. No. 2335, Aug. 15, 1905.

The U.S. Consul at Amoy describes an extensive business enterprise started under American auspices for supplying fertilising material to China. He says there is an unlimited field for the sale of good and cheap fertilising material, and that the Chinese people are already regarding this enterprise with favour. The enterprise will probably take the form of a Hong Kong corporation, because Hong Kong would give a more favourable charter than can be had in the United States. At present the Chinese are using for fertilisers anything that can be had. The principal one is bean cake, of which port of Nanchang alone ships to Lower Chinese ports 5,000,000 dols. worth in gold a year.

In addition to the amount of bean cakes sold in China the country is accustomed to ship about 3,800,000 dols. worth a year abroad, mostly to Japan, but the importation interfered considerably with the sale of last year. On the other hand, it is already importing a considerable amount of commercial fertiliser. Manure cake, potash cake and other varieties aggregated close to 25,000 dols. gold, in addition to the 900,000 dols. of bean cake imported into Amoy alone last year.

XVI.—SUGAR, STARCH, *Etc.*

BEETROOT SUGAR PRODUCTION IN EUROPE.

For. Off. Ann. Series, No. 3480.

The following table gives particulars of the production, export and consumption, &c., of beetroot sugar in 1904, those European countries responsible for the enormous over-production:—

Country.	Quantity.		
	Production.	Consumption.	Export.
	Tons.	Tons.	Tons.
Germany	1,929,415	800,000	1,129,415
Austria-Hungary	1,158,800	400,000	758,800
Russia	1,154,299	886,000	268,299
France	794,431	420,000	374,431
Belgium	202,850	85,000	117,850
Netherlands	123,500	90,000	33,500
Total	5,363,295	2,681,000	2,682,295

The United Kingdom consumes over 1,700,000 tons of beetroot sugar per annum, accounting for very nearly one-third of the total production of Europe, notwithstanding the sugar tax of 2s. 10d. per cwt. upon

cent. polarisation sugar, the price of sugar is cheaper the United Kingdom than it is in any of the actual root sugar producing countries.

XVII.—BREWING, WINES, SPIRITS, &c.

SPIRIT DENATURING IN RUSSIA.

For. Off. Ann. Series, No. 3480.

The Russian Government having sanctioned the use of denatured spirit for illuminating, heating and other purposes, an opening for lamps to burn spirit instead of petroleum is thereby presented. Such lamps have been imported from Germany, but are not yet perfect. There is also demand for small-sized stationary engines, traction motors, motor-cars using denatured spirit as fuel. Nearly every fairly-sized estate owns its own distillery, and as the production of rye spirit is not very costly, and no duty is levied by the Government upon it in its denatured state, landowners and farmers are anxious to make use of it as fuel. One small-sized stationary motor of 10-horsepower which has been imported into the Kiev district, and has proved eminently successful. A portable sized spirit-driven motor, powerful enough to run ordinary grinding mills, small threshing machines, cutters, ploughing and reaping machinery, would find a ready sale.

XVIII.A.—FOODS.

MEAT PRESERVATIVE; DANGEROUS —.

U.S. Cons. Rep., No. 2338, Aug. 18, 1905.

The President of the Berlin police has issued the following warning, which has been published in various German newspapers.

A preserving substance under the name of "sterilisol" has been put upon the market, with the statement that no objection can be found to its application and that it is in no way injurious to health. Contrary to this it has been shown by investigations made by the chemical laboratory of the Imperial Health Office that samples of this preparation contain $2\frac{1}{2}$ per cent. of formaldehyde. According to the opinion of the royal scientific deputation for medical research, as well as all preparations which contain formalin to be considered as preservatives seriously injurious to health in all articles of nourishment and enjoyment. The preparation of meat for sale the application of formaldehyde has been expressly forbidden by statutory regulations.

XX.—FINE CHEMICALS, &c.

MORPHIA AND FLOUR IN CHINA.

U.S. Cons. Rep., No. 2338, Aug. 18, 1905.

Attempts to smuggle morphia, concealed in a flour shipment, resulted in the death of a number of natives in Amoy the up-country districts, and has made the Customs authorities more vigilant.

1,906 oz. of morphia were imported in 1902, owing to impending introduction of the tariff, and 3,101 oz. in 1903, which still paid the old 5 per cent. *ad valorem* duty, but only 8 oz. were reported this year. The market value of morphia at this present moment is still below 100 taels per ounce, the duty which it is supposed to pay. There is not the least doubt that this dangerous drug is still in great vogue among the Chinese, and that the duty has not in any way stopped its importation. It simply induced the smuggling of this very easily detectable poison.

CHEMICAL ANALYSIS OF ARTICLES IMPORTED INTO TURKEY.

Bd. of Trade J., Aug. 24, 1905.

The *Bulletin de la Chambre de Commerce française de Constantinople* contains the text of the new Turkish Law relating with the chemical analysis of articles of consumption imported into Turkey.

The following are the principal provisions of this Law:

The goods subject to sanitary inspection and analysis by the Customs are (1) chemical and pharmaceutical preparations and specialties; (2) butter, oil, and flour; (3) coffee and tea; (4) liquors and alcoholic beverages.

With regard to chemical and pharmaceutical preparations and specialties, the Law prohibits the importation of medicines of which the composition is unknown or whose purity is below the standard established in the pharmaceutical code adopted by the Imperial Government. However, medicines of unknown composition will be admitted if accompanied by a certificate from an official academy or recognised institution or body having an official character, and by a list enumerating the substances composing the medicine, without specifying the quantity of each substance employed, provided that the chemical analysis made by the Customs shows the preparation to be free from all prohibited materials. The importation of specialties prepared with certain chemical drugs (*e.g.*, cocaine and *Cannabis Indica*), as also of chemical substances, such as chlorate of potash or soda, picrates, and nitro-glycerin, which are used in the manufacture of explosives, is prohibited; but, so far as regards the latter class of materials, those substances of indispensable use in medicine, such as chlorate and nitrate of potash and of soda, or which are employed for agricultural and industrial purposes, will be furnished to chemists, &c., in fixed quantities by the authorised departments. Moreover, it is permitted to import chlorate of potash, &c., in a form unfitted for the manufacture of explosives, such as, for example, in the form of medicinal lozenges.

Patent List.

N.B.—In these lists, [A.] means "Application for Patent," and [C.S.] "Complete Specification Accepted."

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

- 18,194. (1904) Brossard. Apparatus for dyeing, cleaning and washing. Aug. 30.
- 19,953 (1904). Mycock. Apparatus for guiding or distending textile piece goods in bleaching, printing and drying. Aug. 30.
- 21,988 (1904). Imray (Farbwerke vorm. Meister Lucius und Brüning). Manufacture of silk-like threads. Aug. 30.
- 22,614 (1904). (Ehmann). See under II.
- 25,284 (1904). Johnson (Badische Anilin und Soda Fabrik). Manufacture of pastes for the discharge of dyed textile fabrics. Sept. 6.
- 406 (1905). Imray (Meister, Lucius und Brüning). Manufacture of blue dyestuffs by oxidation on the fibre. Sept. 6.
- 1367 (1905). Shillito (Geigy). Production of light fast violet to blue shades on wool. Aug. 23.
- 7020 (1905). Kother. See under XI.
- 12,169 (1905). Johnson (Badische Anilin und Soda Fabrik). Manufacture of discharging pastes for use in the discharging of dyed textile fabrics. Aug. 23.

VI.—COLOURING WOOD, PAPER, LEATHER, Etc.

- [A.] 17,163. Tittel. Apparatus for supplying colouring matter, mixture, solutions, or colour-producing chemicals in paper-making machines for the manufacture of one side coloured, clouded, coloured and marbled papers.* Aug. 21.
- 17,338. Lamb and Rennie. Printing on leather.* Aug. 28.

VII.—ACIDS, ALKALIS, AND SALTS.

- [A.] 16,929. Raschen, Waring, Shores, and United Alkali Co. Treatment of arsenical sulphuric acid for the separation of arsenic and the obtainment of arsenious chloride. Aug. 21.
- 16,930. Raschen, Waring, Shores, and United Alkali Co. Treatment of arsenious chloride for the obtainment of arsenious acid therefrom. Aug. 21.
- 16,931. Raschen, Waring, Shores, and United Alkali Co. Treatment of arsenical sulphur ores for the obtainment of arsenious acid and of sulphuric acid deprived of arsenic. Aug. 21.
- 17,042. Harger. Removing impurities from inferior kinds of graphite and obtaining valuable products therefrom. Aug. 23.
- 17,198. Hurlbutt and Hurlbutt. Packing materials for hydrochloric acid towers and other acid towers. Aug. 25.
- 17,267. Langlands and O'Connor. Apparatus for making sulphate of ammonia. Aug. 26.
- [C.S.] 17,794 (1904). Lake (Soc. Anon. Ing. I. Vogel per la Fabbricazione di Concimi Chimici). Manufacture of sulphuric acid. Aug. 23.
- 20,835 (1904). Hargreaves. Generation and application of chlorine. Sept. 6.
- 4353 (1905). Nietenführ. Process of manufacturing nitric acid. Aug. 30.

VIII.—GLASS, POTTERY, AND ENAMELS.

- [A.] 17,292. Wagner and Hermsdorf. Process for enamelling iron or steel goods. Aug. 26.
- [C.S.] 24,626 (1904). Sankey. Enamelling metallic surfaces. Aug. 30.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

- [A.] 248a. Matas y Rodés. Manufacture of compositions or agglomerates of cork.* [Jan. 2, 1905, under Rule V.] Aug. 22.
- 16,530. Walker. Manufacture of cement. Aug. 15.
- 16,744. Koemann and Kaufmann. Manufacture of substances capable of resisting water, chemical influences, and similar materials.* Aug. 18.
- 16,841. Richards. Cement for attaching glass or pottery tiles to bricks, walls, and other surfaces. Aug. 19.
- 16,983. Shoop. Construction and arrangement of lime kilns. Aug. 21.
- 17,020. Woakes. Eliminating silicates and other cementing elements from earths or soils containing the same. Aug. 22.
- 17,109. Wynne. Manufacture of hydraulic cement. Aug. 24.

- [A.] 17,743. Clarke. Manufacture of bricks. Sept. 1.
 [C.S.] 17,736 (1904). Powell. Wood and vulcanising or hardening, preserving and treating same. Aug. 23.
 .. 22,056 (1904). Castle. Manufacture of cement. Aug. 23.
 .. 26,516 (1904). Standt. Manufacture of artificial stone compositions. Sept. 6.

X.—METALLURGY.

- [A.] 16,643. Hernadthaler Ung. Eisenindustrie A.G., and Primosigh. Treatment of iron ores.* Aug. 16.
 .. 16,896. Newton (Somers). Furnaces. Aug. 21.
 .. 16,897. Newton (Somers). Process and apparatus for making thin plate. Aug. 21.
 .. 17,114. Lizzett. Regenerative gas furnaces for melting steel and the like. Aug. 24.
 .. 17,123. Hobson. New alloy. [U.S. App., Feb. 27, 1905.]* Aug. 24.
 .. 17,174. Hadfield. Manufacture of armour plates.* Aug. 24.
 .. 17,175. Cloud (McMurtry and Rogers). Treatment of ores, mattes, regulus, or the like metallurgical products and more especially those containing copper, for effecting the disulphurisation thereof and the obtaining of products suitable for smelting in blast furnaces. Aug. 24.
 .. 17,178. Gredt. Treatment of ores.* Aug. 24.
 .. 17,250. Windhausen. Process and apparatus for treating ores and metals. Aug. 25.
 .. 17,310. Hobson. Selective solvents for silver.* Aug. 26.
 .. 17,325. Swinburne. Treatment of poor ores. Aug. 28.
 .. 17,370. Leggo. Furnace for treating ores, &c. Aug. 28.
 .. 17,449. Chance. Process for purifying metals. Aug. 29.
 .. 17,534. Jenkins. Plastic composition for binding minerals. Aug. 30.
 .. 17,561. Boulton (Sutton, Steele and Steele). Dry concentration of ores. Aug. 30.
 .. 17,651. Leitch. Furnaces for separating metals.* Aug. 31.
 .. 17,654. Boulton (Sutton, Steele and Steele). Dry concentration of ores.* Aug. 31.
 [C.S.] 18,660 (1904). De Bavay. Process for separating by flotation zinc blende from ores, tailings and concentrates, and for preparing such ores. Sept. 6.
 .. 22,659 (1904). Morgan Crucible Co., Ltd., and Speirs. Compound for brushes of dynamo electric machines, bearings, &c. Sept. 6.
 .. 22,688 (1904). Zohrab. Manufacture of steel and the smelting and reduction of iron or other ores or metals. Aug. 30.
 .. 24,445 (1904). Witter. Process for obtaining and utilising tin from tin slags. Aug. 30.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

- [A.] 16,681. Craig. Apparatus for the production of ozone from oxygen or atmospheric air, and its application for various purposes. Aug. 17.

- [A.] 16,935. Cowper-Coles. Production of plates for printing purposes. Aug. 21.
 .. 16,936. Cowper-Coles. Electrolytic manufacture of copper wire strip or the like. Aug. 21.
 .. 17,152. Clarke. Apparatus for agitating electrolyte, alkaline or other solutions during electroplating, depositing, boiling, or mixing process. Aug. 24.
 .. 17,238. Joel. Electrodes for secondary battery. Aug. 25.
 .. 17,727. Lewis and Corey. Deposition of metal. Sept. 1.
 [C.S.] 11,920 (1904). Bruno. Manufacture of electrodes for electric accumulators. Sept. 6.
 .. 24,166 (1904). Monterde. Electric accumulator. Sept. 6.
 .. 7020 (1905). Kother. Electrodes for electrolysis used in the manufacture of bleaching liquor. Sept. 6.
 .. 14,333 (1905). Girod. Electric furnaces. Sept. 6.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

- [A.] 17,777. Heys. Detergent and the manufacture thereof.* Sept. 2.
 [C.S.] 24,440 (1904). Holoubek. Manufacture of soap and apparatus therefor. Aug. 23.
 .. 1040 (1905). Silcock, Silcock and Stevenson. Process for extracting oil from seeds and the like. Sept. 6.
 .. 8696 (1905). Caldwell. Processes for expressing oil or other liquids from material. Sept. 6.
 .. 11,444 (1905). Da Cruz and Cardoso. Candles. Sept. 6.
 .. 11,679 (1905). Hennequin and Cayeux. Lamps. Aug. 23.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES, AND INDIA-RUBBER, ETC.

(A.)—PIGMENTS, PAINTS.

- [A.] 16,490. Brunet. Manufacture of arsenic and antimony colours, white antimony, lithopone, antimony white, yellow and red sulphid of antimony or minimum of antimony. [Fr. A. 344,444. April 15, 1905.]* Aug. 14.
 .. 16,787. Ruch. Process of manufacture of pigments, varnishes, and the like.* Aug. 18.
 .. 16,840. Earle. Colour washes for brickwork. Aug. 19.
 .. 16,951. Jones and Taylor. Non-corrosive pigments. Aug. 22.
 .. 17,057. Shepherd. Water-proofing composition. Aug. 23.
 .. 17,144. Fraser. Obtainment of zinc compounds for use as pigments. Aug. 24.
 .. 17,639. Evangelidi. Paint for ships' bottoms. Aug. 31.
 [C.S.] 24,238 (1904). Gebr. Heyl und Co., and Witzel. Manufacture of white lead. Sept. 6.
 .. 26,908 (1904). Johnson (Badische Anilin und Soda-Fabrik). See under IV.
 .. 26,909 (1904). Johnson (Badische Anilin und Soda-Fabrik). See under IV.

(B.)—RESINS, VARNISHES.

17,187. Morris. Substitute for felt, linoleum, oilcloth, leather, and the like.* Aug. 25.

(C.)—INDIA-RUBBER, ETC.

17,452. Neilson. Process for regenerating rubber waste of all kinds. Aug. 29.

17,717. Price. Refining or purifying india-rubber, gutta-percha, balata, &c. Sept. 1.

330 (1905). Thomson (Michie and Colledge). Method of separating or coagulating india-rubber and appliances therefor. Aug. 23.

—TANNING, LEATHER, GLUE, SIZE, ETC.

16,887. Granville. Process for dressing skins. Aug. 21.

17,187. Morris. *See under XIII B.*

17,551. Baron and Aubert. Process of tanning leather and skins. [Fr. Appl., Oct. 14, 1904.]* Aug. 30.

XV.—MANURES, ETC.

17,038. Furse. Obtaining manure and fuel out of house refuse, furnace refuse, or any other refuse. Aug. 23.

XVI.—SUGAR, STARCH, GUM, ETC.

16,589. Boidin. Process for rendering the hydrates of carbohydrates in general soluble.* Aug. 15.

17,554. Bertels. Processes for the purification of sugar juices. Aug. 30.

17,718. Baker and Ling. *See under XVII.*

3827 (1905). Robin-Langlois. Machines for manufacture of sugar. Aug. 23.

XVII.—BREWING, WINES, SPIRITS, ETC.

16,507. Coffey. Means and apparatus for separating and removing fusel oil in the process of distilling. Aug. 14.

17,718. Baker and Ling. Method of utilising starch as a malt adjunct in brewing and distilling. Sept. 1.

18,013 (1904). Deichmann and Deichmann. Malting processes. Aug. 30.

23,597 (1904). Rüksam. Process of preparing beer wort. Sept. 6.

5930 (1905). Pampe. Process for separating by products of alcoholic fermentation from mash or wort. Aug. 30.

13,022 (1905). Petersen-Schepeler und Schwanenflügel. Preliminary treatment and ageing of spirits. Aug. 23.

XVIII.—FOODS; SANITATION, WATER PURIFICATION; & DISINFECTANTS.

(A.)—FOODS.

16,478. Scholvien. Non-alcoholic beverages resembling beer. [Ger. Appl., Aug. 14, 1904.]* Aug. 14.

[A.] 16,609. Hawliczek. Preservation of meats. Aug. 16.

„ 16,681. Craig. *See under XI.*

„ 16,916. Kyle. Means for and method of preventing decomposition of fish.* Aug. 24.

„ 17,339 Paudler. Substitute for coffee. Aug. 28.

„ 17,623. Kathwimer's Malzkaffee-Fabrik. GmbH. Manufacture from grain or malt of a product resembling coffee. [Ger. Appl., Sept. 6, 1904.]* Aug. 31.

„ 17,641. Gates (de Kunwald). Manufacture of extract of coffee. Aug. 31.

[C.S.] 23,576 (1904). Roberts. Process for restoring to flour certain properties lost in milling. Sept. 6.

„ 26,174 (1904). Overbeck. Separating arsenic from liquid food materials. Sept. 6.

„ 6939 (1905). Broeker. Means for bleaching cereals and grain. Sept. 6.

„ 7830 (1905). Langer. Process for producing blood albumen preparations. Aug. 30.

„ 7982 (1905). Glas. Manufacture of soluble milk powder. Aug. 30.

„ 15,311 (1905). Mann. Process for the manufacture of butter substitutes such as margarine and the like. Aug. 30.

(B.)—SANITATION; WATER PURIFICATION.

[A.] 17,383. Vogelsang. Purification or filtration of sewage. [Ger. Appl., Sept. 1, 1904.]* Aug. 28.

XIX.—PAPER, PASTEBOARD, ETC.

[A.] 16,466. Rivers. Process of compacting liquid or fibrous pulp and other material.* Aug. 14.

„ 16,583. Peessarer. Process for the preparation of threads, films and laminæ from viscose.* Aug. 15.

„ 17,163. Tittel. *See under VI.*

„ 17,164. Friedrich. Manufacture of solutions of cellulose.* [Ger. Appl., Aug. 25, 1904.] Aug. 24.

[C.S.] 22,381 (1904). Parkin and Williams. Process for rendering celluloid or nitric cellulose compounds non-inflammable. Aug. 30.

„ 10,319 (1905). Garbin, Gérard and Gérard. Process and apparatus for utilising the waste of celluloid and similar substances. Sept. 6.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

[A.] 16,723. Ellis (Chem. Fab. von Heyden A. G.). Manufacture of guaiacol sulphonic acids and salts thereof.* Aug. 17.

„ 17,162. Imray (Meister, Lucius und Brüning). Manufacturer of aminobenzoic acid alkamine esters and derivatives thereof. Aug. 24.

„ 17,374. Newton (Bayer and Co.). Manufacture of a new iodine preparation. Aug. 28.

„ 17,511. Knoll und Co. Process of manufacturing neutral acid esters of sandal wood oil. [Ger. Appl., Feb. 10, 1905.]* Aug. 30.

[C.S.] 19,411 (1904). Zimmermann (Chem. Fab. auf actien, vorm. E. Schering). Manufacture of dialkylated barbituric acids. Aug. 30.

„ 2031 (1905). Imray (Meister, Lucius und Brüning). Manufacture of dialkylbarbituric acids. Sept. 6.

- [C.S.] 4055 (1905). Newton (Bayer und Co.). Manufacture of a new pharmaceutical compound. Aug. 30.
- .. 9114 (1905). Valentiner. Manufacture of salicylic acid methylene acetate. Aug. 23.
- .. 13,347 (1905). Maschmeyer. Manufacture of substances with the odour of violets. Sept. 6.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

- [A.] 16,999. Smith. Photographic film. Aug. 22.
- .. 17,303. Hoffsummer. Manufacture of photographic papers.* Aug. 26.
- .. 17,638. Grünbaum. Photographic three and four colour printing processes.* Aug. 31.
- [C.S.] 24,987 (1904). Newton (Bayer und Co.). Flash light. Sept. 6.

- [C.S.] 11,077 (1905). Pfanz. Preparation of photographic printing papers or surfaces. Aug. 30.

XXII.—EXPLOSIVES. MATCHES, Etc.

- [A.] 16,514. Macnab, and Ammonal Explosives I Explosives. Aug. 14.
- .. 17,741. Schneider. Explosive coherer-power [Ger. Appl., Oct. 27, 1904].* Sept. 1.
- [C.S.] 17,880 (1904). Boyd. Manufacture of explosive compositions. Aug. 23.
- .. 18,269 (1904). Le Brocquy. Manufacture of cord. Aug. 23.
- .. 13,340 (1905). Claessen. Manufacture of prim compositions and charges for shells and torpedoes. Sept. 6.

XXIII.—GENERAL ANALYTICAL CHEMISTRY

- [A.] 17,708. Hartung. Apparatus for use in analysis. [Ger. Appl., Sept. 2, 1904].* Sept.

JOURNAL OF THE Society of Chemical Industry.

A RECORD

FOR ALL INTERESTED IN CHEMICAL AND ALLIED MANUFACTURES.

ISSUED TWICE A MONTH.

No. 18.—Vol. XXIV.

SEPTEMBER 30, 1905.

No. 18.—Vol. XXIV.

Subscription of Members 25 - per annum;
Entrance Fee 21 -;
Election by the Council.

Price to Non-Members 36 - per annum;
To Members 25 - per Set of extra or back numbers.
Single copies (Members and Subscribers only)
1882—1901, 2 6 each; 1902 *et seq.*, 1 0 each.

he Society of Chemical Industry.

Past Presidents:

Sir Henry E. Roscoe, B.A., D.C.L., LL.D., Ph.D., F.R.S.	1881—1882.
† Sir Frederick A. Abel, Bart., K.C.B., G.C.V.O., D.C.L., D.Sc., F.R.S.	1882—1883.
† Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, LL.D., Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Sir James Dewar, M.A., LL.D., F.R.S.	1887—1888.
Ludwig Mond, Ph.D., F.R.S.	1888—1889.
† Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
† E. Rider Cook	1890—1891.
J. Emerson Reynolds, M.D., F.R.S.	1891—1892.
Sir John Evans, K.C.B., D.C.L., LL.D., Sc.D., F.R.S.	1892—1893.
† E. C. C. Stanford	1893—1894.
† E. Thorpe, C.B., LL.D., Sc.D., Ph.D., F.R.S.	1894—1895.
Thomas Tyrer	1895—1896.
† Edward Schunck, Ph.D., F.R.S.	1896—1897.
Frank Clowes, D.Sc.	1897—1898.
George Bellby	1898—1899.
† F. Chandler, D.Sc., M.D., Ph.D., LL.D.	1899—1900.
† J. W. Swan, D.Sc., M.A., F.R.S.	1900—1901.
van Levinstein	1901—1903.
† Sir W. Ramsay, K.C.B., D.Sc., LL.D., F.R.S.	1903—1904.
† Wm. H. Nichols, M.S., LL.D., D.Sc.	1904—1905.

† Deceased.

LIST OF COUNCIL, 1905—1906.

President: Dr. Edw. Divers, F.R.S.

Vice-Presidents:

Dr. J. Baekeland.	Dr. J. Lewkowitsch.
† Sir J. Bell.	N. H. Martin.
† Sir J. Lubentz.	Max Muspratt.
W. R. E. Hodgkinson.	Dr. Wm. H. Nichols.
† Howard.	T. J. Parker.
Levinstein.	Sir Wm. Ramsay, K.C.B., F.R.S.

Ordinary Members of Council:

T. Dunn.	Dr. K. E. Markel.
Guttmann.	B. E. R. Newlands.
Smewingway.	Prof. W. J. Pope, F.R.S.
W. R. Lang.	Sir Boverton Redwood.
Liog.	Walter F. Reid.
McArthur.	Dr. W. S. Squire.

Sectional Chairmen and Secretaries:

BIRMINGHAM.	F. R. O'Shanghnessy.
† Percy F. Frankland, F.R.S.	ALFRED BURTON.
J. Smale.	LIVERPOOL.
W. Carey.	W. Roscoe Hardwick.
Edon Salamon.	LONDON.
H. Bailey.	Julian L. Baker.
E. Louis.	MANCHESTER.
† Howard.	Julius Hübner.
† Wm. Moore.	NEWCASTLE.
C. Paton.	Dr. F. C. Garrett.
Perry.	NEW ENGLAND.
Liversidge, F.R.S.	Dr. W. H. Walker.
R. Procter.	NEW YORK.
	Dr. H. Schweitzer.
	NOTTINGHAM.
	S. R. Trotman.
	SCOTTISH.
	Dr. Thos. Gray.
	SYDNEY, N.S.W.
	T. U. Walton.
	YORKSHIRE.
	Thos. Fairley.

Honorary Treasurer:
Samuel Hall, East London Soap Works, Bow, E.

Hon. Foreign Secretary:

Dr. Ludwig Mond, F.R.S.

General Secretary:

Charles G. Cresswell, 59, Palace Chambers, Westminster, S.W.

THE JOURNAL.

Publication Committee:

The President.

Julian L. Baker.	Charles A. Kene, M.Sc., Ph.D.
G. Beilby.	Ivan Levinstein.
J. Carter Bell.	J. Lewkowitsch, Ph.D.
Joseph Bernays, M.I.C.E.	A. R. Ling.
H. Brunner.	W. Macnab.
Sir John Evans, K.C.B., F.R.S.	N. H. Martin.
T. Fairley.	B. E. R. Newlands.
Prof. A. G. Green.	John Pattinson.
Samuel Hall.	Prof. W. J. Pope, F.R.S.
John Heron.	F. B. Power, Ph.D.
D. B. Hewitt, M.D.	Prof. H. R. Procter.
Prof. W. R. E. Hodgkinson, Ph.D.	Sir Wm. Ramsay, K.C.B., F.R.S.
E. Grant Honper.	Sir Boverton Redwood, D.Sc.
David Howard.	Walter F. Reid.
Julius Hübner.	John Spiller.
Prof. A. K. Huntington.	W. S. Squire, Ph.D.
Wm. Kellner, Ph.D.	L. T. Thorne, Ph.D.
	Thomas Tyrer.

Editor:

Watson Smith, 34, Upper Park Road, Haverstock Hill, N.W.

Assisted by the following Staff of Abstractors:

D. Bendix	III.	G. W. Macdonald,	XXII.
E. Bentz	IV., V., VI.	M.Sc.	
J. O. Braithwaite	XX.	N. H. J. Miller, Ph.D.	XV.
J. F. Briggs	XVI., XVII., XIX., XX.	C. A. Mitchell,	XII., XXII.
T. F. Burton,	III., XX., XXI., B.Sc.	B.A.	
W. A. Caspari, Ph.D.	XI.	R. W. Moore	Trade Report.
W. H. Coleman	I., III., VII.	Barker North	V., XI.
J. H. Collins	X.	T. H. Pope,	XVI., XVII., XX., XXI.
J. T. Dunn, D.Sc.	VII., X.	F. W. Renaut	Index.
Ernest Feilmann,	IV., V., XX.	Chas. Salter	II., III., IX.
Walter C. Hancock, B.A.	IX.	M. J. Salter	XIII.
R. S. Hutton, D.Sc.	XI.	F. Shedden	XX.
H. Levinstein, Ph.D.	IV., V., VI., XX.	A. Shonk	III., VII., X., XI.
A. G. Levy, B.Sc.	VIII., IX.	W. P. Skertchley	XII., XVIII.
		E. Sonstadt	III., VII., X., XV.
		A. B. Steven, B.Sc.	IV., V.
		L. J. de Whalley, B.Sc.	XVI.

Birmingham Section.

Chairman: Percy F. Frankland.

Vice-Chairmen:

W. Waters Butler, Frank E. Lott, Alex. E. Tucker.

Committee:

Robt. B. Batty.	Edward Jackson.	T. Slater Price.
Wm. B. Davidson.	Thos. Lawton.	Walter Rosenhain.
Alex. Findlay.	Alex. McKenzie.	Harry Silvester.
Henry L. Heathcote.	Frank Platten.	Thos. Turner.

Hon. Local Secretary and Treasurer:

F. R. O'Shaughnessy, Tyburn, nr. Birmingham.

Canadian Section.

Chairman: F. J. Smale.

Vice-Chairmen:

W. H. Ellis, A. McGill, B. J. Harrington.

Committee:

J. H. Bowman.	Chas. H. Heys.	M. J. Taylor.
Jeffrey H. Burland.	W. R. Lang.	Harold Vander Linde.
Thos. Davies.	W. Lash Miller.	W. H. Van Winckel.
Milton L. Hersey.	Jas. P. Murray.	

Hon. Local Secretary:

Alfred Burton, 44, York Street, Toronto.

Liverpool Section.

Chairman: Eustace Carey.

Vice-Chairman: Frank Tate.

Committee:

T. Lewis Bailey.	J. T. Conroy.	C. Longuet Higgins.
J. Campbell Brown.	H. E. Davies.	E. L. Peck.
Arthur Carey.	A. Foden.	W. Collingwood
G. C. Clayton.	G. Watson Gray.	Williams.

Hon. Treasurer: W. P. Thompson.

Hon. Local Secretary:

W. R. Hardwick, 13, Batavia Buildings, Hackins Hey, Liverpool.

London Section.

Chairman: A. Gordon Salamon.

Vice-Chairman: R. J. Triswell.

Committee:

E. J. Bevan.	D. L. Howard.	Boverton Redwood.
H. G. Colman.	G. C. Jones.	Walter F. Reid.
J. N. Connah.	A. R. Ling.	F. Napier Sntton.
M. O. Forster.	B. E. R. Newlands.	Chas. Wightman.
Oscar Guttman.	Wm. Pearce.	

Hon. Local Secretary:

Julian L. Baker, 7, Addison Road, Bedford Park, W.

Manchester Section.

Chairman: G. H. Bailey.

Vice-Chairman: F. Scudder.

Committee:

J. Barnes.	B. Hart.	J. H. Lester.
J. Bürger.	W. B. Hart.	H. Porter.
W. H. Coleman.	R. S. Hutton.	F. Stenhouse.
J. Grossmann.	W. E. Kay.	W. Thomson.

Hon. Local Secretary:

Julius Hübner, Ash Villa, Cheadle Hulme, Cheshire.

Newcastle Section.

Chairman: H. Louis.

Vice-Chairman: J. T. Dunn.

Committee:

P. P. Bedson.	John Pattinson.	Harry Smith.
H. S. Collins.	W. W. Proctor.	A. Spiller.
Ellwood Holmes.	W. L. Rennoldson.	J. E. Stead.
N. H. Martin.	Geo. Sisson.	C. E. Stuart.

Hon. Local Secretary and Treasurer:

F. C. Garrett, Armstrong College, Newcastle-on-Tyne.

New England Section.

Chairman: Henry Howard.

COMMUNICATIONS

Authors of communications read before the Society, or of its Local Sections, are requested to take notice that Rule 43 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. This Bye-law renders papers liable to be selected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

SIXTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY, ROME, 1906.

The Sixth International Congress of Applied Chemistry will be held in Rome in April, 1906, during Easter week. All communications should be addressed to the President, Prof. E. Paternò, Via Panisperna, 89 Rome.

Changes of Address.

Keley, Dr. W. N., 1/o Puerto Rico; Food Inspection Laboratory, Appraisers' Stores, Philadelphia, Pa., U.S.A., Acting Chief.
 Ham, W. Popplewell, 1/o Rosecombe; Clothworkers' Research Laboratory, University, Leeds.
 ren, W., 1/o Birmingham; Journals c/o Thos. Nock, Oleander, Fresno Co., Cal., U.S.A., and subscriptions c/o H. C. Bowen, Chesterton, Bridgnorth, Salop.
 k, Prof. Friend E., 1/o State College, Pa.; Central University of Kentucky, Danville, Ky., U.S.A., Professor of Chemistry.
 man, W. H., 1/o Clayton; 78, Egerton Road, Withington, Manchester.
 ce, W. Ternent, 1/o Charlton; retain Journals.
 ing, G. A., 1/o Frankfurt; P.O. Box 3720, Johannesburg, Transvaal.

ST SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—8d. each, to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—1s. each, to the Secretary of the Society.

French.—1 fr. 25 c. each, to Belin et Cie., 58, Rue des Francs Bourgeois, Paris (3^e).

I.—PLANT, APPARATUS, AND MACHINERY.

ENGLISH PATENTS.

Filter-press; Alloy employed in the Manufacture of —
W. G. Cresthwaite. Eng. Pat. 20,842, 1904. N., page 973.

Filter-press; Impts. in — A. Howatson, Paris, and W. Babby, London. Eng. Pat. 21,644 Oct. 8, 1904.

Fig 1

Fig. 2

Fig 3

The filter is formed of the two vessels A and B, the latter being connected to the former by the ring C, as shown, so that the upper edge of B projects above the bottom of A and forms the annular gutter D. A grid of pipes, shown in fig 2, is placed on the bottom of the vessel

B; E is the outlet pipe, and passes through the bottom of B, and to it are connected the branch pipes E¹, close at their outer ends and perforated to receive the nozzle F. The latter, shown in fig. 3, are formed with flat top and several flat side faces, both the top and the side being perforated with fine holes G. The grid of pipes is cemented into the bottom of the tank B by bituminous cement. The grid may be replaced by a perforated bottom into which the nozzles are screwed. The water to be filtered enters by the pipe W and passes through the filtering medium O which may be of sand, broken flints, and away by the pipe E. The many fine perforations ensure a thorough use of the whole of the filter. When necessary to wash the filtering medium, the supply water is cut off and the tank drained out. Wash-water then admitted through E and, after percolating through the filtering medium, overflows into the gutter D, where it passes away by the pipe P. If desired, the surface of the filtering material may be agitated by the rake during the washing.—W. H. C.

Furnaces for Calcining and Burning Briquettes of and for similar Purposes. F. J. Bergendal, Hälsing, Sweden. Eng. Pat. 6388, March 25, 1905.

The invention relates to furnaces operated by gas which the burnt material heats the air passing into combustion chamber. In order to effect intimate mixture of the gas and air currents, and thereby assist combustion, a supply of air under pressure is introduced into the combustion chamber through openings disposed at an angle to the inlets for the gas and air currents. The air entering is derived from the enclosed space created by placing of a cap or cover over hot material withdrawn from the furnace, such heated air being forced along a connecting pipe by means of a fan.—E. S.

Separating Apparatus; Impts. in Centrifugal — Aktiebolaget Separator, Stockholm. Eng. Pat. 10,281, May 24, 1905. Under Int. Conv., May 27, 1904.

In centrifugal apparatus described in Eng. Pat. 3807 of 1904 (see Fr. Pat. 342,115 of 1904; this J., 1904, 895) in which the removal of the heavier particles of liquid is effected by means of scoop discs moving "planet-wise" along the inner periphery of the bowl, the following improvements are claimed. Inclined shields fast to either to the bowl or guide-disc are used to direct the heavy particles to the central outlet, and scrapers are provided to assist in removing the heavy particles from the inclined shields. The scoop-discs may have an inclined form to facilitate the sliding of the heavy particles to the inclined shields.—W. H. C.

Separating Apparatus; Impts. in Centrifugal — Aktiebolaget Separator, Stockholm. Eng. Pat. 10,281, May 24, 1905. Under Int. Conv., May 27, 1904.

The patent refers to improvements in centrifugal apparatus described in Eng. Pat. 3807 of 1904 (see Fr. Pat. 342,115 of 1904; this J., 1904, 895). Ring-shaped rolling surfaces are fixed within the bowl, above and below the scoop-discs, and the "naves" of the latter are prolonged so as to bear against the rolling surfaces. A cross-piece carried by the driving shaft embraces the upper ends of the "naves" of the scoop-discs, and keeps them in position.—W. H. C.

Evaporators with Heating and Evaporation in Separating Chambers or Compartments; Impts. in Vacuum — R. Sauerbrey, Stassfurt. Eng. Pat. 10,947, May 5, 1905.

To avoid the inconvenience caused by the deposition of solid matter on the sides of the vaporising chamber, the ascending pipe d, by which the liquid from the heating chamber b enters the vaporiser a, rises vertically through the descending pipe c, which leads to the separating chamber of tank c. The pipe d ends just above the surface of the liquid in a, and, as evaporation takes place at the surface, the solids are separated away from the sides of a, and

tend to form incrustations, but flow directly into c. plate f prevents any solid particles from being drawn in the pipe r leading to the exhausting apparatus.
—W. H. C.

UNITED STATES PATENT.

Filtering Apparatus. L. E. Beers, Aspen, Colo. U.S. Pat. 797,255, Aug. 15th, 1905.

A BOILER, condenser and tank are connected together by steam pipes, the boiler and tank also communicating by water pipes. The tank has the same water level as the boiler, so that when the level falls, a float in the tank is off the steam from the condenser and admits it to the tank, where it blows a whistle alarm, whilst at the same time, the valve admitting water to the tank is opened.
—W. H. C.

FRENCH PATENTS.

Filtering and Washing Apparatus. A. Hinze. Fr. Pat. 352,437, March 16, 1905. Under Int. Conv., March 17, 1904.

U.S. Pat. 793,133 of 1905; this J., 1905, 835.—T.F.B.

Apparatus for Treating — with Gases or Liquors. V. Defays. Fr. Pat. 352,719, March 25, 1905.

The apparatus which is similar to the well-known "washer" used in gas-works for ammonia recovery is shown in plan in the figure. A number of coils 3, of wire or gauze wound spirally on the shaft 2, are rotated in the rig 1, provided with inlet and outlet pipes for the gas 4 and 5, the liquid being circulated in the contrary direction, as in the ordinary washer scrubber. Claim is made for constructing the coils 3, of metallic gauze wound spirally, with the layers separated by a thin sheet of metal; several layers of gauze of different mesh, may be rolled together into a spiral. Further claim is made for a heating or cooling device, which consists in forming the rig chambers 6 and 7, on either side of the casing 1, the rig chambers being each divided by partitions 8 into several smaller ones which communicate with each other by

means of rows of tubes 11 passing between the separate coils of gauze 3. The cooling or heating agent enters at 9 and circulates in the direction indicated by the arrows, finally leaving by the outlet 10.—W. H. C.

Steam Trap for High and Low Pressures. G. Glöckler. Fr. Pat. 353,119, April 7, 1905.

THE valve of a steam trap is operated by the differential expansion of a nest of tubes of brass and iron or steel placed alternately in a casing. The iron tubes have flanges at one end on the inner, and at the other end on the outer side of the tube, and the ends of the brass tubes, which are threaded loosely on the iron ones, bear against these flanges. The steam trap is placed horizontally and so long as only water escapes from the valve, it runs away along a channel, placed underneath the tubes, without heating them. But when steam passes through the valve, it fills the casing and heats the tubes, causing them to expand and close the valve. When the apparatus is cold the valve is kept open by a spiral spring, and the steam-trap is provided with regulating and controlling screws, with a sieve to prevent foreign bodies such as grit getting into the valve and with a by-pass valve, by which steam may be blown through the apparatus to clean it.
—W. H. C.

Drying Oven; Rotary —. F. Balitrand. Fr. Pat. 353,129, April 7, 1905.

A NUMBER of tubes which may have plain or gilled outer surfaces are arranged longitudinally around the axis within a rotary drying cylinder. The tubes extend from the end of the cylinder where the hot gases from the furnace are introduced, and terminate at successively increasing distances from that end. The tubes not only serve to convey the hot and dry gas to every part of the interior of the drier, but also help to heat the material to be dried by radiation and conduction from their outer surface. Local condensation of moisture is avoided and the cost of the apparatus is, it is claimed, reduced, as owing to the rapid drying a much shorter cylinder can be used.—W.H.C.

II.—FUEL, GAS, AND LIGHT.

ENGLISH PATENTS.

Combustible Fluids for Power Purposes; Production of —. J. Clay, Liverpool, and S. Goodall, Birkdale, Lancashire. Eng. Pat. 11,971A, May 26, 1904.

PETROLEUM or mineral oil is vaporised by atomising it in a chamber under a partial vacuum, the vaporised portions being carried off along with the air, whilst the heavier portions are left behind in the chamber, to be drained off or otherwise removed.—C. S.

Hydrocarbon and other Liquid Fuels: Improved absorbent Non-Combustible Material for Burning — W. Galloway, Glasgow. Eng. Pat. 20,138, Sept. 19, 1904.

A NON-COMBUSTIBLE absorbent material, for use in the burning of oils, spirits, &c., is prepared by treating slag wool (silicate cotton) so as to eliminate metallic and gritty substances. For example, the slag wool is roasted and agitated, to cause glassy particles to fuse together; a small quantity of paraffin oil is sprinkled over the material, which is then allowed to cool; and it is then passed over screens of various meshes to remove the heavy and gritty particles.—H. B.

Gas from Pulverulent Fuel: Process of and Apparatus for Producing — G. Marconnet, Paris. Eng. Pat. 1587, Jan. 26, 1905. Under Int. Conv., Feb. 1, 1904. SEE Fr. Pat. 340,075 of 1904; this J., 1904, 745.—T.F.B.

Producer Gas Furnaces: Impts. in — P. Schmidt and A. Desgraz, Hanover, Germany. Eng. Pat. 3245, Feb. 16, 1905.

SEE Fr. Pat. 331,336 of 1905; this J., 1905, 838.—T.F.B.

UNITED STATES PATENTS.

Peat: Process of Treating — for the Production of Fuel and the Recovery of the By-Products. C. A. Sahlström. U.S. Pat. 796,019, Aug. 1, 1905. 111, page 962.

Gas Producer. W. B. Hughes, Wissahickon, Pa. U.S. Pat. 795,835, Aug. 1, 1905.

THE casing of the producer is divided horizontally, near the top, into two compartments. The upper portion, which is stationary, is provided with a fuel inlet for distributing the fuel in a circular path around the axis of rotation of the movable lower portion (body) of the casing and also carries, internally, an oscillating poker, which latter sweeps the fuel towards the axis of the body. The revolving body is attached, underneath, to an ash-hopper, partly conical and partly an open cylinder, so arranged as to support the fuel whilst leaving a free outlet for the ashes. The ashpit and sealing pit are also fixed to the revolving body, and are moved in unison with the same and with the ash-hopper.—C. S.

Gas from Peat: Apparatus for the Manufacture of Combustible — C. Whitfield, Northampton, England. U.S. Pat. 795,874, Aug. 1, 1905.

SEE Eng. Pat. 1738 of 1904; this J., 1905, 490.—C. S.

Gas Producer. E. Körting, Pegli, Italy.

U.S. Pat. 795,918, Aug. 1, 1905.

THE producer consists of a vertical down-draught shaft, with a central air-inlet and air-chamber in the upper part of same, and a bottom of considerable area, so that the fuel will move downward past the air chamber and leave a hollow space beneath the latter. The bottom of the air-chamber is perforated to supply air to the said hollow space, and the walls of the shaft, after sloping inwards at a sharp angle below the bottom of the air-chamber, are continued vertically downwards for some distance so as to form a secondary up-draught producing chamber of substantially uniform horizontal section. The gas outlets are in the part of the shaft below the main producing chamber, and a grate and closed ashpit are arranged at the bottom of the shaft. Means are provided for supplying air to the ashpit below the grate, and there is a channel leading from a point above the gas outlets down to the ashpit.—C. S.

Gas-Generating Plant. T. Fitzsimmons, Brooklyn, N.J. U.S. Pat. 796,632, Aug. 8, 1905.

TWO or more generators are connected at their tops by valve-controlled passage ways, with a receptacle common to all, whilst each generator is fitted at the bottom with a valve-controlled connection, leading to a source of vacuum, in order to reverse the draught of the generators

as desired. The generators are also fitted with valve-controlled air inlets at the top and bottom. The furnace which is arranged to burn alternately with an up-draught, is provided with an annular air-box underneath, which box has a number of upward passage ways located around the furnace. The latter has also a number of poker holes, situated just above the grate line, through which holes the said air passages pass and also a series of steam-injection pipes, whilst another series of steam pipes terminates at the grate line and beneath the bed of fuel, and a third series communicates with the top of the furnace. The passage ways from the air-box lead to the bottom of the fuel by means of a siphon, whereby air is heated before admission into the fuel.—C. S.

Gas: Process of Making — D. McDonald, Louisville, Ky. U.S. Pat. 796,670, Aug. 8, 1905.

A SUITABLE generator is charged with coke and with a superimposed layer of coal, the latter being of such height that the heat from the coke beneath can pass through the coal. The coke is raised to incandescence by a blast, which is passed through it but not through the coal, the latter being partly gasified by radiant heat from the coke. Steam is passed through the coke, and the resulting water-gas is enriched by passing it through the coal. The enriched gas is fixed by passing it through a superheater, and is mixed with the coal gas first given off. When the upper side of the coke is cooled, steam is passed down through the mass, the resulting water-gas being produced through the superheater and mixed with the gas obtained previously.—C. S.

Gas: Apparatus for Producing — J. Lühne, Albstadt, Chapelle, Germany. U.S. Pat. 796,917, Aug. 8, 1905.

THE apparatus consists of an exterior generator, and an interior generator, for producing heat and initial gasification; an interior generator, with means for maintaining it at a high temperature by the heat developed in the exterior generator, a receptacle, with perforated bottom, fitting the interior generator and containing a carburettor supplied with liquid fuel by suitable means; a dome surrounding the open end of the interior generator, a dome affixed to the cover of the outer generator, with sides extending downward far enough to be embedded in the charge maintained in the latter; and a separately removable structure enabling the receptacle already referred to, to be withdrawn for re-charging.—C. S.

Combustion: Device for Separating the Products of — W. Cline, Lancaster, Pa. U.S. Pat. 797,558, Aug. 8, 1905.

A SEPARATOR chest interposed between the heater and the chimney is provided with a removable bottom, sloping from the sides towards a discharge pipe in the centre. Sieve plates are secured to the removable part of the bottom at right angles to the flow of gas. Spraying nozzles are arranged in front of the sieves in a position to spray liquid against the sieves in a direction corresponding to the travel of the gas. One sprayer is placed below the last sieve and discharges obliquely into the space towards its inclined bottom and outlet.—R. L.

Combustion: Apparatus for Purifying Gases of — W. Cline, Lancaster, Pa. U.S. Pat. 797,661, Aug. 8, 1905.

A VERTICAL flue traversed by a rotating shaft, is interposed between the heater and the chimney. The gas is screened by sieve-plates spirally disposed on the shaft and revolving with it in frusto-conical enlargement of the flue. The shaft is provided with water-wheels between the sieve-plates; jets of liquid discharging against the periphery of the water-wheels from pipes penetrating the wall of the flue, cause the shaft to revolve and spray liquid upon the sieve-plates. A water-wheel at or near the base of the flue can be revolved by the liquid collecting there, and thus can drive a spiral suction fan located at the flue.—R. L.

FRENCH PATENTS.

for Generating Power; Method of Utilising Heavy Mineral —. Comp. Ind. des Pétroles. Fr. Pat. 52,267, March 10, 1905.

heavy oils are gasified in a heated metal cylinder, the resulting gas is passed through a condenser which is maintained at such a temperature that any heavy oil which may have escaped "dissociation" is condensed, leaving the lighter hydrocarbons uncondensed, the latter are removed for conveyance to an explosion or, whilst the condensed oils are either returned to the fier or utilised for heating the same.—C. S.

Gas Generator. W. Towns. Fr. Pat. 352,540, Jan. 12, 1905.

Eng. Pat. 29,170 of 1904; this J., 1905, 611.—T. F. B.

es; Electro-Catalytic Process for Obtaining Permanent —, with a Carburetting Substance. A. A. Evencio. Addition dated Feb. 16, 1905, to Fr. Pat. 350,528, Jan. 4, 1905 (this J., 1905, 721).

heated carburetting liquid is passed through a tube traversed by electric sparks or electrical discharges; or the liquid may be heated in presence of a catalytic it like porous charcoal, with or without spongy inum or the like; or the two operations may be combined, the result of the treatment being to gasify the liquid at a lower temperature than would ordinarily be necessary.—C. S.

luer Gas; Process and Apparatus for the Manufacture of —. F. Jahns. First Addition, dated March 1905, to Fr. Pat. 327,214 of Dec. 10, 1902 Under Int. Conv., Oct. 31, 1904. (See this J., 1904, 181.)

The production of weak gas, free from tar, from bituminous fuel, by means of two or more connected generators, pressure within the preliminary generator is to be increased as far as possible—for example, by providing a jet aspirator in the vertical flue connecting the preliminary generator with the one adjoining.—H. B.

luer; Suction for Weak Gas —, with Automatic Charging and Steam-Admission. V. E. Prétot. Fr. Pat. 353,000, March 20, 1905.

the top of the producer there rotates, on a vertical axis, a charging drum, having an opening on the top for admission of fuel from a hopper, and an opening in the bottom for letting the fuel fall through a corresponding opening in the cover-plate of the producer. The charging is therefore, regulated by the rotation or non-rotation of the drum. A spindle, passing axially through the drum and extending down into the fuel chamber, rotates with the drum but has a free vertical movement, and carries at its lower end a plate of helical form. The latter, according to its construction, always remains on the top of fuel in the producer. As the producer is being charged, therefore, the plate and its spindle rise continuously until a predetermined point is reached, when the upper end of the spindle disengages the driving gear, and the rotation of the charging drum ceases. The charging of the producer thus proceeds automatically according to the height of the fuel. The power for the driving gear may be obtained from a belt and driving shaft, or from a device connected to the explosion cylinder of the motor which is supplied with the gas from the producer. The casing of the steam inlet valve of the producer is connected by a pipe to the explosion cylinder of the motor in such a way that at each explosion the valve is raised from its seat and admits a certain amount of steam to the producer. The steam admission is thus varied automatically according to the consumption of gas.—H. B.

Gas Generator. J. Radcliffe. Fr. Pat. 352,812, March 28, 1905.

Eng. Pat. 7592 of 1904; this J., 1905, 490.—T. F. B.

Gas from very Light Combustibles, such as Straw, Hay, Bagasse, &c.; Generator for the Production of Mixed —. Cie. du Gaz H. Reche, and C. P. Bratasiano. Fr. Pat. 352,908, April 1, 1905.

THE generator into which the straw or other material is charged is of large cross-sectional area, so that the fuel may sink readily in spite of its low density. The incandescent, situated at one side at the foot of the generator, is provided with fire-bars having gutters on the upper surface. These gutters, in order to maintain a proper proportion of water to combustible, may be fed with water or hydrocarbon, according to the state of dryness or wetness of the fuel. Beneath the incandescent column of coke, through which the gas is led, a chamber of considerable size is provided, to favour the deposition of solid particles from the gas before it ascends through the coke. The hot gas, on leaving the coke, is led down a washing tower, in which it is caused to bubble through successive quantities of hot water.—H. B.

Gas Generator having no Fire Grate. Soc. Erhardt and Schmeier G.m.b.H. Fr. Pat. 352,938, April 3, 1905.

THE body of the generator, which is open at the bottom, rests in an ash-pan, filled with water, which serves as a hydraulic seal. The blast-pipe rises from the centre of the pan and is covered by a conical bell, which prevents the fuel and cinders from entering the pipe. The cinders, resting on the ash-pan, support the fuel, without the intervention of a fire-grate.—H. B.

Producers; Method and Apparatus for Keeping Constant the Temperature of Suction Gas —, having Varying Consumption of Gas. E. Capitaine. Fr. Pat. 353,985, April 6, 1905. Under Int. Conv., April 8, 1904.

To prevent the fall in temperature which occurs in a suction gas-producer when the rate of gas consumption decreases, a portion of the gas generated is led off from the gas main as required and utilised in maintaining the temperature. For example, it may be conducted to a series of burners surrounding the generator and there burned, the flames being directed against the generator to minimise its loss of heat by radiation; or it may be burned so as to heat the pipes conveying air and steam to the generator; or it may be led along with air into the lower part of the generator, and there burned. The valve through which the gas is led off from the main is regulated automatically by a governor on the gas engine which takes the gas supply.—H. B.

Gas; Process and Apparatus for Washing —, particularly for Removing Sulphuretted Hydrogen from Coal Gas. E. Ott. Fr. Pat. 352,565, March 18, 1905.

THE crude gas is scrubbed with concentrated aqueous ammonia (say, 30 per cent. strength), to remove the sulphuretted hydrogen, and is then washed with water in the usual way to free it from ammonia. The apparatus consists of a series of small superposed chambers, into each of which a downwardly-directed jet of strong ammonia solution is introduced under pressure and passes down a tube acting on the injector principle, whereby the crude gas is aspirated downwards along with the liquid, and is broken up into fine bubbles. The gas passes through each of the chambers in succession, separating from the liquid at the bottom of each and passing into the one below, whilst the used liquid is led off from each compartment to be used over again or submitted to a recovery process.—H. B.

Lamps, Electric; Impts. in Osmium-Filament Incandescent —. Soc. Française d'Incandescence par le Gaz (Système Auer). Fr. Pat. 352,751, March 27, 1905.

WITH the osmium of the filament there is mixed one or more of the reducible, highly infusible metals of groups VI. and VIII. of Mendeleef's periodic system. For example, a plastic paste formed of osmium, fine carbon and an agglutinant is mixed with molybdenum oxide, and after being extruded into filaments, the latter are dried, baked *in vacuo*, and heated highly by an electric current in a vacuum or an indifferent or reducing atmos-

phere. Whatever method is employed for producing the filament, the proportion of carbonaceous matter should be just sufficient, or rather less than sufficient, to reduce the oxide used. According to another method, a filament made entirely of the metal selected may be coated with osmium or a mixture of the latter with metals of the platinum group, and the filament thus coated is then raised to incandescence *in vacuo*, or in a suitable atmosphere, so that the metals become alloyed.—H. B.

Mantles; Process of Manufacture of Incandescence — Comp. Française de l'Acétylène Disson. Fr. Pat. 353,088, April 6, 1905.

The fabric to be used in the manufacture of incandescence bodies is made of felted or carded cloth, instead of the usual tissues knitted from threads.—H. B.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

Di-p-ditolylethane and the Dihydrides of 2,7,9,10-Tetramethylanthracene and 2,7-Dimethylanthracene; Constitution of Dissymmetric — J. Lavaux. Comptes rend., 1905, 141, 351–356.

By a critical examination of previous work by himself (this J., 1905, 884), Anschütz, (Ann., 235, 313) and Ador and Crafts (Ber., 10, 2173), the author proves that the ditolylethane, obtained by condensing *unsym. dichloroethane* with 2 mols. of toluene, has both its methyl groups in the *p*-position to the methylene group, and then shows that the dihydrotetramethylanthracene, obtained by condensing this ditolylethane with a further molecule of dichloroethane, is the 2,7,9,10-compound; whence it follows that the dihydrotetramethylanthracene of m.pt. 244° C. produced by condensing toluene with dichloromethane in presence of aluminium chloride, and also derived from the above tetramethyl compound by the loss of the methyl groups in the nine and 10 positions, is 2,7-dihydrotetramethylanthracene.—T. F. B.

Petroleum; Sulphur Compounds and Unsaturated Hydrocarbons in Canadian — C. F. Mabery and W. O. Quayle. Proc. Amer. Acad. Arts and Sc., 1905, 41, 89–113. (See also this J., 1894, 507.)

The following sulphur compounds were isolated:—

	B. pt. °C.	Sp. gr. at 20° C.	Refractive Index.	Molecular Refraction.
Heptyl-thiophane ..	158–160	0.8878	1.468	40.82
Octyl-thiophane ..	167–169	0.8929	1.4860	44.92
Iso-octyl-thiophane ..	183–185	0.8937	—	—
Nonyl-thiophane ..	193–195	0.8997	1.4746	49.50
Decyl-thiophane ..	207–209	0.9074	1.4766	53.60
Undecyl-thiophane ..	128–130	0.9147	1.480	58.53
50 mm.				
Quaddecyl-thiophane	266–268	0.9208	1.4892	71.61
Sexdecyl-thiophane	283–285	0.9222	1.4903	80.44
Octodecyl-thiophane	290–295	0.9235	1.4977	—

Oxidation products, as detailed below, were obtained by adding slowly to the above sulphur compounds one and a half times the calculated quantity of potassium permanganate dissolved in thirty times its own weight of water, and keeping the solution cold. The manganese oxide was separated by filtration, and the unoxidised sulphur compounds by steam distillation, the oxidation products being extracted from the residue by ether. The products were: impure hexyl-thiophanesulphone; heptyl-thiophanesulphone (sp. gr. at 20° C. 1.1138); octyl-thiophanesulphone (sp. gr. 1.1142); nonyl-thiophanesulphone (sp. gr. 1.1161); undecyl-thiophanesulphone (sp. gr. 1.1126); and dodecyl-thiophanesulphone (sp. gr. 1.1372).

It is considered that the structure of the thiophanes, $C_{12}H_{18}S$, will have to be referred to the methylene ring, though the precise formation of the ring, with regard to the number of contained carbon atoms, is still uncertain.

Small quantities of hexylene, heptylene, octylene and nonylene were obtained from distillates of the sludge from the sulphuric acid treatment in refining, the unsaturated hydrocarbons having been dissolved out of the acid without decomposition. The sludge oil was also found to contain sulphur-free oils, which are soluble in alcohol and resemble terpenes in smell; they have yet been identified.—C. S.

Peat; Process of Treating — for the Production of Fuel and the Recovery of the By-Products. C. A. S. ström, Ottawa. U.S. Pat. 796,019, Aug. 1, 1905.

PEAT is shredded and subjected to a continuously increasing pressure to extract a portion of the moisture; it is then disintegrated without destroying the fibre heated to completely dry it, and the fibre separated from the peat powder by screening. The peat powder is now heated to a gradually increasing temperature till the acetic acid, ammonia, and other non-combustible gases are driven off, then further heated to remove tarry matter and certain other combustible products, afterwards partially cooled by blowing steam through it, whereby water-gas is produced. The solid residue is mixed with sufficient of the tarry products to serve as binding it, and the previously obtained combustible gases are absorbed by bringing them into contact with the cooling mass. The product is finally compressed into briquettes.—T. F. B.

IV.—COLOURING MATTERS AND DYE STUFFS.

Dyestuffs; New Direct [Azo] — P. Barhier. Soc. Ind. Mulhouse, 1905, 153–154.

NEW azo dyestuff components, derived from diphenyls combined with the tetrazo-derivatives from benzene, the *p*-*p'*-diamino-phenyltolyls, tolidine, *p*-*p'*-diaminodixyls, dianisidine and all other diamines of the character. The new components are:—*o*- and *m*-anodiphenyl and their alkylated derivatives; *o*- and *m*-anodiphenylmono- and disulphonic acids and their alkylated derivatives; hydroxy- and dihydroxydiphenyls and their mono- and disulphonic acids; aminohydroxydiphenyls and their alkylated, arylated and sulphonated derivatives. The products vary in shade from red, through orange, yellow and blue to violet. They dye cotton directly and the colours are fast to acids. Compounds of similar shade and properties are obtained by combining the tetrazo compounds mentioned above, partly with the above-mentioned new components and partly with the components ordinarily used.

In a report on the preceding article, E. Noelting points out

it was known that di-*p*-dihydroxydiphenyl does not combine with diazo-compounds. The fact that hydroxy-1 dihydroxydiphenyls having the hydroxyl groups at other positions do combine is, though not unexpected, very interesting. Noelting does not believe that any of the dyestuffs mentioned are manufactured industrially. —E. F.

Dyestuffs; *New Hydrazinic* —. M. Prud'homme. Bull. Soc. Ind. Mulhouse, 1905, 155—156.

CESTA is diazotised, sodium bisulphite added, and the ole allowed to stand for 24 hours. The solution is then heated to 60° C., more hydrochloric acid added and the heating continued. A dyestuff of acid character is thus obtained dyeing wool in prune shades. If benzaldehyde be added immediately after the hydrochloric acid, another dyestuff of much bluer shade is obtained, also dyeing wool from an 1 bath. A similar product, though not quite so blue, is obtained if the benzaldehyde be replaced by acetone. The azo-compound from Safranin, treated with sodium sulphite and hydrochloric acid, yields a dyestuff giving net-red shades on wool. The leuco-compound obtained from diphenylcarbinol and sulphanilic acid, diazised and then treated similarly, gives a green very close to alkalis. *p*-Nitraniline gives a rather weak yellow, a very fine yellow being obtained in presence of benzaldehyde.

Noelting points out that the hydrazinosulphonates of acid character described in the preceding article, are very different in character to the basic dyestuffs obtained by the action of aldehydes and ketones on the basic dyes themselves, which have been described by Ziegler. —E. F.

Dyestuffs [*Oxazine Dyestuffs*] *Green* —, obtained by the condensation of Nitrosodimethylaniline with Polyhydroxylated Benzophenones. J. Eliasberg. Bull. Soc. Ind. Mulhouse, 1905, 157—158.

ROSODIMETHYLANILINE reacts with polyhydroxylated benzophenones, more especially with those derived from gallic acid, forming oxazine dyestuffs which dye in green shades on chrome-mordant. Amongst the benzophenone derivatives used were hexa- and penta-hydroxybenzophenone tetrahydroxynaphthylphenylketone. The method of preparation is the same as for Gallocyanine. The dyestuffs are only very slightly soluble in water, and for printing they must be used in the form of their sodium sulphate addition products.

In a report on the preceding article, C. de la Harpe states that he repeated Eliasberg's experiments and also prepared analogous dyestuffs, using trihydroxyphenylphenylketone (Alizarin Yellow C, B.A.S.F.) trihydroxybenzophenone (Alizarin Yellow A, B.A.S.F.) and tetrahydroxy-β-methyl-coumarin. The nitrosodimethylaniline was also replaced by nitrosodiethylaniline and by nitrosodiethylanilinesulphonic acid. In all cases the results were low and the dyestuffs poor in quality. The results do not seem to combine with phenols to form gallocyanines. —E. F.

Azo Dyestuffs and New Intermediate Products for use therein; *Manufacture of New* —. H. E. Newton, London. From Farbenfabriken vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 1675, Jan. 27, 1905.

THE new dyestuffs are obtained by combining diazo compounds with hydroxynaphthimidazoles or with hydroxynaphthoxazoles. The hydroxynaphthimidazoles can be prepared by the action of aldehydes, mixtures of aldehydes and ketones, acid anhydrides or acid chlorides on 1,2-naphthylenediamine-5-hydroxy-7-sulphonic acid. When employing acid anhydrides or acid chlorides the acyl derivatives first formed, must be heated with acids in order to close the ring, e.g.,

p-methyl-1,2-naphthimidazole-5-hydroxy-7-sulphonic acid

is prepared by first treating 1,2-naphthylenediamine-5-hydroxy-7-sulphonic acid with acetic anhydride and sufficient sodium carbonate to keep the solution neutral, and subsequently acidifying with hydrochloric acid and boiling. 1,2-Naphthylenediamine-5-hydroxy-7-sulphonic acid is prepared by reduction of the azo dyestuff obtained when *p*-nitraniline is combined in acid solution with 2,5,7-aminonaphtholsulphonic acid. Using *o*-, *m*- or *p*-nitrobenzylchloride in place of acetic anhydride in the above example, the corresponding *p*-nitrophenyl-1,2-naphthimidazole-5-hydroxy-7-sulphonic acids are obtained which on reduction yield respectively *o*-, *m*- and *p*-aminophenyl derivatives. The latter combine with diazo compounds. The resulting dyestuffs can be further diazotised on the fibre and developed to red or bluish red shades, which are fast to washing.

The hydroxynaphthoxazoles are prepared by the action of acid anhydrides or chlorides on 1-amino-2,5-dihydroxynaphthalene-7-sulphonic acid. The latter substance is prepared by reducing the diazo compound of 2,5,7-dihydroxynaphthalenesulphonic acid. (See also U.S. Pat. 792,600, 1905; this J., 1905, 796.)—H. L.

Anthraquinone Derivatives; *Manufacture of* —. H. E. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 3160, Feb. 15, 1905.

p-NITRO- α -HYDROXYANTHRAQUINONES are obtained by nitrating erythrohydroxyanthraquinone, chrysazin or anthraquinone in sulphuric acid solution in presence of boric acid. For example, 5 parts of crystallised boric acid are added to a solution of 10 parts of chrysazin in 200 parts of sulphuric acid of 66° B ϕ . The mixture is heated to 50° C. for two hours, cooled to 10–15° C., and a solution of 2 mols. of nitric acid in sulphuric acid added. After stirring for three hours the melt is poured into water, by which means the product, *p*-dinitrochrysazin is precipitated. 1,4-Nitrohydroxyanthraquinone is claimed as a new article of manufacture.—E. F.

Azo Colouring Matters; Manufacture of —. T. R. Shillito, London. From Aniline Colour and Extract Works formerly J. R. Geigy, of Basle, Switzerland. Eng. Pat. 2228, Feb. 4, 1905.

Diazo compounds of *o*-aminophenol-sulphonic acid, its homologues and substituted derivatives are combined with ethyl- α -naphthylamine. The dyestuffs produce red to violet shades on wool from an acid bath, turning to violet and blue shades fast to milling after treatment with bichromate. By treatment with copper salts the shades become violet to blue, especially pure blue shades being obtained from an aminophenol-sulphonic acid with the sulphonic group adjacent to the hydroxyl. The combinations of the following acids with ethyl- α -naphthylamine are described: —1,2-hydroxyaminobenzene-4-sulphonic acid, 4,5-hydroxyamino-toluene-3-sulphonic acid, 1,2-hydroxyamino-4-nitro-benzene-6-sulphonic acid, 1,2-hydroxyamino-6-nitro-benzene-4-sulphonic acid, 1,2-hydroxyamino-4-chloro-benzene-6-sulphonic acid, 1,2-hydroxyamino-4-acetamino-benzene-6-sulphonic acid, and 1,2-hydroxyamino-benzene-4,6-disulphonic acid. —H. L.

Dyestuffs; Manufacture of Chlorinated Indigo —. O. Imray, London. From Farb- u. vorm. Meister, Lucius und Brünig, Hoechst-on-Maine, Germany. Eng. Pat. 3182, Feb. 15, 1905.

CHLORINATED indigo dyestuffs are obtained by treating indigo or, by preference, Indigo-white with sulphuryl chloride. An indifferent liquid solvent may be used, but is not essential. Carriers such as iodine are not absolutely necessary, but may be used. For example, 27 parts of indigo are suspended in 200 volumes of carbon tetrachloride and 68 parts by weight of sulphuryl chloride are added. The whole is allowed to stand at the ordinary temperature until the sulphuryl chloride has disappeared, and the chlorinated product is isolated by filtering and distilling off the solvent. The chlorinated indigos thus obtained, dye in shades which are redder and clearer than those obtained with indigo, and similar to those produced by the corresponding bromo-derivatives. —E. F.

—PREPARING, BLEACHING, DYEING, RINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

Merising Industry; Studies on the —. F. J. G. Beltzer. *Monit. Scient.*, 1905, 19, 641—651.

This article, which is supplementary to a previous one (this J., 1904, 981), dealing with the actual merising process, discusses the utilisation of the spent caustic soda liquors. Those of a strength lower than 4° B. are used for scouring the cotton previous to merising, whilst those stronger than 4° B. are more profitably concentrated. Evaporators working on the Kestner principle are recommended. A description is given of typical evaporators and their working, and some results of actual working. An ideal merising establishment is also described. It is calculated that the average saving obtained by concentrating the spent liquors is 0.15 fr. kilo. of cotton merised.—T. F. B.

Chrome Mordant; Action of Sodium Silicate and of Sodium Hydroxide on —. C. Fabre. *Bull. Soc. Ind. Mulhouse*, 1905, 150—152.

The affinity of chromium oxide, when fixed on the fibre, for dyestuffs, is diminished by the action of sodium silicate increased by that of sodium hydroxide. At the same time sodium silicate turns the shade of the fabric dyed directly towards blue, whilst sodium hydroxide turns it to a purpure green. It is therefore possible to obtain an effect of semi-discharge by printing on to the chrome-morded fabric sodium silicate solution of 38° B. thickened with starch paste, steaming, souring, and then dyeing. The result is a bright design on a clearer ground, obtained by printing on to the chrome-mordanted fibre sodium hydroxide solution of 38° B. thickened with starch paste.

E. Aliston confirms the results of C. Fabre. The effect of the sodium hydroxide is not primarily due to any merising action. This is proved by the fact that by printing with sodium hydroxide solution of 38° B., steaming, then chroming and dyeing, the fabric is dyed almost evenly throughout.—E. F.

Dyestuffs; Action of Tannin on the Leuco-Derivatives of Aldehyde —. E. Justin-Mueller. *Bull. Soc. Ind. Mulhouse*, 1905, 90.

CO-DERIVATIVES of sulphide dyestuffs combine with tannin to form compounds insoluble in water, which are chemically stable when exposed to the air, and are decomposed by sodium hydroxide solution forming the original, easily oxidisable leuco-compound. Attempts to utilise tannin addition products for printing on cotton were partially successful.—E. F.

ENGLISH PATENTS.

Printing or Preparing Fibrous Stems or Straws, especially Flax, preparatory to Scutching; Process of —. G. J. Hunter and L. J. Moser, London, and T. Burrows, Birmingham. *Eng. Pat.* 17,775, Aug. 16, 1904.

Flax or other straw, either green or dried, is boiled two to three hours in a solution of alkali (e.g., a 2 per cent. sodium carbonate solution), with or without the addition of oil or soap; the bath is then allowed to cool and the flax steeped in it for a further four or five hours, when it is washed. If desired, it may now be treated with a dilute acid. The fibrous material is finally pressed or crushed, e.g., between rollers, and then dried, when it is ready for scutching.—T. F. B.

Yarns; Process for Improving —. M. Höfken, Jarmen-Rittershausen. *Eng. Pat.* 7140, April 4, 1905.

Yarn made from paper pulp is dipped for a short time into the finishing material (glue, dextrin, potato starch, &c., with oil, fat or soaps), and then immediately

treated under tension in a brushing machine. The bobbins of the latter are supplied with paraffin, wax, fat, or the like, for the purpose of providing the paper thread with a coating to render them smooth. The yarn, it is stated, is thus strengthened and protected from moisture.—W. H. C.

Dyeing of Textile Fibres or Fabrics (Including Black); Process of —. C. E. Wild, Lansdowne, U.S.A. *Eng. Pat.* 16,503, July 26, 1904.

SEE *Fr. Pat.* 345,251 of 1904; this J., 1905, 24.—T. F. B.

Dyeing and otherwise Treating with Liquids, Wool, Yarn and other Fibrous Material or the like; Apparatus for —. J. Rhodes, Shipley. *Eng. Pat.* 18,056, Aug. 20, 1904.

This invention relates to improvements in apparatus described in *Eng. Pat.* 25,823 of 1898 (this J., 1900, 14). The claim is for providing an equal distribution of the liquid by means of a circulating force pump and a system of pipes. The latter are so arranged that they can be turned aside so as to allow the material treated to be easily introduced and removed.—W. H. C.

Textile Fabrics and Materials; Perforated Beams or Cylinders on which — are treated with Liquids and Fluids. J. W. Kenworthy, Bradford, and J. D. Ward, Halifax. *Eng. Pat.* 20,665, Sept. 26, 1904.

A LAYER of "expanded sheet-metal" or other suitably reticulated material, wire gauze or wire netting, is interposed between the textile materials which are to be dyed, &c., and the perforated cylinders around which, to this end, they are wound, or, more commonly, between the latter and the layer of "lapping" upon which the materials are wrapped, the object being to effect uniform distribution through the materials of the dye, &c., liquors or the gases applied.—E. B.

Violet to Blue Shades on Wool; Production of Light, Fast —. T. R. Shillito, London. From Aniline Colour and Extract Works, formerly J. B. Geigy, Basle, Switzerland. *Eng. Pat.* 1367, Jan. 24, 1905.

THE process is similar to that described in U.S. Pat. 794,315 of 1905 (see this J., 1905, 841); in addition, the halogen derivatives of *o*-aminophenolsulphonic acid may be replaced by the following derivatives:—3.4.5-triaminocresolsulphonic acid; 4.2.6-nitroaminophenolsulphonic acid; 4-acetamino-2-aminophenol-6-sulphonic acid; 2.1.4.6-aminophenoldisulphonic acid. Derivatives of other *o*-aminophenolsulphonic acids may be employed, but the best results are obtained when the sulphonic acid group is *ortho* to the hydroxyl group.—T. F. B.

Dyeing Machines; Impts. in —. W. H. Fletcher, Passaic, U.S.A. *Eng. Pat.* 5244, March 13, 1905.

SEE U.S. Pat. 787,285 of 1905; this J., 1905, 544.—T. F. B.

Brewers' Wash, Sewage or Spent Dyes and the like; Evaporator for Evaporating the Liquid in —, the Evaporator being also applicable as a Smoke Washer. A. B. Lennox. *Eng. Pat.* 18,488, Aug. 26, 1904. XVIII.B., page 982.

Printing Machines [for Intermittent Printing] for Fabrics; Roller —. Mather and Platt, Ltd., and D. P. Smith, Salford. *Eng. Pat.* 21,509, Oct. 7, 1904.

THE printing, at predetermined distances apart, of cross borders or stripes upon textile tissues, is accomplished, according to this invention, with the aid of two pairs of endless chains, one pair bearing projections, the other, depressions, by the action of which upon the mandrels the two sets of printing rollers are brought into or thrown out of operation as required.

The bowl 1 (see figures) of the printing machine is provided at each end with an annular channel 2. Two endless chains 5 are led into the machine over wheels 6 above the first body- or ground-printing roller 7; these pass along the channels 2 and under guides attached to the side frames, and after leaving the last printing roller of the same set, are led out of the machine, returning to the

FIG. 1.

FIG. 2.

point of entrance over guide-pulleys 9 and through a tension apparatus 10, and cleaning arrangement 11. Two other, similar, endless chains 16 are led into the machine over wheels 17 above the last cross-border roller 18. These after leaving the first roller 19 of the same set, return over guide pulleys 20 and a tension arrangement 21. All four chains are driven by sprocket wheels 22, mounted on shafts 23, carrying toothed wheels 24, which gear with the main star-wheel of the printing machine, the gearing being so arranged that the four cam-chains move with the same speed as the periphery of the bowl.

The two chains 5 are provided with cams or projections 26, attached to their inner edges and fixed at predetermined distances apart from one another. At the same positions are also affixed protection plates, extending across the whole width of the bowl from one to the other of the chains. These plates, which are provided with screw adjustments 29, pass between the bowl and the printing rollers when the latter are lifted and effectually prevent any accidental smearing of the tissue with colour at the moment of the leaving or returning of the rollers. The chains 16 on the cross border side are provided with depressions 27 which correspond in length and in position on them with the projections 26 on the other chains 5. The chains 5 and 16 pass under the mandrels of the printing rollers and, therefore, when the projections on the cam chains 5 come under the mandrels the

printing rollers, which in this case print the ground pattern are pushed away from the tissue, and are held out of contact for the length of the projection, a corresponding blank space being left on the tissue. The chains 16 by means of their long projecting edges, normally hold the bowl the printing rollers upon which the cross-border pattern is engraved, and only allow them to drop in contact with the tissue and print when the depressions pass under the mandrels upon the side of the machine which they operate.

The pitch of the projections and depressions may be varied to suit the length of the pattern to be printed. Be it set, however, to correspond exactly on the two pairs chains and these chains being driven at the same speed the cross borders will in all cases be printed in correct register in the blanks left in the ground pattern.—E. B.

Discharging Pastes; Manufacture of —, for use in the Discharge of Dyed Textile Fabrics. J. Y. Johns. London. From Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. Eng. Pat. 12,147, June 10, 1905.

The discharging power of pastes containing a formaldehyde hydrosulphite compound or a formaldehyde-sulphoxyl compound is considerably augmented by the addition of metallic salts or oxides, or metals, which have a reducing action, or which can act as carriers of the reducing power of the discharging compound; metallic iron, iron sulphide and iron oxides are best suited for this purpose, though oxides or salts of tin, nickel, cobalt and mercury may be employed. A discharge paste may be prepared by mixing together four parts of sodium formaldehyde sulphoxylate, one part of finely divided iron powder, five parts of an alkaline thickening; this paste is prior to the material, which is then dried, steamed for at least 3½ minutes, washed and acidified.—T. F. B.

Finishing Machine for Textile and the like Fabrics. Improved —. L. Blanck, Reims. Eng. Pat. 8,417, April 17, 1905.

The claim is for a continuous finishing machine for moving and crushing straw and similar substances in textile fabrics. The fabric is passed successively between friction rollers and pricking cylinders, then under beaters and over perforated plates in connection with exhaust fans to remove the comminuted bodies, and finally between fluted cylinders and friction rollers. The machine is enclosed in a steam-heated casing, to prevent a sudden change of temperature and to ensure a thorough removal of the dust.—W. H. C.

UNITED STATES PATENTS.

Silk Threads; Device for the Manufacture of Artificial —. R. Linkmeyer, Brussels. U.S. Pat. 796,530, Aug. 8, 1905.

SEE FR. Pat. 352,528 of 1905; following these.—T. I.

Filaments from Viscose; Process of Manufacturing —. C. A. Ernst, Lansdowne, Pa. U.S. Pat. 798,531, Aug. 22, 1905.

The claims relate to a process of "setting" viscose filaments, by immersing them in a bath of alkali bicarbonate and a coagulating agent; a solution of sodium bicarbonate, ammonium bicarbonate, and ammonium sulphate is specified.—T. F. B.

Wool; Process of Separating Extractive and Adhesive Matters from —. A. P. Quackenboss, Providence, R.I., U.S.A. Assignor to Mary J. Bruns, Boston, Mass., U.S.A. U.S. Pat. 796,530, Aug. 8, 1905.

The wool is first treated with a solvent, the excess of which is then removed. It is next treated with an emulsifying agent, such as a solution in warm water of neutral soap, the resulting magma is expressed and the grease is recovered from the same, by first heating it and then refrigerating, in order to stratify the constituents.—E. B.

ching Apparatus; Continuous —. M. Muntadas Rovira, Barcelona, Spain. U.S. Pat. 796,345, Aug. 1, 1905.

Fr. Pat. 327,931 and Additions thereto; this 903, 948; 1904, 251 and 933.—E. B.

dant. G. M. Lawton, Worcester, Mass. U.S. Pat. 797,588, Aug. 15, 1905.

is made for a mordant for use in the finishing bath, consisting of a solution of sulphate, nitrate, and pyroto of iron.—T. F. B.

ng Apparatus. J. Marshall, Fall River, Mass. U.S.A. U.S. Pat. 796,668, Aug. 8, 1905.

Apparatus consists of two tiers of dye-vats, one above the other below, and a series of movable frames. The frames are automatically passed through the upper series of vats and then through the lower series, being while revolved at suitable intervals.—E. F.

ng Violet to Black; Process of —. V. Füssinger, Assignor to Farbwerke vorm. Meister, Lucius & Brüning, Höchst on the Maine, Germany. U.S. Pat. 796,715, Aug. 8, 1905.

ES are dyed shades varying from violet to greenish-dark blue and black by impregnating them with indophenylamine (or one of its derivatives), a phenolamine, and the necessary oxidising agent, drying, teaming or heating. Such shades are said to be fast to light, boiling water, soap, "soda," dilute acids, ether and one, and slightly soluble in boiling alcohol and acetic.—T. F. B.

sing Apparatus; Rotary —. [for Textiles]. N. Dubois, Philadelphia, Pa. U.S. Pat. 794,085, July 4, 1905.

MOVEMENTS in apparatus which forms the subject of U.S. Pat. 676,647 of 1901, are proposed. They consist in the provision of means for preventing materials contained in rotary, oxidising cylinders becoming thrown to one end of the latter, thus enabling oxidation of the substances with which the textile materials are saturated to be effected more rapidly than hitherto. To this end the concentrically disposed rails, which the cylinders revolve, are so arranged that after being supported in inwardly inclined positions at an angle of 5° – 8° . With the greater rate of motion of the cylinders which this arrangement permits, the oxidation takes place, it is stated, in $3\frac{1}{2}$ – $3\frac{3}{4}$ instead of in the 4 hours' time previously necessary. The claims relate to high and low speed gearing for rotating the cylinders at a constant, positive, and uniform or low speed, as required.—E. B.

FRENCH PATENTS.

Manufacture of Artificial —. P. Cazenenne. First Addition, dated Feb. 6, 1905, to Fr. Pat. 350,723, July 12, 1905.

The original patent (this J., 1905, 799) the filament, passing from the draw-plate, is unwound from the bobbins and exposed in hank form to an atmosphere of ammonia. According to the present modification, the treatment with ammonia is replaced by treatment with a solution of ammonium sulphide or hydrosulphide. This is effected out by exposing the thread over an open vessel filled with these substances in aqueous solution. Fumes of ammonium nitrate are formed, the thread becomes coated with a thin layer of sulphur, and at the same time contracts and becomes consolidated. This treatment restores the final brilliancy and strength of the filament, which is subsequently denitrated with ammonium hydroxide as in the original patent.—E. F.

[*Cuprammonium Process*]; *Apparatus for Manufacture of Artificial* —. R. Linkmeyer. Fr. Pat. 352,858, March 20, 1905.

Filaments issuing from the coagulating bath are conducted through a fork which unites them so as to form a thread. This thread then passes over an upper

roller, which is driven at suitable speed; the thread is delivered vertically downwards from the roller into a cylindrical recipient to which is imparted simultaneously a rotary and a to and fro motion. The thread is thus deposited in the cylindrical vessel in uniform layers, which cross each other in the form of loops, and which can easily be wound off at a later stage.—J. F. B.

Flax, Jute, and Similar Fibres; Process of Treating for the Purpose of Bleaching. G. de Keulelaere. Fr. Pat. 352,442, March 16, 1905. Under Int. Conv., May 28, 1904.

SEE Eng. Pat. 13,773 of 1904; this J., 1905, 616.—T. F. B.

Zinc [Tin] Chloride for Mordanting and Weighting Silk and other Textile Fibres; Method of Facilitating the Decomposition of Solutions of —. C. E. Carstanjen. First Addition, dated Jan. 31, 1905, to Fr. Pat. 344,782, July 12, 1904.

ACCORDING to the original patent (this J., 1904, 1212) sulphates, sulphites or thiosulphates of certain metals are added to baths of "zinc chloride" to increase the formation of zinc oxide on the fibres. The patentee states that in the whole original patent a clerical error occurred, and the word "zinc" should in every case be replaced by the word "tin."—E. F.

Alizarin-Red; Dyeing Cotton in the Form of Caps, Spools, &c., in —. Soc. dite Ateliers de Construction de Saint-Georges près Saint-Gall (Soc. en commandite Ludwig von Süsskind). Fr. Pat. 352,328, March 13, 1905.

SEE Eng. Pat. 13,484 of 1904; this J., 1905, 543. The formula of the strontium "bisaccharate" employed is given as " $C_{12}H_{22}O_{11}.SrO$."—E. B.

Dyeing under Pressure; Apparatus for —. L. Dètré. First Addition, dated March 27, 1905, to Fr. Pat. 347,809, Nov. 11, 1904.

CERTAIN relatively unimportant additions are made to the main patent (this J., 1905, 331) including a helical arrangement for measuring the rate of flow of the dyeliquor.—E. F.

Aldehydic Derivatives; Production of — and their Applications as Discharges. Badische Anilin und Soda Fabrik. First Addition, dated Feb. 11, 1905, to Fr. Pat. 350,607, Jan. 7, 1905. Under Int. Conv., Oct. 28, 1904.

If aldehydes and hydrosulphites are brought together in equimolecular proportions in presence of hydroxides of the alkali or alkaline-earth metals, compounds of the general formula $R.CH_2.SO_2M$ are formed with simultaneous production of an alkali sulphite. These compounds may be described as salts of aldehyde-sulphoxylic acids (see this J., 1905, 329, 330). The products reduce neutral solutions of indigo-carmin on warming, and acid solutions of the same compound in the cold. The aliphatic derivatives are usually very soluble in water, the aromatic derivatives being only slightly soluble. They are said to be very suitable for use in both white and coloured discharges, and also for printing colours in the form of their leuco-compounds.

Example.—To a concentrated solution of neutral or alkaline sodium hydrosulphite, 1 mol. of sodium hydroxide solution of 40° B. is added (per mol. of $Na_2S_2O_4$), and is followed by 1 mol. of 35 per cent. formaldehyde solution. The liquid becomes warm. The solution may be used in this condition, or it may be freed from sodium sulphate by concentrating and allowing the latter to crystallise out, or by precipitating the sulphite by adding alcohol. 1 gm. of the final product decolorises 1.4 to 1.5 grms. of indigo on warming.—E. F.

Sizing Apparatus for Harps, of Large Output. C. Vandamme. First Addition, dated Feb. 21, 1905, to Fr. Pat. 343,801 of June 8, 1904.

THE additions to the original patent (this J., 1904, 1027) consist mainly of removable brushes to remove size from

the guide-rollers with which the sizing-chamber is furnished, and also of a battery of heating-tubes and ventilators at the entrance of the same chamber in order to completely dry the size before the warp arrives at the first guide-rollers.—E. F.

VI.—COLOURING WOOD, PAPER, LEATHER, &c.

FRENCH PATENTS

Skins Dyeing — for gloves and other purposes. P. Sorcl. First Addition, dated Feb. 9, 1905, to Fr. Pat. 341,450, dated March 19, 1904.

THE skins, stained in a bath of a chromium compound, as described in the original patent (this J., 1904, 864), may be used for all purposes for which glace, suede, etc., skins are ordinarily used, such as articles of clothing, fancy goods, surgical bandages, &c., as they are washable and the colour retains its brilliancy on soaping or on treatment with hot or cold water.—E. F.

Dyeing Leather; Process of — R. Rieder. Second Addition, dated March 13, 1905, to Fr. Pat. 291,355, Aug. 1, 1899. Under Int. Conv., March 14, 1904.

THE object of the process is to stretch the skins in various directions during dyeing, in order to insure a more complete penetration of the fibre by the dye-liquor. For this purpose, the skins are hung on cross-bars, which are placed transversely between two parallel circular discs. These discs revolve in a box of corresponding shape, whilst dye-liquor is sprinkled on to the skins from jets in the centre of the box. An obstruction is placed in the bottom of the box, against which the hanging skins strike, and this causes the desired stretching. The box can also be lowered into a dye-vat, in which case the obstruction is unnecessary, its place being taken by the floor of the dye-vat.—E. F.

VII.—ACIDS, ALKALIS, AND SALTS.

Nitric Acid; Strength and Specific Gravity of — G. Lunge. Chem.-Zeit., 1905, 29, 933–934.

WINTERER (this J., 1905, 800) is in error in asserting that the nitric acid used by Lunge and Rey for their specific gravity determinations (see this J., 1891, 543) contained nitrous acid. All the details of the preparation are given in the original paper, and the purity of the acids is beyond question. The author has plotted in comparative curves the results of Kolb, of Lunge and Rey, of Veley and Manley. (see this J., 1903, 1227) and of Winterer; and the close agreement of the Lunge and Rey and the Veley and Manley curves affords very strong confirmation of the accuracy of both, and consequently very strong evidence of the incorrectness of Winterer's results. The recently published tables of Ferguson (this J., 1905, 781) also agree very closely with those of Lunge and Rey and of Veley and Manley.—J. T. D.

Sodium Hydrosulphite; Alteration and Preservation of Anhydrous — in Powder and in Aqueous Solution. A. L. Lumière and A. Seyewetz. Rev. Gén. des Mat. Col., 1905, 9, 250–255.

ANHYDROUS sodium hydrosulphite remains unoxidised indefinitely in dry air. It can be safely kept in well-stoppered vessels. In moist air, however it is rapidly oxidised. A solution of hydrosulphite in boiled distilled water is oxidised in absence of air, a 3 per cent. solution being completely oxidised in 16 days, a 10 per cent. solution in 11 days, and a 25 per cent. solution in three days. The decomposition is much more rapid in presence of air, particularly in the more dilute solutions. A number of substances are found to retard this oxidation of hydrosulphite solutions; trisodium phosphate is the most efficacious of those which do not destroy the property of reducing indigo in the cold. Trioxymethylene in

presence of sodium sulphite, acetaldehyde, benzaldehyde and hexamethylenetetramine are among the substances which preserve hydrosulphite solutions, but the reduction of such solutions on indigo is only evident at temperatures about 100 °C. The principal oxidation products of aqueous hydrosulphite solutions are sulphite and sulphate, with smaller quantities of thiosulphate and thionates.—T. F. B.

Chloroborates of Calcium; The — L. Ouvre. Comptes rend., 1905, 141, 351–354.

LE CHATELIER has found that molten calcium chloride dissolves boric anhydride and lime in certain proportions producing $B_2O_3 \cdot 3CaO \cdot CaCl_2$ (Comptes rend., 99, 2). Another chloroborate of calcium, $5B_2O_3 \cdot 3CaO \cdot CaCl_2$, obtained by melting together for a considerable time equal weights of boric anhydride and calcium chloride, allowing the melt to cool, and separating the insoluble crystals by treatment with water. The needle-shaped crystals thus obtained, give place to prismatic crystals the same composition if the quantity of chloride be increased to not more than five times the weight of anhydride. The same compound is also produced adding lime to the melt, in quantity less than 0.25 mol. of anhydride. By increasing the additions of to less than 0.5 mol. per molecule of anhydride, crystals of $3B_2O_3 \cdot 3CaO \cdot CaCl_2$ are obtained; this compound less stable towards water than the former; the compound is formed by heating one part of boric anhydride with eight parts of calcium chloride. By the same proportions of anhydride to lime (2:1) diminishing the amount of calcium chloride, a chloroborate, $B_2O_3 \cdot 2CaO$ is produced: it is obtained as product when up to 50 per cent. of an alkali chloride added to the above melt. By increasing the quantity of calcium chloride to above 5 mols., or by adding 0.5 to 3 mols. of lime for each mol. of boric anhydride, Le Chatelier's chloroborate results. If, on the other hand, the lime be increased to 3 mols. or more, and the calcium chloride be reduced to less than 5 mols., no chloroborate is formed, even in absence of alkali chloride, but prismatic crystals of tricalcium borate, $B_2O_3 \cdot 3CaO$.—T. F.

um Ferrocyanide; Process of Making — C. Petri, Buchsweiler, Germany. U.S. Pat. 798,208, Aug. 29, 1905.

U.S. Pat. 798,208 of 1904; this J., 1904, 714.—T. F. B.

Oxygen; Manufacture of — C. F. L. de la Haye, Acetylene Dissoins. First Addition, dated Feb. 11, 1905, to Fr. Pat. 332,998, May 15, 1903. (See this J., 1903, 1195.)

THE mixture of a chlorate with combustible matter described in the main patent, which, when placed in a capsule and heated, gives off a previously determined quantity of oxygen, is now modified by the use alternatively in such mixture, of a bromate or iodate; or of a more highly oxidised salt, such as a perchlorate, perchromate, or periodate, in place of the chlorate. —E. S.

Oxygen; Apparatus [Gas Generator] for the Production of —, by the action of a Liquid upon a suitable Compound. J. A. Ageron. Fr. Pat. 352,152, March 17, 1905.

THE apparatus in its simplest form includes an inverted bell-shaped vessel having within it, supported on its bottom, boxes, perforated in the sides, and charged with peroxide of sodium, or similar substance, to which water can be admitted in regulated quantity through an opening in the bottom of the vessel. A tube leads from the apex of the bell, to a wash-bottle, whence the gas passes to a suitable holder.—E. S.

Air; Apparatus to Liquefy —, in several Portions of Different Composition. Soc. l'Air Liquide (Soc. Anon. pour l'Etude et l'Exploit. des Procédés G. Claude). Fr. Pat. 352,856, March 30, 1905.

THE apparatus consists of two tubular systems, of which

the first, A, communicates with the lower collector B, and the upper collector C; whilst the second system DD communicates also with the upper collector C, and with the separate lower collector E. Both systems are plunged into liquid air or oxygen, and one of them is supplied with cold compressed air, through one (B for instance) of the lower collectors, which air is partially liquefied in the tube A, and the liquefied portion, rich in oxygen, falls into the collector B, whence it may be withdrawn as required. The residual air, now poorer in oxygen, passes into the collector C and thence into the tubular system D, in which it liquefies and falls into the collector E. Under certain conditions, the liquid collecting in E may be nearly pure nitrogen. (Compare Fr. Pat. 338,842 and 338,964, of 1903; this J., 1904, 1216 and 1028.) —E. S.

VIII.—GLASS, POTTERY, AND ENAMELS.

UNITED STATES PATENTS.

Glass-Tank. W. E. Beck, Assignor to the Toledo Glass Co., both of Toledo, O. U.S. Pat. 796,410, Aug. 8, 1905.

A STATIONARY continuous glass-tank or furnace is provided with a top which may be moved horizontally so as to expose different portions of the glass for gathering through a port in the said top.—A. G. L.

Glass-Melting Furnace. H. Hilde, Rosswein, Germany. U.S. Pat. 796,513, Aug. 8, 1905.

THE glass-melting furnace is provided with a projecting

portion (a), having an outlet (c) in its bottom, below which is a block (b) running on rails, adapted normally to keep the outlet closed. Flanged pipes (g, h) are provided to allow a cooling agent to circulate through the block, which is also fitted with a horizontal knife (f) on its top for cutting off the glass at the outward run of the block.—A. G. L.

Glass: Manufacture of Sheets of —. F. L. O. Wadsworth, Allegheny, Pa. U.S. Pat. 797,646, Aug. 22, 1905.

A GLASS sheet is made in one operation by forming a sheet between rolling surfaces on both sides of an intermediate mesh, supporting the rolled sheet in a vertical plane by its margin only, and then subjecting both surfaces of the sheet to the simultaneous action of figured pressing-surfaces.—A. G. L.

FRENCH PATENTS.

[Glass] *Blast-Furnace Slag; Manufacture of Objects from* —. A. F. le Chatelier. First Addition of 25 Feb., 1905, to Fr. Pat. 350,659, of 10 Jan., 1905. (See this J., 1905, 592.)

TO the white-hot slag other substances, such as silica, lime, alumina, magnesia, or other earths, or alkalis, are added so as to obtain a mass suitable for making opal or other glass. Thus, if from a slag of the composition: silica, 40 parts; lime, 40; alumina, 10; metallic oxides, 1; bottle glass is to be made, 90 parts of silica and 10 parts of a mixture of equal quantities of potassium and sodium carbonates are added. In certain cases, if much silica be added, it may be necessary to re-heat the mixture before working it.—A. G. L.

Silica Glass; Manufacture of —. J. F. Bottomley, R. S. Hutton, and A. Paget. Fr. Pat. 352,996, March 15, 1905. Under Int. Conv., May 9, 1904.

SEE Eng. Pat. 10,670 of 1904; this J., 1905, 673.—T.F.B.

Rock Crystal (Quartz); Process of Making Hollow Vessels and Receptacles by Moulding Molten —. W. Heraeus. Fr. Pat. 352,483, March 17, 1905.

SEE Eng. Pat. 4663 of 1905; this J., 1905, 498.—T.F.B.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Rock Powders; Effect of Water on —. A. S. Cushma. U.S. Dept. Agric., Bureau of Chem., Bull. No. 92, pp. 2.

THE author has studied the effect of grinding a number of powdered crystalline rocks with water. In every case a considerable increase in the binding power of the powder is noticed after such treatment. This appears to be due to a certain amount of hydrolytic decomposition taking place immediately the water comes in contact with the rock powder, analogous to some extent to the action of water on glass and cement. In most cases an alkali silicate passes into solution, whilst the particles of powder become coated with a film of gelatinous ("gummy" insoluble silicate, such as aluminium silicate. It is owing to this film being constantly removed by abrasion during the grinding, that the action of water is so much more noticeable if the powders are ground, than when they are simply allowed to stand, with water. At the same time it appears that these gelatinous films, like other coagulated colloids, which the author proposes to call "pectoids" possess the power of selectively absorbing substances present in the solution. Thus if the mixture of rock powder and water obtained after grinding, be treated with phenolphthalein, a pink colour will generally be obtained, due to the formation of potassium silica; but if the rock-powder be first filtered off, and the phenolphthalein be added to the filtrate, no colour is produced; also, if the mixture of rock powder and water coloured with phenolphthalein be allowed to settle, the supernatant liquid will become colourless, whilst the solid particles will be superficially coloured pink. The suggested explanation of these phenomena is that the alkali bases first formed are absorbed by the pectoids coating the solid particles. The bases thus absorbed cannot be removed by mere washing with water, but can be, at least partially, dissolved out by treatment with a solution of ammonium chloride.

It is also suggested that the action of water on rock powders may be greatly increased by the presence of certain electrolytes, and that the potash contained in rocks may be rendered available in some such way.—A. G. L.

Portland Cement; Injurious Action on — of Oils and Fats. Tonindustrie-Zeit., through Chem. Rev. Feb. Harz-Ind., 1905, 12, 194–195.

IN preliminary experiments to determine the truth of conflicting statements as to the effects of mineral oils on Portland cement, the sample of the pure substance and of mixtures of it with three parts of sand or limestone were left to set for four days in moist air, and then treated daily with as much "signal" oil as they could absorb. The first signs of cracks appeared in the mortars containing sand and powdered limestone after 2½ months, whilst in the case of pure Portland cement they did not appear until after five months. The samples in this condition could be crumbled readily in the hand. Experiments were then made to determine the influence of different fats and oils upon pure Portland cements and mortars prepared from them. In each case the samples were allowed to set for seven days in a moist atmosphere, and then left in contact with the different oils, and tested after one, three, six, and nine months. The oils or fats employed were lard, whale oil, castor oil, linseed oil, petroleum, and "signal" oil, and their action on cements prepared from limestone and clay, chalk and clay, and furnace slag and limestone respectively was examined.

It is remarkable that the mortars containing sand, in many cases, offered greater resistance than the pure cements. Lard was undoubtedly the most injurious of the oils and fats employed, and the effects

ed by the "signal" oil are attributed to the presence of animal oil. Whale oil and castor oil were relatively less, and linseed oil and petroleum had no appreciable effect.—C. A. M.

ENGLISH PATENTS.

d; Vulcanizing or Hardening, Preserving and treating — W. Powell, Allerton, Lancs. Eng. Pat. 17,736, Aug. 16, 1904.

Wood in the "green" state is immersed in a saccharine solution in which neutral or "alkaline salts" of lead, iron, tin, aluminium, mercury, arsenic, boric acid, etc., have been dissolved. The solution is gradually raised to the boiling point, by which treatment most of the material in the pores of the wood is expelled. The liquid is then allowed to cool to the ordinary temperature, and the wood is then doing impregnates the wood, which is finally dried in air, beginning at a temperature of about 80° F. and going to 200° F. or more. A suitable impregnating solution consists of a 25 per cent. solution of sugar, to which 1 per cent. of lead acetate is added.—A. G. L.

pat; Manufacture of — J. E. Castle, Queenborough, Kent. Eng. Pat. 22,056, Oct. 13, 1904.

The usual cement mixture about 2 per cent. of fine shavings of "Thames ballast" is added, a saving in the cost of burning the cement being thereby effected.—A. G. L.

s; Process for the Treatment of Blast-Furnace Slag Production of a Material similar to — and the e. H. Colloseus, Berlin, Germany. Eng. Pat. 286, July 5, 1905.

of lime is injected into melted blast-furnace slag, whereby a porous substance free from water, and possessing the properties of natural trass is obtained.—A. G. L.

UNITED STATES PATENTS.

or Tile; Process of Manufacturing — C. B. Ke, Carlton, Minn. U.S. Pat. 795,488, July 25, 1905.

D. sand or granulated or powdered slate or their equivalents mixed with a very small proportion of dry cement is then very slightly damped and subjected, in moulds, to a pressure of upwards of 5000 lb. per sq. in. The bricks formed are then stored in a moist atmosphere for a period of 36 hours.—A. G. L.

silicon; Process for Treating — to produce therefrom Refractory Articles such as Brick, and the Resulting Product. B. Seaboldt, Salt Lake City, Utah, Assignor to C. Thorne, Tacoma, Wash. U.S. Pat. 796,459, Aug. 8, 1905.

silicon (Eng. Pat. 3629, 1903, this J., 1903, 743) mixed with compounds containing alkaline and acid constituents, and the mass is raised to a temperature sufficient to crystallise the silicon, but sufficient to decompose the added compounds, after which the temperature is further raised to a point at which the liberated silicic acid and alkaline constituents behave as fluxes relatively to the silicon, whereby some of the latter is fluxed, and a strength is imparted to the mass without crystallising the silicon.—A. G. L.

or; Process for Making Artificial — W. P. Butler, Minneapolis, Minn. U.S. Pat. 797,553, Aug. 22, 1905. A mixture of plastic cement material composed of a mixture of sand with powdered talc, soap-stone, or any other material having the smooth, soapy, and slippery properties of soap-stone, is formed in or on a mould.—A. G. L.

or; Process of Manufacturing Artificial — J. H. Audt, Bonn, Germany. U.S. Pat. 797,624, Aug. 22, 1905.

Fr. Pat. 348,601 of 1904; this J., 1905, 499.—T. F. B.

or; Process of Burning — B. E. Eldred, Oswego, N.Y., Assignor to Eldred Process Co., New York, N.Y. U.S. Pat. 797,506, Aug. 25, 1905.

The cement is burnt in a rotatory kiln in two distinct

stages, the mixed cement materials first passing through a relatively cool zone, in which they are calcined without being sintered by the action of a slow burning flame composed of injected solid fuel and air diluted with products of combustion, which latter are blown in from the flue for this purpose by means of a fan; after which the calcined mixture is sintered in a zone in which local combustion is intensified by means of a transverse jet of air directed towards the material. Both stages of and the plant necessary for, the process are also separately claimed.—A. G. L.

FRENCH PATENTS.

Materials Refractory to Physical and Chemical Agencies, and Process of Manufacture of the Same. A. de Karschhoff. Fr. Pat. 350,016, June 21, 1904.

REFRACTORY and resistant materials, e.g., firebricks and parts of furnaces, are made from natural or artificial spinels, especially chromite and magnesium aluminate, by mixing the powdered spinel with a specially prepared syrup, to which an aqueous solution of boric acid and tar residues may be added, then moulding under pressure and burning. Artificial spinels are made by heating in proper proportions aluminium oxide and magnesium oxide (or other oxides) with a relatively small quantity of boric anhydride which dissolves the two oxides, a spinel being formed. As this last is insoluble in boric anhydride, it separates out, further quantities of the oxides dissolving until the whole mixture has been converted into the spinel. In order to eliminate the boric anhydride, which would lower the fusing point of the final refractory product, calcium, or, better, aluminium fluoride is added to the mixture and the temperature is raised, when the boric anhydride is volatilised. The syrup mentioned consists of a mixture of starch and its decomposition products (glucose, &c.), with aluminium and magnesium oxides and an aqueous solution of boric acid. It is obtained by mixing waste vegetable matter (pine and fir shavings, &c.) with magnesium and aluminium oxides, and digesting the mass systematically with caustic soda in autoclaves. The product obtained is removed from the liquid, purified by renewed treatment with fresh caustic soda solution and carbon bisulphide, followed by washing, and is then converted into the syrup by heating with a solution of boric acid.—A. G. L.

Wood; Preservation of — W. Hoettger.

Fr. Pat. 352,615, March 22, 1905.

Wood, especially wood destined for use in mines, is impregnated with a hot solution of a silico-fluoride, e.g., with a $\frac{1}{2}$ to 1 per cent. solution of sodium or zinc silico-fluoride. On cooling, the greater part of the salt crystallises out in the pores of the wood, preserving it and rendering it non-inflammable.—A. G. L.

Wood; Process and Apparatus for the Manufacture of Refractory and Non-inflammable — H. Salomon.

Fr. Pat. 352,960, April 4, 1905.

THE wood to be impregnated is placed in a closed vessel on a bed of silicious material, e.g., infusorial earth or pumice, capable of absorbing water. The vessel is then heated and evacuated until the wood is dried, when a cold solution of caustic soda is gradually admitted into the vessel, and the heating continued. The caustic soda acts on the silicates, decomposing them and forming sodium silicate, with which the wood becomes impregnated. Finally the wood is again dried by heat. For decorative purposes the silicious materials may be mixed with colouring agents, or else coloured minerals containing silicates, e.g., ochres, certain iron phosphates, &c., may be used, whereby the wood becomes coloured as well as fire-proof. The apparatus necessary for carrying out the process is also claimed.—A. G. L.

Wood; Liquid for the Impregnation of — K. H. Wolman. Fr. Pat. 353,181, April 10, 1905.

THE liquid consists of a solution of a metallic salt of a mineral acid to which is added a salt of a weak organic acid, e.g., acetic or formic acid. The base of the latter neutralises the mineral acid otherwise set free in the

wood, and thus prevents the injurious action of the mineral acid on the wood.—A. G. L.

Bricks or Agglomerates of Cork and Tanners' Bark. C. C. Girod. Fr. Pat. 353,071, April 6, 1905.

THE claim is for the manufacture of a briquette or agglomerate composed of a mixture of cork and tanners' bark. It is stated that although the latter is much cheaper than the former, the briquette composed of the mixture is quite as useful as one made wholly of cork.—W. H. C.

Kühn, H. de l'Hygiène et de l'Art, for Burning Lime, Dolomite, and Analogous Materials. E. Schmatolla. Fr. Pat. 352,549, Feb. 17, 1905.

Plaster; Manufacture of Hardened —. O. de Werri. Fr. Pat. 353,242, April 12, 1905.

THE natural stone is powdered and the fine powder removed by levigation to moulds, in which it is dried, after which it is burnt as usual.—A. G. L.

Cement; Manufacture of —. J. H. Blin de Saint-Arnaud and J. Palais. Fr. Pat. 349,995, June 16, 1904.

BOTH cement materials and fuel for burning (coal, coke, &c.) are finely powdered and mixed together, without the addition of pitch, tar, &c. The mixture is moulded into briquettes, which are burnt as usual.

—A. G. L.

X.—METALLURGY.

Wrought Iron; Note on the Crystallisation of —. J. O. Arnold. Engineer, 1905, 100, 158.

SORBY in 1863 put forward the view that the polyhedral and rounded figures presented by wrought iron under the microscope were due to the interference of cubic and octahedral crystals. Direct evidence of cleavages parallel to the faces of the cube has, however, been wanting up to the present. The author has recently examined the end of a wrought-iron bolt which had broken after being in use for thirty years. The metal contained:—combined carbon, 0.047; silicon, 0.157; manganese, 0.006; sulphur, 0.020; and phosphorus, 0.350 per cent.; and was thus a very inferior wrought iron, the greater portion of the phosphorus not being contained in the involved slag, but in combination with the iron. On examining the fracture under the microscope, it was observed that one of the crystals of iron had broken at right angles to the axis of the bolt. When the fracture was cut off in the lathe and mounted for examination, the fractured face of this crystal was exactly at right angles to the axis of the microscope, and it was seen that the crystal exhibited perfect cleavages parallel with the faces of the cube. A micro-photograph of the crystal is given in the original.—A. S.

Iron and Steel; Influence of Nitrogen on —. H. Branne. Bull. Soc. d'Encour., 1905, 107, Rev. de Metall., 197—502.

DURING the past 20 years frequent cases of abnormal brittleness of iron and steel, especially in the case of metals manufactured by the basic process, have been met with, which have been proved, by chemical analysis, not to be due to the presence in the metal of excessive quantities of phosphorus, sulphur, or other elements of which the injurious action is known. The author's experiments lead him to the conclusion that this abnormal brittleness is due to the presence of nitrogen, fixed by the iron in different stages of its manufacture. The nitrogen is combined exclusively with the pure iron or ferric nitride produced, in the case of annealed metal, forms

a solid solution with the ferrite, lowering the solidification point of the latter, and also its solvent power for iron carbide; in the case of chilled steel, the nitride forms a solid solution with the martensite. Samples of iron steel of good quality were heated in ammonia at 800° for a more or less prolonged period, and then annealed in sand; the annealed metal was analysed, and its tenacity and elongation determined. The first experiments were made with a soft iron containing carbon, 0.06; silicon, 0.01; manganese, 0.06; sulphur, 0.005; and phosphorus, 0.05 per cent. It was found that the tenacity gradually increased as nitrogen was introduced into the iron, while the elongation decreased gradually until the proper introduction reached 0.07—0.08 per cent., when the metal became brittle, and with a further increase of nitrogen the elongation fell rapidly almost to zero. Micrographic examination showed that a change of structure occurred when the proportion of nitrogen introduced into the metal reached 0.07—0.08 per cent. This critical proportion of nitrogen (0.07 per cent.) is rarely met with in industrial products, but in very soft irons, especially in Lancashire iron, lower proportions of nitrogen are capable of rendering the metal harder and more brittle. Experiments with steels gave somewhat similar results, the critical proportions of nitrogen being 0.030—0.035 per cent. for steel containing 1.15 per cent. of carbon, 0.040—0.045 per cent. for steel containing 0.5 per cent. of carbon, 0.05—0.06 per cent. for steel containing 0.2 per cent. of carbon.—A. S.

Copper-Tin Alloys; Tensile Strength of —. E. Shepherd and G. B. Upton. J. of Phys. Chem., 1905, 9, 441—476. Chem. Centr., 1905, 2, 538. (See this J., 1896, 810; 1901, 814; 1905, 241.)

THE authors find that the tensile strength of copper alloys containing the pure α -crystals rich in tin is much affected by heat treatment. Bronzes containing 74.87 per cent. of copper become much stronger if they are heated above 510° C.; by long-continued heating the tensile strength is diminished, but the ductility is increased. The alloy containing 78.81 per cent. of copper has the maximum tensile strength; it consists of a mixture of α - and β -crystals. It is possible to prepare, on the one hand, a cast bronze with a maximum tensile strength of 60,000 lb. per sq. in., and an extension of 1.5 per cent., and, on the other, a bronze with a tensile strength of 45,000 lb. per sq. in., and an extension of 39 per cent.—A.

Aluminium-Zinc Alloys. E. S. Shepherd. J. of Phys. Chem., 1905, 9, 501—512. Chem. Centr., 1905, 2, 537—538.

MANY alloys of aluminium and zinc expand on solidification and should therefore give good castings, and since the two metals occupy positions near one another in the potential series, the alloys should not be very susceptible to atmospheric influences. The author determined the sp. gr. of a number of different alloys. The curve representing the specific volumes of the alloys consists of two branches slightly inclined to one another, and intersecting near the point corresponding to the alloy containing equal proportions of the two metals. The two phases probably consist of solid solutions. The solidified alloys are stable, their sp. gr. not being appreciably altered by heating for a week in boiling naphthalene. Alloys containing more than 50 per cent. of aluminium solidify completely above the eutectic point (381° C.). Microscopic examination showed that alloys containing more than 60 per cent. of aluminium are homogeneous, in the alloy containing 40 per cent. of aluminium, however, two phases can be distinctly recognised, one of which is the eutectic, containing 5 per cent. of aluminium. It is capable of taking up 4 per cent. of aluminium to form a solid solution; aluminium, on the other hand, will dissolve 50 per cent. of zinc.—A. S.

Magnesium; Alloys of — with Tin and Lead. N. S. Kurmakov and N. J. Stepanow. Z. anorg. Chem., 1905, 46, 177—192.

THE authors made melting-point determinations and micrographic examination of the alloys of magnesium

tin and with lead. The results of the melting-point determinations are shown in the accompanying diagram. In each case one compound is formed, of the type Mg_2N , corresponding to the points C and M. The portions A and D E of the curve A B C D E correspond to the crystallisation of tin and magnesium respectively; and in like manner the parts K L and N E of the curve A B C D E correspond to the crystallisation of lead and magnesium. The compound Mg_2Sn , dimagnesium stannide, is decomposed on exposure to moist air, yielding a black powder consisting of a mixture of metallic tin and hydrated magnesia. Magnesium-tin alloys are brittle; those containing a high proportion of dimagnesium stannide can be easily pulverised. Dimagnesium plumbide, Mg_2Pb , is more readily decomposed by moist air than the corresponding tin compound. (See also this J., 1905, 279.)—A. S.

Iron in Steel: Rapid Process for the Determination of —. H. Rubricius. XXIII., page 988.

Alloys: Flow of —. A. von Obermayer, G. Tannemann, N. Werigin, and J. Lewkojew. XXIV., page 988.

ENGLISH PATENTS.

Alloy employed in the Manufacture of Firebars. W. G. Rothwaite, Leeds. Eng. Pat. 20,842, Sept. 28, 1904.

The alloy is obtained by adding aluminium to molten pig iron, and then steel borings; the proportions used being preferably 100 parts of pig iron to 1 part of aluminium and 5 parts of steel, all by weight. The alloy when needed may be cast into firebars in the usual way.—E. S.

Refractory Plates: Manufacture and Treatment of Compound —. J. Bedford, Sheffield. Eng. Pat. 3739, Feb. 23, 1905.

A compound plate is formed by pouring into a mould successive layers of molten steel, each new layer being poured whilst the preceding one is still in a viscous condition. The layer forming the face of the plate is given its full content of carbon, i.e., 0.6 to 0.8 per cent., from the outside; the layers forming the back and middle of the plate will have on average not more than 0.35 per cent. of carbon. The plate is rolled and machined as usual, after which the face is raised to a temperature depending upon its condition, the back and middle being kept as cool as possible. The hot face is then freed from dirt as far as

possible, and cooled rapidly by means of a number of jets of compressed air, which issue from a perforated plate placed parallel to the armour plate, and forming the delivery end of an air box. The compressed air may be passed through a refrigerator before being supplied to this box. It is claimed that a glass-hard skin free from porosity can be obtained in this way. —A. G. L.

Mixing or Circulating Materials in a Liquid or Semi-Liquid State [Treating Gold bearing sand or slimes with Cyanide Solution]: Impts. in Apparatus for —. The Komata Reefs Gold Mining Co., Ltd., London. From F. C. Brown, Komata, New Zealand. Eng. Pat. 18,922, Sept. 1, 1904.

The upright cylindrical tank A has the pipe B fixed

concentrically within it, the pipe B terminates short of the top and conical bottom of the tank A. The material to be mixed is placed in the annular space between A and B, and the liquid or washing water is admitted to the annular space by the pipe C, and to the central pipe B by the pipe D.

Compressed air admitted to the bottom of the central pipe B by the pipe F, forces the material up the central pipe, to the top, where it overflows and descends through the annular space. In this way a continuous circulation takes place, which promotes a thorough admixture of the liquid and solid materials. When the mixture is complete, the liquid is drawn off after settling and the solids flushed out of E or A².—W. H. C.

Gold Extraction from Slimes, Tailings or the like. Improved apparatus for —. O. W. Ellis and F. S. Highton, Lincoln. Eng. Pat. 19,653, Sept. 12, 1904.

The ore-pulp is made to pass through a cone-shaped revolving cylinder, lined with detachable, amalgamated copper plates. The ore in passing over the amalgamated copper plates, leaves the gold as an amalgam thereon, and the latter is treated in the usual manner for recovering the gold.—J. H. C.

Ore-slimes, Treatment of —. P. J. Ogle, H. L. Sulman, and H. F. K. Picard, London. Eng. Pat. 20,300, Sept. 20, 1904.

The water is removed in a continuous vacuum filtering apparatus, the residual water being displaced by solvent liquor, the slimes are then agitated with the solvent in a vessel having an internal rotating spiral flange and a series of agitating projections working between the turns of the flange; finally the slimes are again filtered and the residual solvent is displaced by water. "Spitzkasten" are used when necessary to remove coarse particles.

Ore and Ore-ore, Briquetting Fresh — C. Reauke, Bredelar, Westphalia. Eng. Pat. 19,164, Sept. 9, 1904.

"MERZEL," consisting of limestone containing a high percentage of carbonate of lime finely ground with small additions of magnesia and good Portland cement, is intimately mixed with about six times its weight of the friable ore or ore-waste, and moulded into briquettes under high pressure. — J. H. C.

Furnaces for Calcining and Baking Briquettes of Ore and for Similar Purposes — F. J. Bergendal. Eng. Pat. 6388, 1905. — L., page 958.

Metals; Crucibles for Melting and Casting — W. Sommer, Paris. Eng. Pat. 11,119, July 8, 1905.

The crucibles are formed with a partition provided with flanges or collars, the upper one being designed to prevent the overflow of the metal at the moment of casting, and the lower one to facilitate the discharge of the metal and retain the crust of dross or other floating impurity. — J. H. C.

UNITED STATES PATENTS.

Ore-Roasting, Process of — J. A. Anker, J. H. Watson, and Pierce Evans, Los Angeles, Cal. U.S. Pat. 789,952, May 16, 1905.

The finely-divided ore is intermittently dropped in a thin stream or veil down a vertical tortuous chamber by stages, while pulsating flames, preferably produced by oil-burners, are forced against or through the streams of falling ore. Air blasts are employed for this purpose when necessary. — J. H. C.

Furnace; Roasting — F. Kleperko, New York. U.S. Pat. 793,939, July 4, 1905.

The invention, which may be applied to the McDougall or any similar furnace, consists of a rubble-arm rotating about a fixed axis, and provided with a series of rakes, the depths of which increase as they approach the central fixed axis referred to. — J. H. C.

Furnace; Ore-Roasting — H. C. Holthoff, Milwaukee, Wis., Assignor to Power and Mining Machinery Co., Cudahy, Wis. U.S. Pat. 797,003, Aug. 15, 1905.

An annular roasting chamber, having a rotary floor or hearth, surrounds a central combustion chamber, and is provided with means for discharging the roasted ore on to a stationary annular cooling hearth beneath it. Stationary stirrers having tubular arms pass through the roof of the roasting chamber, and are provided at the lower ends with inclined blades, capable of vertical and annular adjustment, which are placed across the hearth in series, with arrangements for a flow of water through the arms. Rotary stirrers move the ore across the cooling hearth, in an opposite direction to the movement of the ore in the hearth above. An annular wind trunk has intake openings around the inner sides of the cooling floor, a blower connected with which delivers the air thus heated by passage over the cooling ore, into a trunk connected by pipes located in the wall of the combustion chamber, into the roasting chamber around its inner side. — E. S.

Furnace; Ore Roasting — C. E. Keating, Assignor to B. S. Williams, both of East Chicago, Ind. U.S. Pat. 797,584, Aug. 22, 1905.

The turner is of the horizontal type, and has a relatively long hearth, having a track along each side, wheels riding

on which, support a shaft extending across the hearth. Stirring devices with "radially disposed arms, curved in radial direction," are rigidly mounted on the shaft; the shaft is moved along the hearth, the stirring devices rotate, the arms passing endwise into the mass of material, and lifting it edgewise therefrom, thus prevent the formation of a crust on the surface. Alternately with the rotating stirring devices are relatively fixed devices on the shaft, which serves to turn the mate into longitudinal furrows. — E. S.

Furnace for Roasting Ores — W. T. Rushton, London. U.S. Pat. 797,915, Aug. 22, 1905.

SEE Eng. Pat. 26,782 of 1902; this J., 1903, 1353. — T. F.

Slime Separating Apparatus — E. L. Godbe, Salt Lake City, Utah. U.S. Pat. 793,720, July 4, 1905.

THE slimes are run into a tank, within which a drum shaped filter revolves. A partial vacuum is produced within the drum which causes the slime to adhere closely to the filtering surface. This is sprayed first, with cyanide solution, then with water, and finally removed by brushing and scraping. But whilst considered preferable to employ this spraying, the invention is not limited to as it may be omitted, and the slimes, &c., may be removed without spraying. — J. H. C.

Slimes in Ore Reduction; Apparatus for Treating — G. A. Duncanson, Deadwood, S.D. U.S. Pat. 796, Aug. 8, 1905.

IN a vertical tank, the width of which is small relative to its length and height, a filtering cell similarly proportioned is suspended, there being but little space on opposite sides. Suction pipes enter from the top of the cell, of which the open ends terminate near the bottom, whereby the liquor supplied to the cell is sucked through the filtering walls, to be discharged from the bottom of the tank. Pipes extend along the sides of the filtering cell to the upper end, having numerous apertures through which flushing-jets are discharged inwards and downwards against the lateral walls of the cell. — E. S.

Ore-Treating and Filtering Apparatus — T. D. Jones, Denver, Colo. U.S. Pat. 795,774, July 25, 1905.

A BARREL is mounted on trunnions in a frame which is journaled at its extremities so as to allow of the barrel being rotated. At one end of the barrel there is a connection with a detachable section by means of flanges, between which flanges there are placed lead-covered plates. Perforated coils filled with filtering material are inserted between these plates, below which is fitted a valve attached to a valved outlet for the filtered liquid. An arrangement is provided for the purpose of subjecting the contents of the barrel to pressure. — A. G. L.

Ores; Apparatus for Treating Refractory — J. Loe, Baltimore, Md. U.S. Pat. 796,585, Aug. 8, 1905.

AN elevated furnace chamber, adapted for roasting ores by flames impinging from above, and having means for supplying to the ore an "alkaline cooling reagent," has a circular opening in its lower part, to which a boiler is mounted on a carriage movable on a trackway, and supplied with means for rotating and for raising and lowering, is adjusted. Within the chamber a series of burners are arranged in rows, having their orifices directed downwards to subject the ores to an oxidising flame. Placed between the rows of burners is an elongated horizontal liquid fuel distributor, having a series of discharge openings in its bottom, into which plugs, mounted on a movable block, fit in such a manner as to control the flow of mechanism for effecting which control is described. — S.

Ores [of Precious Metals]; Process and Machine [Mechanical] of Treating — J. R. Parks, Spokane, W. U.S. Pats. 796,753 and 796,754, Aug. 8, 1905.

A SLIME is prepared of the powdered ore, from which the coarse particles, unsuitable for the cyanide treatment, are removed. The coarser particles in the slimes are separated by ground, and added to the slime, which is allowed to settle, and the pulp remaining after running off the water is

ced with potassium cyanide solution, salt and lime pulp thus prepared is agitated by paddles between insulated amalgamated metal plate connected to the active pole of a source of electricity, above which plate a interval forming a chamber for the pulp) is a semi-circular stable annular metal discs, independently movable, and connected to the positive pole. Air is admitted under pressure to the compost. Insulation of the active metal faces from the containing metal shell of the apparatus obtained by layers of asphalt. —E. S.

FRENCH PATENTS.

d; Process of Reduction applied to the Manufacture of — J. de Moya. First Addition, dated Jan. 21, 1905, to Fr. Pat. 349,233, March 14, 1904. (This J., 1905, 677.)

THE preliminary process consists in adding to the molten metal in the converter, sodium chloride, or a mixture of sodium chloride with one of the substances named for reduction in the main patent, followed by the addition of benaceous material done up in packets of definite weight and content, to the metal as it flows into the ladles, the addition being made to the packets before the latter are filled.—E. S.

m and Steel; Manufacture of — J. J. Hudson. Fr. Pat. 352,400, March 14, 1905.

SEE U.S. Pat. 785,002 of 1905; this J., 1905, 336.—T. F. B.

st Iron, Steel and Special Qualities thereof; Process and Apparatus for Manufacturing — T. Levor. Fr. Pat. 352,778, March 17, 1905.

THE object of the invention is to make additions to molten cast iron, of soft or wrought iron, solid castings, oxidisers, or decarburisers, &c., during considerable increase of the heat of the bath, so that a temperature of 300° C. or more is obtained, whilst the mixture is being effected, whereby great improvement in the quality of the product is stated to result. The apparatus consists essentially of a pair of chambers, each closed at the top by a removable cover, mounted as a single structure of refractory material, on hollow trunnions through which air blasts are forced into a specially heated pipe circling the furnace and thence into and through a series of pockets containing liquid fuel so as to impinge on all sides upon the contained charge with the pul-

verised spray of the liquid combustion fuel. The two chambers communicate by means of a duct through which the flames from one chamber pass into the next, issuing from the top of the latter, the cover of which is removed at this stage of the process. Towards the process, molten cast iron is run into the first of the previously heated chambers, and when that chamber is highly heated, and the second chamber is also highly heated in the manner described, iron turnings, scrap, or the like are charged into the latter, and when molten, the metal is forced to flow into the first chamber through the connecting passage by tilting the furnace. —E. S.

Ores, Mixed, containing Gold and Antimony; Treating — H. L. Herrenschildt. Fr. Pat. 349,980, June 11, 1904.

THE ore, according to one process, is placed in an autoclave with substances capable of giving by reaction in presence of water on boiling under pressure, sodium sulphide or calcium sulphide. Or, the ore is boiled in the open with the same reagent, with or without previous roasting. If, however, the ore is roasted, it may be treated either with sodium sulphide or with sodium hydroxide. The antimonial solution obtained, may be precipitated by sulphurous acid to recover the antimony, and the gold in the ore thus purified is recovered by cyaniding or other suitable method. —E. S.

Liquid from Solid Matters; Apparatus for Separating — The Cyanide Vacuum Filter Co., Limited. Fr. Pat. 352,447, March 16, 1905.

SEE Eng. Pat. 15,776 of 1904; this J., 1905, 893.—E. S.

Zinc; Precipitating — from Liquids containing it. C. H. T. Havemann. Fr. Pat. 349,957, June 1, 1904.

ZINC is precipitated from its solutions as hydroxide by a solution of calcium saccharate, as shown by the equation:

FROM the solution of sugar remaining after separation of the precipitate, calcium saccharate is reproduced by addition of lime.—E. S.

Zinc; Precipitating — from Liquids containing it. C. H. T. Havemann. First Addition, dated Aug. 17, 1904, to Fr. Pat. 349,957, June 1, 1904. (See previous abstract.)

IT is now directed to wash the precipitate, consisting of zinc hydroxide and calcium sulphate, with a solution of sodium chloride, for which purpose sea water may be used, in order to dissolve out the calcium sulphate.—E. S.

Alloy adapted for Ornamentation. M. Wagner. Fr. Pat. 353,081, April 6, 1905.

FROM 65 to 76 parts of tin and from 20 to 25 parts of antimony, by weight, are fused together, and to the molten mass from 4 to 10 parts of arsenic are added. The mass is allowed to cool very slowly, or it is cast in previously heated moulds of iron or of sand. The alloy is rendered less friable by the addition to it of a small percentage of lead. The alloy shows crystalline ornamental figures on its polished sections, which figures may be made more conspicuous by treatment with acids, or by partial fusion. For some purposes, the alloy may be cast upon an iron or other resisting core. The alloy may also be cast into vases or the like as objects of ornament.—E. S.

Furnaces; Roasting — [for Ores, &c.]. F. J. Falding. Fr. Pat. 353,123, April 7, 1905.

SEE U.S. Pat. 788,098 of 1905; this J., 1905, 549.—T. F. B.

Air for Blast Furnaces; Process for Drying — Soc. E. Grimault, Le Soufaché, et Felix. First Addition, dated Jan. 18, 1905, to Fr. Pat. 349,219, Dec. 20, 1904. (This J., 1905, 677.)

INSTEAD of bubbling the air to be dried, through a solution of calcium chloride, as in the main patent, the air is passed through a perforated screen within a closed chamber so as to encounter a rain or spray of calcium chloride solution

falling from a cistern in the upper part of the chamber, the solution and chamber being cooled down to about -12°C . by means of a system of coiled pipes through which cold ammonia gas circulates as a cooling medium.

Bliss-Furnace Slag [for Decorative and Building Purposes : Manufacture of objects from —. Addition to Fr. Pat. 350,659, 1905. VIII., page 970.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(A.)—ELECTRO-CHEMISTRY.

ENGLISH PATENTS.

Cells; Improved Means and Appliances for Operating Electrolytic —. J. Burgeses, Farnworth-within-Widnes. Eng. Pat. 18,937, Sept. 2, 1904.

THIS invention relates to electrolytic cells designed for the decomposition of sodium chloride, the substance being charged into the cell in solid form in such a manner as to prevent it coming into contact with the electrodes or diaphragms until dissolved. The solid is charged into funnels which lead into tubular columns, the latter being built up of blocks, and the upper or lower corners, or both, of the blocks are cut away so as to form perforations or openings at the joints, these perforations being inclined upwards from the interior.—B. N.

Batteries; Impts. relating to Electric —. H. H. Lake, London. From La Soc. Anon. Le Carbone. Eng. Pat. 21,672, Oct. 8, 1904.

THE carbon electrode is surrounded by a suitable envelope containing the depolarising substance, such as a mixture of coke and peroxide of manganese. Around this is wound a sheet of blotting paper, or other porous material, thoroughly impregnated with a solution of a suitable electrolyte and then dried, so that the paper retains in its pores the active salts of the electrolyte in a solid state. The whole is then slipped into a zinc vessel acting as the other electrode, a washer of insulating material on the bottom of the vessel separating the two electrodes. An aperture in the cover of the vessel serves for the introduction of water.—B. N.

UNITED STATES PATENTS.

Furnace; Electric —. H. N. Potter, New Rochelle, N.Y., Assignor to G. Westinghouse, Pittsburg, Pa. U.S. Pat. 797,747, Aug. 22, 1905.

THIS invention relates to a method of supplying heat to the body of the furnace by utilising the latter as an electrical resistance, and adding to the heat thus produced the heat energy and electrolysis effects derived from a conducting gap, the heat of the furnace rendering the surrounding gas or vapour conductive. The terminal voltage is thus reduced so that the gap carries a current of lower voltage than that of the normal electric arc, and may also be regulated by varying the resistance of the circuit which includes the gap.—B. N.

Electrode of Electrolytic Apparatus. G. J. Atkins, Tottenham. U.S. Pat. 798,314, Aug. 29, 1905.

Aluminium, Silicon, Ferro-aluminium, Ferro-silicon, Aluminium Carbide, Aluminium Silicide, and Carbon Silicide; [Electricity] *Production of* — and *Application of the Products in the Reduction of Metallic Oxides*.—A. O. Viel and M. Jeantet. Fr. Pat. 353,070, April 1905.

MIXTURE of clay, kaolin, or aluminium sulphate with lime, or carbon, according to the product to be made, is fused in an electric furnace. One or more bodies thus produced, may be applied in reducing oxides, by inflaming a mixture of the oxides with such bodies.—E. S.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

Macassar Oil; *Schleichera Trijuga*; *The Seeds and Leaf* — D. Hooper. Agricult. Ledger, 1905, No. 1, 1905.

1903 extensive demands were made in Europe for the seeds of the *Kusum* tree, *Schleichera trijuga*, and this led to an inquiry by the Forest Department of India into the local uses and value of the tree. The fruit and seeds are used for food by local tribes in various parts of India and Burma, whilst the oil is employed for cooking and illuminating purposes, and medicinally as a purgative (in the Central Provinces), a prophylactic against cholera (in Bombay), for rheumatism (Bombay), and for skin diseases (in Malabar). The powdered seeds are used for roasting maggots. No oil is exported from any of the districts. 100 parts of seeds yield 66 parts of kernels, and after, on extraction with ether, were found to contain 10 per cent. of oil, corresponding to 40.5 per cent. in the seed. Another determination by Walker gave 10 per cent. of oil from the kernels. The tree is infested by the lac insect in the Central Provinces, and lac cultivation could not be successfully carried on at the same time as the cultivation of the fruit.

The oil (the original macassar oil) has been found to consist of glycerides of oleic acid (70 per cent.), palmitic acid (5 per cent.), and arachidic acid

(25 per cent.), and its characteristic is described by Glenk, and more recently by Walker (Chem. Centr., 1900, 253). Old specimens examined by the author had acid values of 26, and 26, and saponification values of 122 and 90.6, whilst the fatty acids melted at 35 and 36°C. respectively. Hydrocyanic acid was detected in each case. The wood is hard and durable, the heart wood being reddish brown and the sap-wood white.—C. A. M.

Fats; *Impts. in the Enzymic Decomposition of* — F. Hoyer. Seifensiederzeit., 1905, 32, 509, 510, 530, 531, and 546–548. Chem. Centr., 1905, 2, 582–583. (See this J., 1902, 1511; 1903, 639, 805, 873, 1094, 1137; 1904, 259, 550, 614, 1152.)

THE chief improvement which has been made in the process of decomposing fats by means of enzymes, consists in the use of the so-called "castor-seed extract" (this J., 1904, 619), in which the ferment is in a more concentrated condition than in the castor seeds themselves. By using the castor-seed extract only about 10 per cent. of the albuminoids contained in the seeds are brought into contact with the fat to be decomposed; the middle layer between the glycerin solution and the fatty acids is reduced in quantity, and the glycerin solution is purer. The middle layer is of a quite different character from those obtained by the earlier methods of working, and can be saponified directly for the production of emulsi and soap. The best working temperature is about 23°C. for oils, and 1–25°C. above the m. pt., for fats. The ferment loses its activity above 42°C. In the case of high-melting fats, the m. pt. must be lowered by addition of an oil or a low-melting fat. The author states that the quantity of the ferment required, appears to be directly proportional to the saponification value of the fat: for example, coco-nut oil requires at least 8 per cent., tallow 8–10 per cent., and linseed oil 5–6 per cent. The amount of water added should be about 35 per cent. of the weight of the fat; whilst to increase the activity of the ferment, an addition of 0.15 to 0.2 per cent. (on the weight of fat) of manganese sulphate dissolved in a small quantity of hot water is advantageous. The necessary quantity of water for the production of a satisfactory emulsion is added to the oil in the vessel in which the hydrolysis is to be effected, the mixture is at once heated to the working temperature, and then the ferment and manganese sulphate are introduced, the whole being agitated by a current of air. The vessel is then covered and allowed to stand. After 24 hours, about 80 per cent., and after 48 hours, 90 per cent. of the fat is hydrolysed. When castor seeds are employed, these are ground with the necessary quantity of water immediately before use, and the mixture allowed to settle, the supernatant milky liquid being used with the addition of 0.06 per cent. of acetic acid (on the weight of the fat), to effect the hydrolysis of the fat. After the hydrolysis is complete, the mixture, whilst being agitated by a current of air, is heated for 1–2 hours at 80°–85°C., a suitable quantity of dilute sulphuric acid being added shortly before this temperature is attained, in order to expedite the breaking up of the emulsion. The supplies of air and steam are then cut off, and the vessel is covered and allowed to stand. After 2–3 hours the main quantity of the clear glycerin solution can be run off: on standing overnight, complete clarification takes place, and 95 per cent. or more of the theoretical yield of glycerin solution can be separated, so the author states, whilst the fatty acids are obtained in an anhydrous condition. The middle layer when allowed to stand for several days yields a further quantity of glycerin solution, and is then washed and saponified. As the quantity of it is small compared with that of the fatty acids (3:100) it may, with advantage, be saponified with the latter. The clear glycerin solution is freed from sulphuric acid and then directly evaporated under reduced pressure, yielding a crude glycerin stated to be equal in value to saponification glycerin.—A. S.

ENGLISH PATENT.

Soap; *Manufacture [Moulding] of* — and *Apparatus therefor*.—F. Holoubek, Nüsch, Austria. Eng. Pat. 24,440, Nov. 11, 1904.

See Fr. Pat. 347,585 of 1904; this J., 1905, 338.—T. F. B.

UNITED STATES PATENT.

Oleic Acid; [Electrical] Process of Converting — into Stearic Acid. A. de Hemptinne, Ghent, Belgium. U.S. Pat. 797,112, Aug. 15, 1905.

SEE Eng. Pat. 1572 of 1905; this J., 1905, 448.—T. F. B.

FRENCH PATENT.

[Wax] Composition for use in Moulding Phonograph Records, and its Method of Manufacture. New Jersey Patent Co. Fr. Pat. 352,253, Feb. 14, 1905.

SEE Eng. Pat. 3070 of 1905; this J., 1905, 806.—T. F. B.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

(A).—PIGMENTS, PAINTS.

ENGLISH PATENTS.

Pigments; Manufacture of —. J. F. Bennett, Dronfield, and J. Mastin, Sheffield. Eng. Pat. 21,062, Oct. 1, 1904.

THE patentees claim the use of powdered glass, porcelain, or other materials of a vitreous nature for pigments of absolute permanence. The ordinary coloured glasses are not of sufficient richness of colour for the purpose. They therefore manufacture special glasses, intensely rich in colour, and either transparent or opaque. These are ground to impalpable powders, then mixed with the vehicles and the grinding continued, by which means the desired colour and tint are developed.—M. J. S.

Pigments; Manufacture of —. J. F. Bennett, Dronfield, Derby, and J. Mastin, Sheffield. Eng. Pat. 24,733, Nov. 15, 1904.

PORCELAIN or earthenware clay is mixed with suitable mineral substances, e.g., cobalt oxide, barium sulphate, and Paris white, and fired as usual. The coloured substance obtained is powdered and mixed as usual for crayons, distempers, printing inks, and the like.—A. G. L.

Lithopones; Process for the Preparation of —. R. Alberti, Goslar, Germany. Eng. Pat. 13,455, June 29, 1905.

To keep lithopones white, and prevent them from turning black or yellow in sunlight, an alkaline-earth or alkali peroxide, or hydrogen peroxide is added to the lithopone after it has passed through the incandescent process and has been washed. This may be done at the ordinary or at slightly elevated temperatures. If barium peroxide is used, about 2 per cent. is necessary. The peroxide may be also added to the dried lithopone before reduction.—A. G. L.

UNITED STATES PATENT.

Paint Composition. W. A. Hall, Bellows Falls, Vt. U.S. Pat. 797,683, Aug. 22, 1905.

SEE Eng. Pat. 26,903 of 1903; this J., 1904, 328.—T. F. B.

FRENCH PATENTS.

Paint; Process for the Manufacture of —. E. A. Rueh. Fr. Pat. 350,018, June 24, 1904.

CLAIM is made for the use of a compound of a drying oil with a metallic oxide, preferably alumina, as a base for the preparation of paints. The compound is prepared either by saponifying the drying oil directly with alumina, or by decomposing the alkali soap prepared from the oil with a soluble salt of aluminium. The insoluble aluminium soap is washed with water to remove soluble salts and glycerin, then carefully dried, ground with the colouring matter, and mixed with oil of turpentine to a suitable consistence.—A. S.

Minerals; Process and Apparatus for the Treatment of Sulphide and other — — [Manufacture of Pigments]. G. E. Kingsley. Fr. Pat. 252,608, March 22, 1905.

SEE Eng. Pat. 23,909 of 1904; this J., 1905, 681.—T. F. B.

Dyestuff specially suitable for the Manufacture of Lac Production of a Red Monoazo —. Badische Anilin und Soda Fabrik. Second Addition, dated March 1905, to Fr. Pat. 346,008, Sept. 2, 1904. IV., page 1.

(B).—RESINS; VARNISHES.

Resin; Garcinia — from Perak, Federated Malay States. Bull. Imp. Inst., 1905, 3, 149—150.

THE resin examined was obtained from the sap of a species of *Garcinia* which has not been identified: it appears to be quite different in constitution from gamboge, which is obtained from *Garcinia Hanburii* and *G. morella*. The resin is prepared by boiling the sap until it is as thick as cream, and then adding a little oil of turpentine to form a pale yellow emulsion. It is then boiled until all the water is evaporated, it solidifies, and is then insoluble in oil of turpentine, but it may be made into an emulsion by the immediate addition of water. The emulsion is stable and gives a nearly white, very hard and brilliant coating, equal to that obtained with Japanese lacquer. A specimen of the resin examined was soft and opaque, and had an odour resembling that of tung oil. It was covered by a very thin layer of brittle material, insoluble in turpentine oil and the usual solvents, and perfectly identical with the insoluble resin mentioned above. The soft resin was soluble in oil of turpentine, chloroform, benzene and ether, and almost completely so in alcohol. It melted at 65° C., and yielded 0.21 per cent. of ash. It contained a large proportion of free resin acids, a comparatively small amount of resin esters, 1 "gram" requiring 89.2 mgrms. of potassium hydroxide for neutralisation and 93.5 mgrms. for complete saponification. The solution of the resin in oil of turpentine yielded a hard, nearly white coating, similar to that produced by dammar varnishes.—A. S.

ENGLISH PATENTS.

Varnishes and Oil Colours; Process for Separating and Recovering the Residues of —. A. Gottschalk. Fr. Pat. 352,880, March 31, 1905.

SEE Ger. Pat. 158,310 of 1904; this J., 1905, 681.—T. F. B.

Lacquers or Varnish; Process for the Manufacture of —. L. Lederer. Fr. Pat. 352,897, April 1, 1905.

CLAIM is made for the use of acetylene tetrachloride alone or mixed with other solvents in the manufacture of varnishes and lacquers. Special reference is made to the use of acetylene tetrachloride as a solvent for esters of cellulose for the purpose of preparing lacquers or varnishes, but the solvent named may also be employed in the preparation of resin varnishes.—A. S.

(C).—INDIA-RUBBER, &c.

Rubber from the Sotik Forest, East Africa Protectorate. Bull. Imp. Inst., 1905, 3, 146—147.

THE rubber was obtained from a species of *Landolphia*, probably *L. ugandensis*. The specimen examined was somewhat soft, but exhibited good elasticity and tenacity, and was free from stickiness. It was soluble in ether, benzene and carbon bisulphide, and partially soluble in chloroform. It contained: Caoutchouc, 78.3; resin, 1.1; moisture, 6.2; dirt and insoluble matter, 6.4; ash (included in "dirt"), 2.4 per cent. The rubber was valued at from 3s. to 3s. 6d. per lb.—A. S.

Rubber of Ficus Elastica from the Madras Presidency. Bull. Imp. Inst., 1905, 3, 147—148.

THE specimen of rubber examined was fairly tenacious and

ie, somewhat moist, but not sticky. It contained: catechou, 85.2; resin, 7.8; albuminoid matter, 1.1; ure, 3.7; dirt and insoluble matter, 1.9; and ash (deducted in "dirt"), 0.5 per cent. It was valued at from 1d. to 3s. 9d. per lb. — A. S.

ENGLISH PATENT.

Rubber; Method of Separating or Coagulating and Appliances therefor. R. C. Thomson, Glasgow. From D. K. Michie, Colombo, and G. H. Colledge, Ceylon. Eng. Pat. 330, Jan. 7, 1905.

The coagulation of the rubber is effected by subjecting latex, mixed, if necessary, with a small quantity of acetic acid, to centripetal combined with centrifugal motion. The apparatus for carrying out the process consists of a cylindrical vessel mounted on a rotating vertical spindle supported by a frame. On the inner surface of the rotating vessel are a number of vertical projections or ribs which serve to guide the latex towards the centre. To the top of the outer frame is bolted a ring, from which curved vanes project downwards into the cylindrical vessel. These vanes do not extend to the rim of the vessel, a free space being left in which the coagulated rubber forms a sponge-like ball which is removed when of the proper consistence. It is stated that the time occupied in the separation of the rubber is 15 to 15 minutes. — A. S.

FRENCH PATENTS.

Rubber; New Process for Joining or Cementing — G. A. Le Roy. Fr. Pat. 349,981, June 13, 1904.

Two surfaces of the rubber to be cemented together are superficially melted by the application of a hot sheet of metal; the excess of melted rubber is removed by scraping or by employing a solvent, and the surfaces are coated with a vulcanising compound such as, for example, a chloride, iodide or fluoride of sulphur (a mixture of these), applied as a solution in benzene, carbon bisulphide or tetrachloride. The coated surfaces are then applied to each other. The preliminary fusion of the rubber is intended to retard the vulcanising action of the sulphur compound or compounds, which would otherwise be too rapid. — M. C. L.

Rubber Solutions; Process for the Preparation of — and Utilisation of such Process for the Regeneration of Rubber. Robinson Bros., Ltd., and G. A. L. Clift. Fr. Pat. 352,371, March 14, 1905. Under Int. Conv., March 17, 1904. Eng. Pat. 6471 of 1904; this J., 1905, 449. — T. F. B.

IV.—TANNING, LEATHER, GLUE, SIZE.

UNITED STATES PATENT.

Leather; Treating Raw or Partially Dressed — H. W. Southworth, London. U.S. Pat. 797,982, Aug. 22, 1905.

Fr. Pat. 344,441 of 1904; this J., 1904, 1104. — T. F. B.

FRENCH PATENTS.

Tanning; Rapid — R. Berthon. Fr. Pat. 352,700, March 27, 1905. (See also this J., 1905, 339 and 449.)

Leather skins after depilation are immersed in a solution of sodium chloride (6 to 8 per cent.) and hydrochloric or sulphuric acid (three to four per thousand) for 24 to 48 hours. They are half dried and are then ready to be tanned. Instead of this pickling process the pelts may be subjected to the action of an alternating electric current, the goods being suspended between plates of lead which act as electrodes, in a solution of salt and acid as stated above. The goods are afterwards treated in the same way with a solution (4 to 5 per cent.) of free tannin, free from glucosides. The tanning solution is freed from glucosides by treating the solution with

sprouted barley or potatoes for 18 hours at 60° C. The glucosides combined with tannin retard the tanning process and render the leather brittle, though free from side effects of no detrimental effect. The tanning may be completed by the process of "laying away" in pumice. — M. C. L.

Bricks or Agglomerates of Cork and Tannin. Bickel. C. C. Girod. Fr. Pat. 353,071, April 6, 1905. IX., page 972.

XV.—MANURES, Etc.

ENGLISH PATENT.

Manure from Offal and the Like; Improved Process of and Apparatus for Manufacturing Artificial Manure. C. Bollé, Manchester. From C. Schmidt and Co., Leipzig. Eng. Pat. 23,015, Oct. 26, 1904.

In order to effect economy in the quantity of acid required for the decomposition of waste animal substances and to obtain a product requiring a minimum amount of drying to convert it into a solid powder, the steaming of the offal and the treatment with acid are carried on in separate vessels, the excess of condensed water and the fat being removed before the acid is added. The steamer or digester is a vertically-placed cylindrical vessel, divided into two compartments, an upper and a lower, by a horizontal flap which can be lowered from the outside. The materials are charged into the upper compartment, where they become warmed by the waste steam from the lower compartment. By opening the flap they are allowed to fall into the lower compartment, where they are submitted to an adequate steaming. The excess of water and the oil are then drawn off below by a cock, after which a slide at the bottom is drawn out and the steamed material falls gradually into the disintegrator, being sprayed during its descent with acid blown in by an injector. In consequence of the previous removal of the excess of water, the material soon absorbs the acid, and much less is thus required for the necessary degree of concentration, than is the case where steaming and treatment with acid are simultaneous. — M. J. S.

UNITED STATES PATENT.

Manures; Manufacture of Humous — J. J. Boutan. First Addition, dated April 22, 1904, to Fr. Pat. 338,981, Aug. 13, 1903. (This J., 1904, 1037.)

In the preparation of the "humo-phosphatic" manures described in the main patent, it is now preferred to treat the peaty matter with the pasty product obtained by acting on insoluble phosphates with such a proportion of sulphuric acid as may set free the phosphoric acid.

— E. S.

XVI.—SUGAR, STARCH, GUM, Etc.

Starch; Products of Hydrolysis of — by Hydrochloric Acid [New Modification of Dextrose], and their Influence in the Saccharal Industry. A. Roessing. Chem.-Zeit., 1905, 29, 867—873.

In previous communications (see this J., 1903, 886; and 1904, 386, 953) the author described a method for the determination of dextrose in starch syrups by the action of baryta water, and showed that certain syrups prepared by hydrochloric acid yielded abnormally high results. When, as in the manufacture of sweetmeats, these abnormal syrups are melted with cane sugar, they yield deliquescent products, the practical consequence being that starch syrups converted by hydrochloric acid are considered to be unsuitable in that industry. The peculiarity of these syrups is now shown to be due to the presence of a new modification of dextrose, termed provisionally "ε-dextrose." It is formed when excessive conversion temperatures of 130° C. and upwards in conjunction with hydrochloric acid are adopted; when sulphuric acid is employed the products are entirely normal at tempera-

tures up to 100 °C., so that abnormal syrups prepared with sulphuric acid are comparatively rare. Abnormal dextrose hydrate, as prepared by the author by heating starch or pure dextrose with hydrochloric acid under pressure, remains fluid, when heated at 100–105 °C. after all the water has been driven off; the anhydride thus obtained is extremely hygroscopic. This form of dextrose readily yields the alternative (Skrapp's) form of the phenylhydrazone, which is only rarely obtained from normal dextrose. By the action of baryta water under standard conditions, abnormal dextrose suffers a decrease in cupric-reducing power about three times as great as normal dextrose. The action of baryta water on the two forms of dextrose results in the production of organic acids, chiefly lactic acid, which takes place without absorption of oxygen. The dextrins of abnormal starch syrups are also abnormal, the unfermentable residue being distinguished by its great hygroscopicity and abnormally high cupric-reducing power. The hygroscopic nature of abnormal dextrose anhydride and the abnormal dextrins causes the deliquescence or softening of the cane sugar melts to which they are added; this action is still further aggravated by the inversion of the cane sugar produced by the ash constituents of starch syrups converted by hydrochloric acid. All these syrups contain acid phosphates and chlorides, including calcium chloride. At the temperature of the sugar melt these constituents react with the production of free hydrochloric acid, which inverts the cane sugar. Syrups converted with sulphuric acid are generally free from soluble phosphates and contain very little ash. The proportion of dextrose to dextrin in a starch syrup has no influence on the hygroscopicity of the sweetmeat products, the only question being the normal or abnormal nature of the components of the syrup. J. F. B.

UNITED STATES PATENTS.

Cane Juices; Preparation for Clarifying — G. B. Williamson, U.S. Pat. 797,391, Aug. 15, 1905.

The preparation used for clarifying cane juices and syrups consists of bone-black dust (1 lb.), sulphuric acid (0.75 lb.), and water (1 lb.).—T. F. B.

Sugar; Process of Making — J. V. P. Lagrange, Paris, U.S. Pat. 797,965, Aug. 22, 1905.

SEE Eng. Pat. 21,151 of 1902; this J., 1903, 504. —T. F. B.

Bone Black (Revivifying) Kilm. B. Eba, Warren, Pa., U.S. Pat. 796,304, Aug. 1, 1905.

A RETORT for revivifying bone-black and similar materials is composed of upper and lower sections, the upper section having openings in its walls shielded by guards placed over them inside the section; the lower section has an enlarged upper end, into which the upper section fits; this enlarged end is provided with passages for the exit of vapour; inside the lower section, terminating at a short distance from the walls, are a number of deflectors to conduct the vapours towards the spaces mentioned above. The retort is set in a kiln, in a chamber communicating with the fire-grate. —T. F. B.

FRENCH PATENTS.

Masseculites [Sugar]; Process and Apparatus for Boiling — with Circulation, H. Roy, First Addition, dated Feb. 6, 1905, to Fr. Pat. 337,227, Dec. 1, 1903. (See this J., 1904, 616.)

MEANS are described whereby the exact position of the sliding tube, through which the masseculite is withdrawn for circulation, can be ascertained. The internal sliding tube is attached at its upper end to a carrier-bar parallel with the tube. This bar passes through a separate orifice in the bottom of the pan, and terminates in a screw thread by which the movement of the sliding tube is effected, and its position is indicated by a pointer. A special form of re-heater is described, also an arrangement by which the principle of circulation can be applied to existing pans; this consists of a vertical slit cut in the side of the pan and a sliding gate which moves in a casing fixed externally over the slit. —J. F. B.

Crystals [Sugar]; Process for Obtaining Good, Chemically Pure — V. Schütze, First Addition, dated Feb. 14, 1905, to Fr. Pat. 339,896, Jan. 26, 1904. (This J., 1904, 708.)

THE apparatus which is specially adapted for the crystallisation of sugar from syrups, consists essentially of an internal and external horizontal cylinder, so mounted to be capable of very slow rotation or of to-and-fro movement, the space between the two cylinders being adapted for the circulation of a fluid which may serve to heat or cool the interior, the course of such fluid being helical. A vacuum is formed and maintained within the internal cylinder, into which the hot syrup (at a stated temperature and density) is admitted, as it becomes concentrated and cooled at the farthest end of the cylinder, crystals are formed, which are discharged into a receptacle, also vacuum. The heating fluid circulates in the jacket on the counter-current system. —S.

Best Sugar; Process of Making — M. Roeck, A. Schaer and H. W. Hünz, Addition, dated Jan. 15, 1905, to Fr. Pat. 315,290, Aug. 1, 1904.

SEE U.S. Pat. 770,700 of 1904; this J., 1904, 994. —T. B.

Gas from very Light Combustibles, such as Straw, Bagasse, &c.; Generator for the Production of Mixed Gas, du Gaz, H. Riché and C. P. Bratasiano, Fr. Pat. 352,908, April 1, 1905. H., page 961.

XVII.—BREWING, WINES, SPIRITS, &c.

Malt Grist from Different Mills. O. Reinke, A. Brau., 1905, 22, 452–453.

IN grinding malt to determine the proportion of grist to flour, the percentage of moisture is a very important factor which has to be taken into account; the influence of high kilning is of less importance. In grinding malt on the practical scale, it is desirable that the proportion of hulls and flour should be as small as possible; in the case of flour for filter-press work, the hulls should be sifted off and mashed separately.

In the principal malt-mills of German make, the following adjustments all give equivalent results as regards yield of extract:—

	Amme, Giesecke and Konegen	Luther.	
	4 rollers.	2 rollers.	2; 5
For fine grist—			
Top pair	0.2 mm.	1.5	
Bottom pair	0.05 mm.		
For coarse grist—			
Top pair	0.6 mm.	6.0	
Bottom pair	0.6 mm.		

The finer the grist the longer is the time required for saccharification. The results of grinding should therefore be controlled by sifting and weighing the hulls, grist and flour. In grinding to flour, the malt should first be broken up in the cone-mill before the grinding, otherwise too many fine shreds of hulls will be present. —J. F. B.

Malt and Beer; Influence of the Duration of Germination on the Nitrogenous Constituents of — A. I. da Z. ges. Brauw., 1905, 28, 576–578 and 590–592.

IN the valuation of brewing barleys, the nature of the nitrogenous substances is a factor of far greater importance than their absolute total quantity. A good brewing barley should not contain much more than 1 per cent. of soluble albuminoids; this low proportion of soluble albuminoids is frequently, but not always, accompanied by a maximum of 10 per cent. of total albuminoids. It is a particularly good characteristic if a large proportion of the soluble albumin is coagulable, and treatment on the malting floor should be regulated according to the quantities of soluble and coagulable albuminoids in the barley. The higher the quantity of

the albuminoids, the more protracted should be the treatment, especially when the coagulable albuminoids are present. Too short a growth is shown by low proportions of extract, soluble albuminoids and coagulable albuminoids; forced growth is shown by a high proportion of extract and a low proportion of coagulable albuminoids. Unfavourable proportions of soluble and coagulable albuminoids in the barley can generally be corrected by suitable treatment. In the malting of barleys rich in soluble albuminoids, the time on the floor should be sufficiently long to ensure a rapid saccharification (to avoid starchiness); the quantity of soluble albuminoids in the malt should be about 3.5 per cent., i.e., about 35 or at the most 38 per cent. of the total albuminoids (to avoid gluten diseases). With a proportion of soluble albuminoids of 2 per cent., there is a tendency to excessive attenuations and hazes. In such a case, the proportion of nitrogenous extract can be regulated by extending the time of treatment, but the improvement is often obtained at a cost of an appreciable loss of extract. In the case of malt, if the albuminoids are properly modified, the proportion of coagulable albumin should be low. If, however, the proportion falls below 0.1 per cent. without the saccharifying power and quantity of soluble albuminoids being satisfactory, an improvement in these relations can be obtained by extended floor treatment, but only at the expense of the extract. Bohemian and Moravian barleys are most suitable for giving malts with good saccharifying power and normal proportions of soluble albuminoids. Prolonged floor treatment without excessive losses of extract.—J. F. B.

Cause of the Presence of Abnormal Quantities of Tannin in Bruised —. G. Wareollier. *Comptes Rendus*, 1905, 141, 403—408.

Apples are frequently gathered in the unripe state and allowed to ripen on a dry floor. A considerable portion of the fruit is bruised by careless handling during harvesting and transport, and the bruises so produced not only afford entrance to micro-organisms, but turn into a zone in which the apple starch remains completely unsaccharified even when the rest of the fruit is opened or decayed. The browning of the bruised zone is due to the action of an oxydase upon the tannin which exudes from the ruptured cells. The author now shows that it is the paralysing action of this tannin upon the diastase, which prevents the saccharification of the starch, upon which normal ripening depends. Experiments showed that the presence of 0.2 per cent. of gall-nut extract or 0.075 per cent. of apple tannin completely prevented the saccharification of a 1 per cent. starch solution by one-tenth of its volume of a 10 per cent. malt extract at 62° C.

Consequently, it is concluded that the rupture of the apple cells causes the tannin to escape and to coagulate the diastase in the fruit, and that the consequent paralysis entails a serious loss of sugar to the cider manufacturer. —J. F. B.

Rapid Vinegar Generators; Processes occurring in the "Rapid" —. F. Rothenbach. *Deutsche Essigind.*, 1905, 9, 220. *Chem. Centr.*, 1905, 2, 581—582.

In the "rapid" vinegar generators, only a very small quantity of aldehyde is produced under normal conditions, the fragrant ester with an odour different from that of acetic acid being formed in somewhat larger amounts. Acetic fermentation must be caused by an enzyme (zymes) secreted by the acetic bacteria, since it can be produced by dead bacteria; the presence of these enzymes can, however, be detected by the gnaiaenm reaction. Acetic processes also appear to play a part in the rapid generators. A generator which had been previously filled with the ordinary mash employed in the rapid process, was charged with a wine mash, when it was found that the amount of "extract" contained in the vinegar was the same after 24 hours as at first, viz., 0.720 gm. per 100 gm. mash; after 4 days, the quantity had increased to 0.8058 gm.; after 8 days to 0.8875 gm.; after 10 days to 1.0472 gm.; after 12 days to 1.1531 grms.; after 14 days to 1.2100 gm., and after 18 days to the maximum of 1.2873 grms.

per 100 c.c. According to the author, the ratio of the proportion of "extract" in the vinegar to the proportion of the wine mash is absorbed by the composition of wood used as filling material for the generator, and is then slowly given up again according to the laws governing osmotic processes.—A. S.

Acetic Bacteria; Enzymic Fermentation of —. F. Rothenbach and L. Eberlein. *Deutsche Essigind.*, 1905, 9, 233—234. *Chem. Centr.*, 1905, 2, 642—643.

The authors determined the amount of acetic acid produced by the action on alcohol of dead acetic bacteria obtained from a pure culture of *Bact. pasteurianum* by destroying the cells mechanically and then treating them with acetone and ether. In a parallel experiment without addition of alcohol, the amount of acid formed was 0.7 gm. less than with alcohol, and the difference must be attributed to enzymic action. Rothenbach had observed previously that when the preparation known as permanent acetic bacteria ("Daueressigbakterien") from *Bact. acetigenum* and *B. ascendens* is triturated with kieselsol and sea-sand, an acid odour is produced. Three grms. of the permanent bacteria from *Bact. pasteurianum* were triturated with water and 1.5 grms. each of sea-sand and kieselsol for 12 minutes, when it was found that 0.4 gm. of acetic acid had been produced. (See also Buchner and Meisenheimer; this J., 1903, 374.)—A. S.

ENGLISH PATENT.

Brewer's Wash, Sewage or Spent Dyes and the like; Evaporator for Evaporating the Liquid in —, the Evaporator being also applicable as a Smoke Washer. A. B. Lennox. Eng. Pat. 18,488, Aug. 26, 1904. XVIII.B., page 982.

FRENCH PATENT.

Wine Must; Process of Fermenting Red —. A. Fuchs. Fr. Pat. 352,480, March 17, 1905.

The must is fermented in a closed tun provided with a suitable fermentation floor of laths covered with muslin; the tun is only partially filled with must, and is rotated from time to time during the fermentation, the carbon dioxide being allowed to escape by vents provided for the purpose.—J. F. B.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS.

(A.)—FOODS.

ENGLISH PATENTS.

Milk-food for Infants and others, and Method of Manufacture. J. R. Hatmaker. Paris. Eng. Pat. 20,339. Sept. 21, 1904.

CLAIMS are made for a soluble, powdery milk-food containing approximately: casein, 24; butter-fat, 12; milk sugar, 54; milk salts, 5; and moisture, 5 per cent., and for the process of preparing it, which consists in exposing a liquid of suitable composition in a thin layer or film upon a surface heated to above 212° F., until only sufficient water for its good preservation remains. The liquid is obtained by adding milk sugar to cows' milk from which a portion of the cream has been removed.—T. H. P.

Milk-food for Infants and others, and Method of Manufacture. J. R. Hatmaker. Paris. Eng. Pat. 20,340. Sept. 21, 1904.

SIMILAR claims to those in the preceding specification are made, the approximate composition of the food being in this case: casein, 20; butter-fat, 20; milk sugar, 50; milk salts, 5; and moisture, 5 per cent.—T. H. P.

UNITED STATES PATENTS.

Wheat, Flour and other Cereals; Process of and Apparatus for Improving, Bleaching or Conditioning — W. T. Mercier, Belfast, Assignor to The Ozonised Oxygen Co., Ltd., Manchester. U.S. Pats. 796,339 and 796,340, Aug. 1, 1905.

SEE FR. Pat. 343,805 of 1901; this J., 1904, 1049. — T. F. B.

Milk; Process of Making Peptoms — J. H. Campbell, Brooklyn, N.Y., Assignor to National Nutrient Co., Jersey City, N.J. U.S. Pat. 796,496, Aug. 8, 1905.

MILK is partially peptonised and then dried to a powder at a temperature of about 136° F., so that the action of the added ferment is stopped but not destroyed. On the addition of water to the powder, the solids of the milk are further peptonised. — W. P. S.

Separator; Milk; Centrifugal Liquid — M. H. Matty, Clayton, N.Y., Assignor to M. Decker, Chicago, Ill. U.S. Pat. 797,969, Aug. 22, 1905.

THE bowl of the separator consists of a cylindrical vessel surmounted by a conical cap, in which is an opening for the cream. A tube for the whole milk, passes down through the cap, concentrically with the bowl and terminates in a cone resting on the bottom of the bowl. The interior of the bowl is divided by a number of cylindrical conical partitions, having notches into which fit ribs placed on the central tube. The partitions have vertical openings near the centre and horizontal openings in their peripheries. A number of tubes arranged round the bottom of the bowl, lead from the outer partition to the conical termination of the central tube. — W. H. C.

(Cream) Separator; Centrifugal — P. H. Watts, Dursley, U.S. Pat. 798,243, Aug. 29, 1905.

SEE ENG. Pat. 11,732 of 1904; this J., 1905, 509. — T. F. B.

Butter; Process of Reparing — S. S. White and J. H. Strong, Wadena, Minn. U.S. Pat. 797,481, Aug. 15, 1905.

THE butter is washed several times with water or brine at a temperature of 85° F. It is then worked with milk, cream or ripened milk; colouring matter and salt are added, and, finally, about 5 per cent. of water is incorporated with the mass. — W. F. S.

Meat Meal; Process of Preparing — E. Matagliano, Genoa, Italy. U.S. Pat. 798,438, Aug. 29, 1905.

SEE ENG. Pat. 15,440 of 1904; this J., 1905, 685. — T. F. B.

(B.)—SANITATION; WATER PURIFICATION.

ENGLISH PATENTS.

Water and Sewage, &c.; Regenerative Heating Apparatus for the Purification of — C. Tuckfield and W. G. de F. Garland, East Molesey. Eng. Pat. 16,689, July 29, 1904.

THE sewage is pumped into the lower part of a vertical cylinder in which is suspended a smaller cylinder provided with a tube plate at each end and a number of tubes connecting these plates. The liquid rises through the tubes and round the outside of the smaller cylinder until it reaches a steam coil placed in the larger cylinder, and immediately above the smaller one. The temperature of the sewage is thus sufficiently raised to sterilise it and to cause most of the impurities to fall to the bottom of the cylinder. The heated liquid then passes from the top of the cylinder through a pipe, which conducts it into the interior of the small cylinder, where it comes in contact with the outside of the tubes up which the impure sewage is flowing, and finally leaves the apparatus nearly cold. The sterilised sewage may be allowed to flow through a closed settling tank before it enters the smaller cylinder. As the treated liquid leaves the apparatus under pressure, it may be employed to actuate a hydraulic engine, water-wheel, or the like, and the power obtained utilised to aid in driving the feed-pump. — W. P. S.

Brewers' Wash, Sewage or Spent Dyes and the Evaporator for Evaporating the Liquid in — The Evaporator being also applicable as a Smoke W. A. B. Lennox, Newcastle-on-Tyne. Eng. Pat. 1 Aug. 26, 1904.

FIXED portions are attached to the lower ends of division plates placed in the apparatus described in Pat. 13,227, 1904 (this J., 1905, 811). When the portions hang vertically, the hot air takes a course through the compartments, but on raising each portion cuts off one of the compartments, or hot air, or smoke, passes straight to the chimney, or all of the compartments may be cut off at one time. — W. J.

Filter-Beds for Sewage or other Purposes; Impts. in — M. J. Adams, Stockfield on Tyne. Eng. Pat. 1 Sept. 9, 1904.

THE sewage is caused to flow in a shallow layer series of slightly inclined troughs. The troughs are formed of a material having a granular surface on which bacteria may grow, or they are covered with a thin layer of granular material. — W. H. C.

Sterilising and Purifying Water and other Liquids — Freyssinge and R. Roche, Paris. Eng. Pat. 2 Oct. 7, 1904.

SEE FR. Pat. 345,148 of 1901; this J., 1904, 1232. — T. F. B.

Filters; Impts. in — A. Howatson and W. Eng. Pat. 21,644, 1904. L., page 958.

Water; Decanting Apparatus for Purifying — G. Pulinx and C. A. G. Pulinx, Lille, France. Eng. Pat. 8366, April 19, 1905. Under Int. Conv., May 16,

THE apparatus consists of a vertical cylindrical vessel in which the water and the added reagent enter through a central pipe reaching nearly to the bottom of the vessel. The water then slowly rises in the interior of the vessel, which is provided with truncated conical diaphragms which the precipitate settles. The central tube is provided with plugs on its exterior which close the lower ends of the diaphragms. This tube may be raised to permit the simultaneous opening of all the plugs so that the sediment may fall round the outside of the tube to the bottom of the apparatus, where it is discharged through an opening provided for the purpose. The clear water passes through a filter at the top of the vessel and is then run off. — T. F. B.

UNITED STATES PATENTS.

Water; Process and Apparatus [Lime-water Softening] for Purifying — H. Reiser, Cologne, Assignor to H. Heiser Co., Germany. U.S. Pats. 796,088 and 796,088, Aug. 1, 1905.

SEE ENG. Pat. 967 of 1903; this J., 1904, 74. — W. S.

Water-Purifier — C. L. Kennicott, Chicago, Assignor to Kennicott Water Softener Co., Ill. U.S. Pat. 71290, Aug. 15, 1905.

THE apparatus consists of a rocking vessel divided into two compartments, and a spout for delivering the water into this vessel. The latter is connected by means of a sprocket wheel, ratchet and chain to a shaft provided with a number of arms and cups placed in a tank above the rocking vessel. As the shaft rotates, the cups intermittently discharge a chemical solution from the tank into the compartments of the rocking vessel. — W. P. S.

Water; Apparatus for Softening and Purifying — H. H. Sutro, New York, and L. M. Booth, Plainfield, N.J. U.S. Pat. 797,759, Aug. 22, 1905.

A VERTICAL cylindrical vessel is divided into several compartments, one of which serves as a reaction tank, and the other as a lime-water tank. A second compartment serves as a settling tank. The water is delivered into the apparatus in two regulated streams, one being led to the lower part of the lime-water tank and the other to a mixing pipe communicating with the reaction tank, where it is mixed with the water from the lime-water tank. — W. P. S.

of lime and other reagents are conducted from separate vats to the mixing pipe, the supplies being regulated by valves actuated by the flow of crude water. The treated water is led to the settling tank and withdrawn from the upper part of the latter. A sludge pipe, having numerous branches, is provided at the bottom of the settling tank.—W. P. S.

Fr.; Apparatus for Softening and Purifying — H. Sutro, New York, and L. M. Booth, Plainfield, U.S. Pat. 797,760, Aug. 22, 1905.

The apparatus consists of a lime-water tank, a reaction tank and a number of superposed settling tanks. The water to be treated is supplied to the lime-water and reaction tanks, and from thence by separate pipes to the settling tank. The upper settling tank is provided with a filter through which the purified water is drawn off.—W. P. S.

Fr.; Process for the Purification of — E. Declercq, 1st Addition, dated March 7, 1905, to Fr. Pat. 348,375, v. 30, 1904 (this J., 1905, 510).

A quantity of precipitate obtained in a previous treatment of the water is added to the latter before introducing chemical reagents, in order to increase the rapidity of precipitation. The water is conducted into a tank giving a conical bottom. A portion of precipitate is removed from the bottom of the tank to the channel conveying the water to the tank, the reagents being supplied by another pipe. The mixture enters through the stem of an inverted funnel suspended in the tank, from which the heavier part of the precipitate falls into a funnel placed above the bottom of the tank and is drawn off when necessary, whilst the finer part, settling on the conical bottom, is pumped into a further supply of water. The treated water is drawn off from the top of the tank.—W. P. S.

Eng. Pat. 6055 of 1905; this J., 1905, 937.—T. F. B.

Waters of Paper Mills; Recovery of Residual Alkalis from, and Clarification of — M. Erfurt, U.S. Pat. 352,524. XIX., page 984.

(C.)—DISINFECTANTS.

UNITED STATES PATENT.

Septic Compound [from Succinic Peroxide Acid]. M. Clover, Ann Arbor, Mich. U.S. Pat. 798,043, g. 22, 1905.

A disinfectant compound is prepared by adding a basic succinate to succinic peroxide acid (see Eng. Pat. 8415 of this J., 1904, 834). Its aqueous solution has a powerful germicidal action; when acidified with a mineral succinic peroxide acid is formed; on standing, it decomposes to the salts of succinic acid and succinic monoxide, and on prolonged standing, hydrogen peroxide is evolved.—T. F. B.

FRENCH PATENT.

Disinfectants; Fluorescent — E. Turpin. Addition, dated Jan. 31, 1905, to Fr. Pat. 346,363, Sept. 20, 1904 (this J., 1905, 148, 854).

Disinfectants, either alone or mixed with fluorescein, phthalaldehydes, other phthalaldehydes may be employed as disinfectants, either alone or mixed with fluorescein. Phthalaldehydes of quinine, quinone, hydroquinone, phenol, thol, pyrogallol, &c., and their derivatives in general can be used.—W. P. S.

XIX.—PAPER, PASTEBOARD, Etc.

Papers; Durability of — and *Testing same*. J. P. Nischilgen. Papier-Zeit., 1905, 20, 2570—2572 and 22—2723.

Papers for permanent records and hard wear should only be made from strong, sound rags; old and tender rags

give a paper which deteriorates rapidly by use. The nature of the sizing is probably of little importance, provided it has been properly incorporated. The tensile strength is of importance from the point of view of durability, owing to the fact that the strongest papers are generally those made from long and stout fibres, and include those papers of which the fibres are beaten wholly or partly to fine fibrille which interlace well and the presence of which is the best guarantee of long working qualities. The tensile strength is greater in the machine way than in the cross way, whereas the breaking stretch is greater in the cross way owing mainly to the longitudinal tension under which the paper is dried. Consequently a book of which the paper is folded in the cross way will be less durable than one in which the binding folds are parallel to the machine way. The author argues strongly against the custom of judging a paper by the mean tensile properties of the two directions; for durability, it is only the weakest direction which counts, and the specifications should state minimum values for breaking length and stretch. Rag papers are easily made with a ratio of 66 per cent. between the weakest and the strongest directions; the best rag papers properly beaten will even show ratios of 85—90 per cent. Short-fibred papers from straw, esparto and deciduous wood cellulose are easily made with a ratio of 60—65 per cent., but papers composed of coniferous wood cellulose generally show a ratio of only 40—50 per cent. between the two directions. In such cases the mean strength gives a very false idea of the real strength. The most important mechanical test for durability is the loss of tensile strength and elasticity produced by folding the paper backwards and forwards a given number of times (say, five double creases) under standard conditions in the Schopper creasing machine. A paper containing a high proportion of gelatinised cellulose [wet beaten] generally possesses extremely high tensile qualities, but it may be very brittle and of low durability, in which case it will be immediately condemned under the folding test. By means of the folding test also the presence of weak or old rag fibres, deficient beating, bad felting, over-drying and hydrocellulose are detected. Wood celluloses and other rag substitutes show up badly under this test. The author suggests that, if lignified fibres be excluded, the specifications of the German "normal" papers can be made efficient measures of durability without making any reference to the fibrous composition. A kind of natural selection in these respects will be made by specifying a minimum breaking length and stretch together with a maximum loss of these values after the folding test. For instance, "normal" papers of the first class should have a minimum breaking length of 5000 m., minimum breaking stretch of 3.5 per cent., and a maximum decrease in these values after five double creases of 20 per cent.—J. F. B.

ENGLISH PATENTS.

Papers; Manufacture of Blotting and other Water Loaf — C. Beadle and H. P. Stevens, London. Eng. Pat. 19,478, Sept. 6, 1904.

A sufficient quantity of dilute hydrochloric acid is added to the washed rags or other fibrous material used in the manufacture of paper, to neutralise the basic mineral matters contained in the rags, &c., and also in any water with which these materials are mixed. The quantity of acid employed is ascertained by experiment. Paper thus prepared can be used repeatedly for blotting ink without becoming non-absorbent.—W. P. S.

Paper Yarns; Process for Improving — M. Höllen. Eng. Pat. 7140, 1905. VI., page 965.

UNITED STATES PATENT.

Solvent for Nitro Derivatives of Carbohydrates. R. N. Riddle, Uwehland, Pa., Assignor to the Warner Chemical Co., Carteret, N.J. U.S. Pat. 797,373, Aug. 15, 1905.

PHENYL acetate is used for dissolving nitro derivatives of carbohydrates (e.g., nitrocellulose).—T. F. B.

FRENCH PATENTS.

[Paper] Composition; Incombustible, Non-Putrefying —, Unattacked by Acids. A. Andrieu. Fr. Pat. 349,982, June 13, 1904.

SIXTY kilos. of "crocidolite" fibres [wool-like fibre, of bluish tint, and mainly a terrous silicate] are mixed for a few minutes with 200 litres of water, and then for 15 minutes with 15 kilos. of powdered mica and 10 kilos. of kaolin. Five kilos. of waste of aloes, defibred and bleached, 5 kilos. of powdered starch, and 5 kilos. of pure gelatin are then added and the whole mixed for another 30 minutes, after which the homogeneous mass obtained is manufactured as usual into paper (for bank-notes, securities, &c.), insulating material, &c.—A. G. L.

Paper or Cardboard; Casein Sizing of —. F. Dobler. Fr. Pat. 350,035, July 4, 1904.

THE sheets or webs of paper, after their formation, are passed through a bath containing a solution of casein and then through a second bath containing a solution of aluminium sulphate or other precipitating agent. If desired, substances like starch, gelatin or rosin may be mixed with the casein solution.—J. F. B.

Papers; Impt. of the Baths used for Manufacture of Coated —. L. F. J. L. Aubertin. Fr. Pat. 353,033, April 5, 1905.

A CHLORIDE, such as barium chloride or the chloride of an alkali metal, preferably common salt, is added to the coating composition in order to minimise the frothing and to increase the flexibility and brilliancy of the coating. With gelatin compositions 7–8 per cent. of the dry weight of the gelatin is employed; with casein compositions 5–6 per cent.—J. F. B.

Casein; New Method of Preparing —. J. T. Gateau. Fr. Pat. 352,531, March 20, 1905.

BLUE milk is subjected to electrolysis in such a manner that the positive electrode is in the milk and the negative electrode is in a porous pot containing an alkaline conducting liquid. Under the action of the current, phosphoric acid is liberated in the milk from the phosphates contained therein, the casein is precipitated and the alkaline solution in the porous pot becomes enriched in alkali.—J. F. B.

Waste Waters of Paper Mills; Recovery of Residual Matters from, and Clarification of —. M. Erfurt. Fr. Pat. 352,524, March 20, 1905.

THE overflow from the paper machine is passed through a series of funnel-shaped vessels each one slightly larger than the preceding one, and arranged in steps. The sedimentary portion of the contents of the funnels is withdrawn for the purpose of filling and emptying the beaters and diluting the pulp; the overflow from the last funnel is finally clarified in a large tank and the clear liquid is discharged into a stream.—J. F. B.

Celluloid; Manufacture of — by means of Boric Acids. A. Béhal, P. Magnier and C. Tissier. Fr. Pat. 349,970, June 7, 1904.

SEE Eng. Pat. 11,512 of 1905; this J., 1905, 855.—J. F. B.

Celluloid; Process of Making Non-Inflammable Materials similar to —. P. A. D. Prost and E. Miché. First Addition, dated March 18, 1905, to Fr. Pat. 351,555, Jan. 17, 1905. (See this J., 1905, 855.)

THE following substances are added to the mixture described in the principal patent:—Fused zinc chloride (in alcohol solution), 10 to 25 per cent.; ammonium chloride (in alcohol solution), 1 to 5 per cent.; carbon tetrachloride, 1 to 15 per mille; glycerin, 5 to 10 per cent.—T. F. B.

Celluloid; Manufacture of —. C. Gillet. Fr. Pat. 352,853, March 30, 1905.

IN the manufacture of celluloid, the whole or a portion of the camphor is replaced by an equal quantity of rosin

or other resinous material equally soluble in alcohol. The process of manufacture is the same as is usually employed.—J. F. B.

Lacquers or Varnish; Process for the Manufacture of —. L. Lederer. Fr. Pat. 352,897, April 1, 1905. X. B., page 978.

Gases Heavier than Air; Process for the Recovery of, obtained from every Volatile Liquids. C. and M. Libt. Fr. Pat. 352,298, March 11, 1905. Under Int. v., Jan. 27, 1905.

THE process is intended for the recovery of vapours heavier than air, such as carbon bisulphide or vapour, for example, in the manufacture of celluloid, smokeless powder, &c. The chambers in the vapours are present are provided with troughs perforated false bottoms, the spaces between the troughs being connected with a pump; these troughs are situated at the bottom of the chambers, so that the vapour collected in them and drawn off, whence they are introduced into a condensing liquid through perforated pipes, the liquid being cooled if necessary.—T. F. B.

XX.—FINE CHEMICALS, ALKALOID ESSENCES, AND EXTRACTS.

Cyanogenic Glucosides of the Cherry-Laurel and Cherry. K. Jouek. Archiv Pharm., 1905, 243, 1-426.

THE bark of the wild cherry (*Prunus padus* L.) was found to contain about 0.5 per cent. of glucoside, which was to consist of an amorphous yellow substance, very hygroscopic, easily soluble in water and alcohol, but insoluble in ether, light petroleum and ethyl acetate. It decomposed at 60°–70° and smells of benzaldehyde at 130° C. Analysis shows the formula to be $C_{45}H_{68}N_2O_{23}$, or $C_{45}H_{68}N_2O_{22}$; it yielded 6.05 per cent. of hydrocyanic acid and 1.88 per cent. of dextrose. A barium salt $C_{25}H_{40}O_{11}$ or $C_{25}H_{40}O_{10}Ba$ was prepared. The leaves of the laurel (*Prunus laurocerasus* L.) yielded 0.8 per cent. of a yellowish, amorphous glucoside, which deliquesces and turned brown in the air. It is easily soluble in water and alcohol, insoluble in ether, light petroleum or ethyl acetate. It yielded 2.75 per cent. of hydrocyanic acid, and 2.7 per cent. of dextrose. By alkaline hydrolysis a crystalline barium salt was produced.—F. S.

Citral in Lemon Oil; [Determination of —] G. Romeé. XXIII., page 988.

ENGLISH PATENTS.

UNITED STATES PATENTS.

Urea; Process of Making —. H. Foersterling and Philipp, Perth Amboy, Assignors to The Roessler and Hasslacher Chemical Co., New York. U.S. Pat. 7913, Aug. 8, 1905.

CYANAMIDE salts (such as disodium cyanamide) are added to excess of mineral acid (e.g., sulphuric acid) to form cyanamide, which is then converted into urea by heating its sulphuric acid solution.—T. F. B.

doxyacetylurea and Process of Making Same. — F. C. Emmensen and A. H. C. Heitmann, Assignors to Park & Davis and Co., Detroit. U.S. Pat. 797,792, Aug. 22, 1905.

yl derivatives of hydroxyacetic acid are condensed with urea to form alkylhydroxyacetylureas. Thus, diethylhydroxydiacetylurea,

is produced by condensing a diethylhydroxyacetic acid with urea by means of an alkali alcoholate. It is a solid of sp. gr. 1.1107, having a slightly ethered odor; its b. pt. at 36 mm. is 186° C.; it is soluble in 20 parts of water, forms crystalline salts with alkalis, and is easily soluble in organic solvents. — T. F. B.

ol Esters [Ethers]; Process of Making — J. F. Larre, Assignor to E. I. Du Pont De Nemours Powder Co., Wilmington. U.S. Pat. 797,024, Aug. 15, 1905.

col ethers are prepared by passing a halogen derivative of the necessary hydrocarbon into an alcoholic solution of an alkali phenolate. For instance, anisol is produced by passing methyl chloride into sodium phenolate in alcoholic solution. — T. F. B.

FRENCH PATENTS.

phor; Synthetic Process of Preparing — A. Chal, P. Magnier and C. Tissier. First Addition, dated May 16, 1904, to Fr. Pat. 349,886, May 5, 1904.

conducting the reaction described in the original patent (this J., 1905, 857) in an autoclave, heated to about 100° C., it is possible to reduce by half the quantity of acetic acid used. Much of the acetic acid may be removed from the distilled solution (*loc. cit.*) by cooling to 0° C., when it crystallises out. The camphene in acetic acid solution is found to be converted into bornyl and isobornyl esters by adding a small quantity of sulphuric acid. A mixture of borneols obtained by saponifying the mixed esters is conveniently purified by passing steam through which removes the oily impurities, but very little of borneols. The camphene may be easily and advantageously oxidised to camphor by means of potassium permanganate in acetone solution, or in presence of ethyl acetate. Borneol mixture may be oxidised by the same process, acetone being distilled off after the reaction, and steam driven through the residue. — T. F. B.

phor from Isoborneol; Process of Preparing — F. Boehringer and Soehne. Fr. Pat. 352,888, March 31, 1905. Under Int. Conv., May 20, 1904.

Eng. Pat. 28,035 of 1904; this J., 1905, 249. — T. F. B.

phor from Borneol and Isoborneol; Process of Preparing — Chem. Fabr. auf Actien, vorm. E. Schering. Fr. Pat. 353,065, April 5, 1905. Under Int. Conv., April 27, 1904.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Emulsions; Silver Phosphate — Valenta, P. O. Kott. Through Phot. Mitt., 1905, 42, 250-251.

SATISFACTORY silver phosphate emulsions are obtainable by adding ammoniacal silver nitrate solution to 1500 c.c. of 3 per cent. collodion, to which is added a solution of 20 c.c. of 20 per cent. phosphoric acid and 60 grms. of citric acid in 100 c.c. of alcohol. The ammoniacal silver nitrate solution is obtained by adding sufficient "880" ammonia to 60 grms. of silver nitrate to obtain a clear solution, and then adding 250 c.c. of absolute alcohol. 250 c.c. of ether are added to the emulsion, which is then filtered. — T. F. B.

Bichromate [Sensitising] Mixtures; Increase in Sensitiveness of — by the Addition of Different Dyestuffs. H. Cahnels and L. P. Clerc. Monit. de la Phot. Through Phot. J., 1905, 45, 309-311.

THE increase in sensitiveness of bichromated gelatin and albumin mixtures (such as are used for ornamenting metal plates) is not proportional to the quantity of dyestuff added (in the case of Erythrosin and Eosin), but attains a maximum; e.g., in the case of Erythrosin and a "gelatin enamel" mixture, the maximum is reached with 2 grms. of Erythrosin per litre of enamel solution (one part to 30 parts of ammonium bichromate). Beyond this maximum, the sensitiveness rapidly decreases. Gradation is found to be better rendered as the sensitiveness is increased. No other dyestuffs were found to be of such value as the two above mentioned; Acridine Orange, and the Ethyl- and Methyl Violets were found to have no useful action. — T. F. B.

Development; Physical —, of "Printing Out" Papers. Schmidt. Phot. Kunst. Through Brit. J. Phot., 1905, 52, 646-648.

NUMEROUS details are given of the results obtained by the "physical" development of "printing-out" papers with pyrogallol, quinol and Metol; a variety of tones is stated to be produced by the addition to the developer of various organic acids, phosphoric acid, potassium bichromate, acetone, copper salts, &c. — T. F. B.

Intensification with Chromium and Iodine. C. W. Piper and D. J. Carnegie. Phot. J., 1905, 45, 306-307.

THE intensification produced in a negative by bleaching with bichromate and hydrochloric acid and redevelopment is found to be due to a compound probably identical with chromium tetroxide, produced by the reduction of the chlorochromate by the metallic silver. The bleaching solution recommended consists of potassium bichromate, 10 grs.; hydrochloric acid (sp. gr. 1.16), 5 minims; water, 1 oz.; this is less strongly acid than that recommended by Eder, and gives greater intensification. If a large excess of acid is used, chlorine is generated, and re-exposure is necessary before development; otherwise the silver chloride produced develops readily without exposure. Amide with sodium sulphite is recommended for redevelopment, as the process may then be safely and advantageously repeated.

Intensification with iodine is useful in cases where the negative is not excessively "thin"; the negative is bleached in a solution of potassium iodide, $7\frac{1}{2}$ grs.; iodine, 15 grs.; water, 2 oz.; rinsed and immersed for a short time in a quinol-soda developer; the plate is then exposed, on both sides, to the light of burning magnesium, and again immersed in the developer, when intensification results; it is found to be due to enlargement of the grains; the image contains considerable quantities of unreduced silver iodide, 25 to 40 per cent. of the total silver being present as iodide. — T. F. B.

Sodium Hydrosulphite; Alteration and Preservation of Anhydrous — in Powder, and in Aqueous Solution. Lumière and Seyewetz. VII., page 965.

FRENCH PATENT.

Photographs: Process for Producing Pigment, Monochrome, or Polychrome, or Natural Colour ——. and *Plastic Printing Plates, by means of a Silver Salt or similar Emulsion*. J. Meszáros. Fr. Pat. 352,815, March 30, 1905.

A PHOTOGRAPHIC negative, obtained in the ordinary manner, is immersed for from three to five minutes in a solution of an alkali bichromate, and is then transferred to a bath which will dissolve out the silver, and, at the same time, permit the precipitation of silver chromate on the gelatin; a 2 or 3 per cent. solution of nitric acid is stated to serve this purpose. The negative is now immersed in hot water, and the chromate removed from it by any suitable method, e.g., by means of nitric acid, whereby a gelatin relief negative results; this may be coloured with a pigment, and the resulting plate used for printing purposes, or it may be employed in the usual manner for the preparation of positive photographs. Plates, films, and papers containing the necessary pigment (which is insoluble in the various reagents used) are also claimed.

—T. F. B.

XXII.—EXPLOSIVES, MATCHES, Etc.

Explosion of Fireworks: Circumstances attending an ——. which occurred at the *Factory of Messrs. John Jennison and Co., at Belle Vue, near Manchester, in the County of Lancashire, on July 9, 1905*. By Major A. Cooper Key, H.M. Inspector of Explosives.

WHILE workmen were engaged with copper funnel and drift in stemming fireworks composition into cardboard cylinders to form "lances," one of these burst into flames, and 30 lb. of explosive in the building were also involved. The composition in question consisted of potassium chlorate, copper oxychloride, rosin, potassium nitrate, and arsenic sulphide. This composition is extremely sensitive to percussion and friction, and it is considered that a blow between the two copper implements used might well suffice to raise a thin film of powder to the ignition point, although having regard to the rareness of such accidents, it is, perhaps, more probable that a particle of grit was present. Experiments showed that the composition in question will fire when rubbed between two wooden surfaces even when the ingredients are of the best quality, and it is considered desirable that the smallest possible quantity of explosive should be present in any building in which the somewhat rough and ready operation of filling "lances" is in progress. Attention is drawn to the value of unflammable clothing, and also the provision of adequate means of escape from danger buildings, and a suggestion is made that the sleeves of the working dress should not be turned up in a danger building.—G. W. McD.

Explosives in Coal Mines Order: Aug. 4, 1905 ——. A. Akers-Douglas, one of H.M. Principal Secretaries of State.

THE following have been added to the list of "Permitted Explosives":—

Kynite Condensed:—Consisting of nitroglycerin (24—26

parts), wood meal dried at 100° C. (2.5—3.5 parts), starch dried at 100° C. (32.5—35.0 parts), barium nitrate (31.34.5 parts), calcium carbonate (0.0—0.5 part), and moisture (3.2—6.0 parts). The explosive shall be only when contained in a non-waterproof wrapper of parchment paper, and with an electric detonator of not less strength than No. 6.

Recite:—Consisting of nitroglycerin (6.5—8.5 parts), ammonium nitrate (64—68 parts), sodium nitrate (16 parts), trinitrotoluene (6.5—8.5 parts), wood meal dried at 100° C. (3—5 parts) and moisture (0.5—1.5 parts).

The explosive shall only be used when contained in stout paper case thoroughly waterproofed with cement and resin, and with an electric detonator of not less strength than No. 6.

Withnell Powder:—Consisting of ammonium nitrate (88—92 parts), trinitrotoluene (4—6 parts), flour (4 at 100° C. 4—6 parts) and moisture (0.0—1.5 parts). The explosive is to be used only when contained in a case of linen paper thoroughly waterproofed with a mixture of carnauba and paraffin waxes, and with an electric detonator of not less strength than No. 7.—G. W. McD.

ENGLISH PATENTS.

Explosive Compositions: Manufacture of ——. H. F. London. Eng. Pat. 17,880, Aug. 17, 1904.

SEE Fr. Pat. 346,135 of 1904; this J., 1905, 105.—T.F.B.

Cordite: Manufacture of ——. L. Le Brocqy, Du. Eng. Pat. 18,269, Aug. 23, 1904.

CLAIM is made for the employment, in the manufacture of cordite, of a pure or refined hydrocarbon oil or such as "white mineral jelly" or *paraffinum liquidum* with or without the addition of paraffin wax or ceresin or both, in place of the "semi-crude mineral jelly" usually employed. The deterioration which cordite suffers exposure to heat and light or by mere storage for a long time is stated to be due to the fact that the "semi-crude mineral jelly" employed in its manufacture becomes partially nitrated owing to its content of olefines and naphthenes.—A. S.

Nitroglycerin: Manufacture of ——. A. Mikolajczak, Castrop, Germany. Eng. Pat. 27,706, Dec. 19, 1904.

SEE Fr. Pat. 349,078 of 1904; this J., 1905, 636.—T.F.B.

Explosives [Chlorate]: Manufacture of ——. L. Thevenet, Paris. Eng. Pat. 8746, April 25, 1905. Under Int. Conv., Dec. 12, 1904.

A GRANULAR explosive is produced by incorporating potassium chlorate (75 parts), with molten dinitrotoluene (25 parts), allowing the mass to cool and sifting to the required size of grain. To produce a plastic explosive, nitrocellulose (2 parts), is gelatinised with melted dinitrotoluene (25 parts), and potassium chlorate (75 parts) is then added. The use of perchlorates is also claimed.—G. W. McD.

Explosive Materials and Propellant Compositions; Process for Manufacture of —. Westfälisch-Anhaltische Sprengstoff A.-G. Fr. Pat. 352,750, March 27, 1905.

hydrochloric acid gas be passed into glycerin, heated between 70° and 100° C., rapid absorption takes place with the formation of monochlorhydrin. If the oil be then distilled, *in vacuo*, the monochlorhydrin escapes over between 135°–160° C. By the action of concentrated acid it is converted into dinitromonochlorhydrin, proposed to use this body in explosives, in place of glycerin, either wholly or in part. The compound can be manufactured without danger, and is more stable—less sensitive to shock than nitroglycerin. It does not freeze at low temperatures and has a strong gelatinising effect on nitrocellulose, &c. Increased safety in the manufacture of nitroglycerin is said to be obtained by adding to the glycerin before nitration a certain proportion of monochlorhydrin.—G. W. McD.

Gas Heavier than Air; Process for the Recovery of —. Obtained from very Volatile Liquids, C. and M. Liebrecht. Fr. Pat. 352,298, March 11, 1905. XIX., page 984.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS, Etc

UNITED STATES PATENTS.

Oil Tester. F. A. Courtois, Newark, N.J. Assignor to Fiske Bros. Refining Co., New York. U.S. Pat. 8,250, April 25, 1905.

Fig. 2

The annular stand 1 is mounted on legs provided with levelling screws. It supports a movable frame 5, which receives heat from a Bunsen burner, or the like, attached to a leg of the stand. The test cup 7, (see Fig. 1, and see also Fig. 2) rests on lugs 10 on the frame, and is fitted with an overflow trough 9 to receive any oil that overflows by expansion, whilst the open spaces between the lugs form draught ports for the heating flame. An outer ring 11 on the cup has a dove-tailed recess 11^a to hold a lifting handle (see Fig. 2). The test flame device consists of a gas-burner tip 11 mounted so as to project just above the top of the cup, by means of a block 15, which slides up and down a vertical rod 17 attached to one of the legs of the stand, the whole being arranged so that the test flame passes in a nearly horizontal direction over the surface of the oil in the cup. The temperature of the oil is measured by a thermometer 20, suspended from an adjustable rod mounted on a leg of the stand; and the rate of heating is controlled by adjusting the height of the main burner on its support.—C. S.

Viscosimeter. F. A. Courtois, Newark, N.J. Assignor to Fiske Bros. Refining Co., New York. U.S. Pat. 788,251, April 25, 1905.

The main features of the invention are:—An oil bath 5, with a vertical central tube 6 open at the bottom; a testing cup 7 inserted into the tube 6, and provided at the upper end with an overflow trough 8, whilst the lower end contains an outflow orifice 9, which is normally closed by a needle-valve 10; a spider 12 loosely seated on the upper edge of the trough 8 and carrying a sleeve 11 which guides the stem of the needle-valve and is slotted to receive a pin 14 on the said stem when the latter is in position for closing the outlet orifice, the pin being rested on the upper edge of the sleeve when the orifice is to be kept open; thermometers 15 and 20 dipping into

the test cup and oil bath respectively and suspended from adjustable supports mounted on the edge of the bath; also an annular stand, mounted on legs, fitted with levelling screws and supporting a heating burner.—C. S.

INORGANIC—QUANTITATIVE.

Ferrous Iron; Titration of —, with Permanganate, in Presence of Hydrochloric Acid. G. P. Baxter and H. L. Frevert. *Amer. Chem. J.*, 1905, **34**, 109–117.

FERROUS chloride solution was prepared containing enough hydrochloric acid for the conversion of the ferrous to ferric salt, and quantities of this containing 0.25 grm. of FeCl_2 , diluted to 150 c.c., were titrated with potassium permanganate. Excess of permanganate over the theoretical amount was always necessary, but the excess lessened with rise of temperature from 1.0 per cent. at 30° to 0.3 per cent. at 80–85° C. At the latter temperature, dilution (between the limits of 50 and 300 c.c.) had no influence. Addition of hydrochloric acid, up to 40 c.c. of acid of sp. gr. 1.05, was almost without influence, but tended to lessen the excess of permanganate needed. Addition of 0.5 grm. of manganous chloride was insufficient to eliminate the error save at 95–97° C., but 1 grm. of the salt, or 0.5 grm. of manganous sulphate, made the titration accurate at all temperatures. The error appears to be due to the formation, not of chlorine, but of hypochlorous acid; and the effect of the manganous salt is due to its reaction with the permanganate, and the formation of tervalent or tetravalent manganese compounds, which react on the ferrous salt, these successive reactions occurring more rapidly than that of the permanganate upon hydrochloric acid. (See also this *J.*, 1905, 639.)

—J. T. D.

Silicon in Steel; Rapid Process for the Determination of —. H. Rubrichus. *Stahl u. Eisen*, 1905, **25**, 1012–1013.

FIVE grms. of steel cuttings are dissolved in 40 c.c. of dilute (1:2) sulphuric acid warmed to 50–60° C. in a beaker of 300–400 c.c. capacity. After the first violent evolution of gas has ceased, the walls of the beaker are rinsed with a very small quantity of water, and the beaker is heated over wire gauze until practically the whole of the water is expelled. Under these conditions, ferrous sulphate separates in the form of a voluminous mass, and the mixture can be boiled without any danger of spitting or bumping. If the cuttings have not completely dissolved, further successive additions of small quantities (not sufficient to dissolve the separated ferrous sulphate) of water (or of nitric acid) are made, and the mixture boiled after each addition. The residue of ferrous sulphate, &c., and sulphuric acid is cooled, diluted with 100 c.c. of water, a few c.c. of hydrochloric acid added, and the whole heated to boiling. The solution is then diluted to about 200 c.c., filtered, and the residue of carbon and silica washed with hot water, hot dilute hydrochloric acid, and again with hot water. The filter is then incinerated, the ash and residue ignited, and the pure silica weighed. It is stated that if the prescribed conditions be adhered to, the results obtained agree well with those obtained by other methods of determining silicon employed in metallurgical laboratories.—A. S.

ORGANIC—QUANTITATIVE.

Thiophen; Colorimetric Determination of —. C. Schwaibe. *Chem.-Zeit.*, 1905, **29**, 895–896.

THE methods hitherto introduced for the quantitative estimation of thiophen in benzene being more or less unsatisfactory, the author has devised a colorimetric method based upon the isatin reaction. It is simple and rapid in execution, capable of detecting differences of 0.02 per cent. and perfectly trustworthy within the limits of 0.5 per cent. and 0.05 per cent., which are said to be the maximum and minimum proportions of thiophen found in commercial benzols. The requisite solutions are:—A number of test solutions of benzene containing the following percentages of thiophen:—0.5, 0.25, 0.1, 0.075, 0.05, 0.025, and 0.01. A solution of 0.5 grm. of isatin in 1000 grms. of pure concentrated sulphuric acid. Two

100 c.c. measures are each charged with 25 c.c. of isatin solution and 25 c.c. of pure concentrated sulphuric acid. To one of the measures 1 c.c. of one of the thiophen test solutions is added, and to the other 1 c.c. of the benzol test solution is added. Both solutions are then shaken for minutes and the colours viewed on a white base.—D. J.

Citral in Lemon Oil; [Determination of —]. G. Rochem. and Druggist, 1905, **77**, 408.

THE method proposed by the author for the determination of citral in lemon oil, or other mixtures containing it, is based upon the fact that if citral be absorbed by a solution of potassium sulphite or sodium bisulphite containing sufficient excess of the acid sulphite for the liquid to remain acid after the absorption, the acidity is diminished in the proportion of three mols. for each molecule of citral. The sulphite solution is prepared by dissolving 400 g. of crystallised sodium sulphite in one litre of water, adding a sufficient quantity of a saturated solution of sodium bisulphite to make 25 c.c. of the mixed solution capable of neutralising about 20 c.c. of N/2 caustic potash solution. The solution is then heated in a closed vessel on the water-bath for three hours, and its acidity determined. In making a determination, 5 grms. of lemon are neutralised, if necessary, by a drop or two of weak alkali, using rosolic acid as indicator, and are heated with the sulphite solution in a closed vessel on the water-bath for 45 minutes, and the acidity of the solution determined. The percentage of citral is calculated by the

formula: $P = \frac{D \times 5.066}{x}$, where D is the decrease of acidity in c.c. of N/1 acid, and x the weight of lemon oil. Samples of lemon oil were found to contain 3.64, 4.48, and 3.80 per cent. respectively of citral.—A. S.

ERRATUM.—This *J.*, 1905, page 692, col. 2, line 24 from bottom. For *green* read *yellow*.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Liquids of High Specific Gravity; Use of Alkali Mercuric Iodides for —. Duboin. *Comptes Rendus*, 1905, **141**, 385–388.

THE author prepared solutions of high specific gravity by dissolving the alkali iodide and the mercuric iodide separately in a small quantity of water, till no more of the substances were taken up. The liquid was weighed slightly and filtered after standing for 24 hours. The densities at 26° C. and refractive indices for the sodium flame of the following solutions were determined: 1. Sodium mercuric iodide (Thoulet's liquid), sp. gr., 3.6; $n_D = 1.730$. Sodium mercuric iodide: sp. gr., 3.46; 1.797. Lithium mercuric iodide: sp. gr., 3.28; $n_D = 1.797$. Ammonium mercuric iodide: sp. gr., 2.98; $n_D = 1.797$. The sodium solution cannot be diluted with water, it dissolves without decomposition in alcohol and other organic liquids. It causes filter paper to thicken and become gelatinous.—F. S.

Solids; Flow of —. A. von Obermayer, G. Tammer, N. Werigin and J. Lewkojew. *Beiblätter, Annalen der Physik*, Leipzig, 1905, **29**, 6. *Proc. Inst. Civil Engineers*, 1905, **160**, 65.

ICE, camphor, clay, paraffin wax, beeswax, and candle all showed disc or scale structures after being pressed through a hole in a steel cylinder. The discharge formed conglomerating grains of about $\frac{1}{2}$ in. diameter. For ice and paraffin wax, the efflux velocity was found to be nearly proportional to the cube of the pressure. The speeds of flow of potassium, sodium, lead, thallium, bismuth, cadmium, zinc and antimony at constant pressures and at temperatures of from 212° to 356° F. (100°–180° C.) were in the order given. Zinc did not flow until a pressure of 30,000 lb. per sq. in. was applied, whilst antimony showed no movement under a pressure of 45,000 lb. per sq. in. and a temperature of 481° (249° C.). In general, the rate of flow of the metals doubled for an increase of temperature of 18° F. (10° C.). At 392° F. (200° C.) the rate of flow of lead was markedly reduced, whereas thallium showed a distinct softening at 356° F. (180° C.).—A. S.

OTHER FOR LIBRARIES. By E. W. HULME, J. GORDON PARKER, A. SEYMOUR-JONES, CYRIL DAVENPORT and J. WILLIAMSON. The Library Supply Co. Published for the Sound Leather Committee of the Library Association, Bridge House, 181, Queen Victoria Street, London, E.C. 1905. Price 1s. 6d. nett.

AY 8vo. volume containing 54 pages of subject matter and an alphabetical index. The subject matter is divided into five chapters, and is the work of five authors. I. History of Smack Tanning in England, Degradation of Manufacture of Leather, and History of the Reform Movement (E. W. Hulme). II. Causes of Decay in Book-binding Leathers (J. Gordon Parker). III. Provenance, Characteristics and Values of Modern Bookbinding Leathers (A. Seymour-Jones). IV. Repairing and Binding Books for Public Libraries (Cyril Davenport). V. Classification for the Fittings of a Small Bindery (F. J. Williamson). The work is illustrated with six specimens of authors.

SUGAR AND THE SUGAR CANE: AN ELEMENTARY TREATISE ON THE AGRICULTURE OF THE SUGAR CANE AND ON THE MANUFACTURE OF CANE SUGAR. By NOEL DEERR, Norman Rodger, Altrincham, Manchester. 1905. Price 7s. 6d. nett.

A volume containing preface, bibliography, and 392 pages of subject matter, with an appendix of three pages and an addendum (one page), and the alphabetical index subjects. There are 130 illustrations and nine coloured plates. The subject matter is subdivided as follows:— I. The Cane. II. Range of Soils and Climate suited for the Cane. III. Varieties of Sugar Cane. IV-VII. Its Cultivation, Irrigation, Manuring and Diseases and Insects. VIII. Transport, Harvesting and Unloading of the Cane. IX. Extraction of Juice by Mills. X. Juicing Process. XI. Clarification or Defecation of Juice. XII. Carbonation Process. XIII-XV. Evaporation of Juice; Its Evaporation to Syrup, and Concentration to Massecuite. XVI. Separation of Crystals from Massecuite. XVII. Crystallisation in Motion Process. XVIII. Molasses, and Geerlig's Theory, &c. XIX. Distillation as Fuel. XX. Control of the Factory. XXI. Polariscope. XXII. Determination of Glucose. XXIII. Analysis of Sugar-House Products. XXIV. Conclusions in reference to the Sugar-House.

Trade Report.

I.—GENERAL.

PATENTS ACT, 1902, AND THE PATENTS RULES, 1905: THE —.

The memorial which Sir Lloyd Wise presented to the President of the Board of Trade in March last praying for certain amendments to be made in the new Patents Rules, together with the counter-memorial, signed by 76 interested patent agents, urging that the amendment would be harmful, has now received the consideration of the Board of Trade. The following is a copy of the letter communicating the decision:—

Board of Trade (Finance and General Department), 7, Whitehall-gardens, London, S.W., Aug. 14, 1905. Fifth Brewer, Esq., 33, Chancery-lane, W.C. Sir,—I am directed by the Board of Trade to refer to your letter of April 1 last addressed to the President submitting a counter-memorial to the memorial presented by W. Lloyd Wise urging a modification of the Patents Rules, 1905, and, in reply, to state for the information of counter-memorialists that the Board of Trade have

consulted the law officers of the Crown in the matter, and have been advised by them that in their opinion there is no reason for making any alterations in the rules as they stand at present.

I am, Sir, your obedient servant,

WALTER J. HOWELL.

The following is the substance of the memorial referred to:—

As Rules 9 and 10 now stand, when the Comptroller determines that reference ought to be made in the applicant's specification to a prior specification or specifications by way of notice to the public, the form of reference must be as follows, and be inserted after the claims:—

"Reference has been directed, in pursuance of Section 1, Sub-section 6, of the Patents Act, 1902, to the following specification of Letters Patent No. granted to....."

Where the reference is inserted as the result of a provisional report under Rule 7, a statement to that effect must be added to the reference.

Such a reference will virtually make public the pith of the Examiners' Report, notwithstanding the enactment that Reports of Examiners shall not in any case be published or be open to public inspection (Sub-sec. 4 of Sec. 1 of 1902 Act, and Sub-sec. 5 of Sec. 9 of 1883 Act, as amended by 1888 Act). Moreover, although based upon mere opinion, which may be erroneous, it will usually render a patent commercially worthless. This is a very serious matter, seeing that, in the past, large manufacturing concerns, which have rendered public service by introducing articles of great utility not previously on the market, besides giving employment to many thousands of workmen and others, have accomplished these beneficial results under patents for inventions as to the novelty of which (in the patentable sense) expert and even judicial opinions have differed.

We, therefore, hope that it will be found possible to forthwith so modify the Rules as to obviate the unnecessary risk they at present involve of seriously retarding the introduction of improvements which, though individually of a minor character, do, in the aggregate (to quote the Select Committee of 1872), contribute greatly to the progress of industry. To this end, we venture to suggest revision in the sense that in no case shall either an official notification be endorsed upon, or a stereotyped form of reference be inserted in an applicant's specification, unless and until he shall have been notified of the Comptroller's determination, and shall have been afforded, and shall have failed to exercise, the option of himself inserting in his own specification a reference, by number, year and name (and not in a stereotyped form) to the prior specification (or specifications) reference to which the Comptroller shall have determined ought to be made in the applicant's specification by way of notice to the public.

We submit that the Act does not provide for Official insertion in, or endorsement upon an Applicant's specification of any notification; and, moreover, that, as the specification is addressed to the public, a reference in it to a prior specification or specifications, inserted by the applicant himself, would obviously constitute a notice thereof to, and would adequately protect the public, without necessarily injuring the applicant, as any official notification inevitably will.

Should it, however, be insisted that the modified procedure we recommend cannot be adopted as the law now stands, then regard being had to the importance of the interests involved, we trust His Majesty's Government will see fit to introduce a short Bill, in the coming session of Parliament, with a view of clearly legalising the proposed change in the Rules.

CAPE COLONY: TRADE OF —.

Ed of Trade J., Sept. 7, 1905.

The value of certain goods imported into and exported from Cape Colony during the six months ended the 30th June, 1905, as compared with the corresponding period of the preceding year, are as follows:—

*Imports into Cape Colony.**

Articles.	Six months ended 30th June.	
	1904	1905.
	£	£
Metals and metal manufactures (includes iron, lead, machinery, hardware, wire fencing, &c.)	1,391,000	1,009,000
Leather and leather manufactures (includes boots and shoes, and saddlery and harness)	403,000	482,000
Alcoholic beverages (includes wine, beer, and spirits)	194,000	182,000
Drugs and chemicals	134,000	130,000
Soap and candles	123,000	127,000
Oil, mineral	86,000	96,000
Coal, coke, and patent fuel	110,000	79,000
Arms and ammunition (includes dynamite and blasting compound and powder)	91,000	69,000
Earthen manufactures	56,000	52,000
Paints, varnish and turpentine	51,000	52,000
Cement	42,000	48,000
Oilman's stores (not edible)	33,000	38,000

* Exclusive of imports of diamonds and gold from South African States outside the Colony:—7,618,000*l.* during the first six months of 1904, and 10,485,000*l.* during the same period of 1905.

Exports from Cape Colony.

Articles.	Six months ended 30th June.	
	1904.	1905.
	£	£
Gold (raw)	7,539,000	10,053,000
Diamonds	2,479,000	2,641,000
Copper ore	254,000	290,000
Hides and skins	210,000	256,000

NATAL: TRADE OF —.

Bd. of Trade J., Sept. 7, 1905.

The following tables show the value of the import and export trade of Natal (by sea) in certain branches during

the six months ended 30th June, 1905, as compared with the corresponding period of 1904;—

Imports.

Articles.	Six months ended 30th June.	
	1904.	1905.
	£	£
Metals and manufactures of (includes agricultural implements, hardware, ironmongery, machinery, sewing machines, &c.)	709,000	724,000
Leather and manufactures (includes saddlery)	163,000	210,000
Beverages (includes ale, spirits, wine and aerated waters)	171,000	166,000
Oilman's stores (includes oils and paints)	117,000	101,000
Drugs and chemicals	85,000	75,000
Soap and candles	77,000	70,000
Glass and glassware	37,000	34,000
Cocoa, chocolate and confectionery	22,000	29,000
Arms and ammunition (includes blasting compounds)	22,000	26,000
Earthen, china and stoneware and marble	20,000	23,000
Floorcloth	21,000	23,000

Exports (Colonial Produce).

Articles.	Six months ended 30th June.	
	1904.	1905.
	£	£
Coal (bunker and cargo)	189,000	234,000
Bark	58,000	56,000
Sugar	29,000	40,000
Hides and skins	10,000	16,000
Matches	3,000	7,000

MEXICO; CUSTOMS TARIFF OF —.

Bd. of Trade J., Sept. 7 and 14, 1905.

The following is a further portion of the revised Customs Tariff for Mexico, which came into force on the 1st of (See this J., 1905, 908—9.):—

No.	Articles.	Unit.	Duty.
515	Aniline oils, natural or artificial alizarines, and anthracene	Kilo. gross	Pesos. 0 00
516	Acetates of alumina, ammonia, lime, copper, chrome, iron, lead, and soda	Kilo. legal	0 04
517	Arsenious acid	Kilo. legal	0 01
518	Sulphuric acid	—	Free

3	Printing ink, black	—	Free

in accordance with Article 3 of the Decree promulgating the new tariff, no additional duties are to be levied on imports over and above the duties specified in the tariff, except the 1½ or 2 per cent. tax levied by the Customs on behalf of the municipalities under the general Customs regulations, and (where necessary) the loading and unloading dues provided by the Decree of the 1st July, 1898. Regulations and provisions of law in conflict with the present Decree are abrogated, including especially:—

(1) The Decree of the 25th November, 1902, with reference to the method of calculating import duties;

(2) Article 106 of the Law of the 25th April, 1893, and Article 4 of the Law of the 4th May, 1895, imposing duties on foreign alcoholic and fermented beverages.

(3) Article 3 of the Decree of the 23rd February, 1897, fixing to 50 per cent., the import duties on iron pipes for the installation of urban water supply.

(4) Special exemptions accorded in favour of the iron industry and to imports into the Quintana Roo Territory are, however, maintained.

VII.—ACIDS, ALKALIS, Etc.
PHOSPHATE DISCOVERY IN JAPAN.
Bd. of Trade J., Sept. 7, 1905.

The July report of the Yokohama Chamber of Commerce states that a rich phosphate deposit has been discovered at Hammoura, Nanao Bay, Noto Province, and a merchant of Osaka has obtained a concession covering 3,000,000 *tsubo*.* The deposit extends under the sea, in a layer of 30 ft. The concessionaire intends to establish a factory at Nanao for manufacturing manure from the phosphorus.

XII.—FATS, FATTY OILS, Etc.
OIL SEEDS AND OIL CAKE: EXPORTS OF — FROM RUSSIA.
Chem. Trade J., Sept. 9, 1905.

The exports of oil cake from Odessa during the last three years were as follows:—

	1902.	1903.	1904.
	Tons.	Tons.	Tons.
United Kingdom	5,370	4,930	11,313
Belgium	7,510	3,930	7,005
Denmark	3,000	2,323	4,281
Germany	1,580	4,005	4,585
Netherlands	7,550	8,009	21,714
France	3,900	8,089	22,560
Other countries	1,530	702	209
Total	30,450	32,048	71,665

IA; ENFORCEMENT OF NEW "GENERAL" TARIFF DUTIES ON CERTAIN ARTICLES IN —.

Bd. of Trade J., Aug. 31, 1905.

Servian Royal *ukaz* has been issued putting into force the new Servian "General" Tariff duties on the articles enumerated in the following statement:—

Servian "General" Tariff No.	Articles.	Rate of Duty under the new "General" Tariff.
69	Fish fat: and fish oil, unrefined	Dinars.† Free.
(a) & (b) 97	Skins of domestic animals, raw, dried, wet, salted, limed or not, with or without the hair	Free.
	Wood and bark for tanning—	
	Quebracho and other wood and bark for tanning, in blocks or cut in pieces: algarovilla, bablach, gall nuts, dividivi, valonia, myrobalam, catechu, sumach, kino, and other materials for tanning not specially mentioned in the tariff	"
0 ex (2) 100 (1) ex 206 ex 207 ex 1 ex 2 ex 4) 1 ex (3) 4 ex (4) ex 225 ex (2) ex 230 7 ex (2)	Gum arabic (excluding liquid gum arabic) and adraganth	"
	Borax, crude, and boracic acid, crude	100 kilos. 10 00
	Bichromate of calcium	"
	Chrome-alum—	"
	Crystallised	" 2 50
	Calcined and powdered	" 15 00
	Sulphate of soda	" 0 50
	Hydrochloric acid	" 1 00
	Chromic acid	" 20 00
	Albumin —	"
	For technical purposes	" 35 00
	Barberry juice for tanning	Free
	" " dyeing	100 kilos. 10 00

* *Tsubo* = 3.9 square yards.

† Dinar = 9.6d.

The following comparative table shows the quantities of oil seeds exported in the last three years:—

	1902.	1903	1904.
	Tons.	Tons.	Tons.
Linseed	4,022	2,902	217
Hemp seed	3,170	1,501	250
Ravison	—	14,150	7,504
Mustard seed	100	31	133
Colza	187	—	588
Other oil seeds	3,773	536	87
Total	11,252	19,120	8,729

XVI.—SUGAR, STARCH, GUM, Etc.

SUGAR PRODUCTION OF AUSTRIA-HUNGARY.

For. Off. Ann. Series, No. 3486.

There were 7,780,000 tons of beetroot worked in the sugar mills of Austria-Hungary during the campaign of 1903-04 as against 7,130,000 tons in 1902-03. The number of mills working in 1903-04 was 215, producing 1,159,221 tons of raw sugar, as against 216 mills producing 1,051,264 tons in 1902-03.

The number of mills working in Bohemia in 1903-04 was 127, which produced 562,528 tons of raw sugar from 3,620,000 tons of beetroot, as against the same number of mills producing 440,225 tons from 2,860,000 tons of beetroot for the preceding campaign of 1902-03.

The total export from Austria-Hungary was:—

	Quantity.	
	1902-03.	1903-04.
	Tons.	Tons.
Raw sugar	108,505	55,444
Refined sugar	639,509	474,132
Equiv. in raw sugar	819,070	582,258

For the 1905-06 campaign there has been an increased area under sugar beet cultivation in Austria-Hungary on that of 1904-05 of about 12 per cent., and the outlook is favourable, pointing to a larger production of sugar than in previous years, and consequently the market price is falling in anticipation.

The percentage of sugar contained in the beet was:—

In—	1902-03.	1903-04.
	Per cent.	Per cent.
Bohemia	15.3	15.5
Austria	14.8	14.9

There were 236,652 tons of molasses produced in Austria-Hungary in 1903-04, of which 109,274 tons were produced in Bohemia. 172,553 tons were used in the distilleries, and the export was nil.

Patent List.

N.B.—In these lists, [A.] means "Application for Patent," and [C.S.] "Complete Specification Accepted."

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

- [A.] 17,815. Doulton and Hopkins. Furnaces. Sept. 4.
 „ 17,844. Weiss. Method of producing solid hard pieces from pulverulent material of any origin.* Sept. 4.

- [A.] 17,879. Brown and Brown. Separating organic materials melting at different temperatures apparatus therefor. Sept. 4.
 „ 17,933. Soddy. Method of producing vacuum. Sept. 5.
 „ 17,946. Clamond. Method and apparatus separating mixed gases. [Fr. Appl., Sept. 1904.]* Sept. 5.
 „ 18,130. Jürgens. Vacuum evaporating apparatus. Sept. 7.
 „ 18,172. Unglaub. Method and apparatus distilling and evaporating liquids in vacuum. Sept. 8.
 „ 18,444. Johansson. Centrifugal liquid separator. Sept. 12.
 „ 18,596. Reyscher. Drying apparatus. Sept. 12.
 „ 18,719. Oxford. Apparatus for drying semi-liquids. Sept. 16.
 [C.S.] 20,276 (1904). Aktiebolaget Separator. Centrifugal separators. Sept. 20.
 „ 24,670 (1904). Imray (Meister, Lucius und Leitz). Extraction of water or other liquid from mineral, vegetable and animal substances. Sept. 20.
 „ 1769 (1905). Wilkinson. Means for and method of carrying out secret manufacturing process by chemical treatment. Sept. 20.
 „ 3015 (1905). Suzuki. Furnaces. Sept. 13.
 „ 6876 (1905). Löffler and Weidle. Filters. Sept. 13.
 „ 7599 (1905). Bach. Manufacture of refractory furnaces. Sept. 20.
 „ 8984 (1905). Boulton (Goldman and Co.). Filtration apparatus. Sept. 13.
 „ 10,277 (1905). Bonnicart (Chapelle). Apparatus for filtering liquids. Sept. 20.
 „ 12,533 (1905). Barthelmeß. See under II.

II.—FUEL, GAS, AND LIGHT.

- [A.] 17,871. Lake (Gasglühlicht-Ges. Hameln). Incandescence bodies for incandescent gas lamps.* Sept. 4.
 „ 17,967. Gardam. Gas producers. Sept. 5.
 „ 18,004. Kennedy. Making producer gas and apparatus therefor. Sept. 6.
 „ 18,174. Ziegler. Kiln for the gasification or calcination of peat.* Sept. 8.
 „ 18,403. Siemens und Halske Akt.-Ges. Incandescence bodies of tantalum wire for electric lamps. [Ger. Appl., Oct. 13, 1904.]* Sept. 12.
 [C.S.] 24,400 (1904). Sutton and Rudd. Incandescent gas mantle. Sept. 20.
 „ 24,467 (1904). Kirkham, Hulett and Chatterfield Ltd., and Hersey. Apparatus for washing and scrubbing gas. Sept. 20.
 „ 24,489 (1904). Albane and Boswell. Means for vaporising heavy hydrocarbons. Sept. 13.
 „ 24,787 (1904). Spencer. Regenerative furnace for gas retorts and the like. Sept. 20.
 „ 563 (1905). Smyth. Plant for manufacturing acetylene. Sept. 20.
 „ 1307 (1905). Daniels, and Daniels, Ltd. Gas producers. Sept. 20.
 „ 1507 (1905). Lake (Cie. Gén. d'Electricité). Electrodes for arc lamps. Sept. 20.
 „ 1671 (1905). Kelly and Billington. Incandescent fuel. Sept. 13.
 „ 3174 (1905). Vedy and Bilbie. Gas producer apparatus and method of working same. Sept. 20.
 „ 7499 (1905). Thomas. Means for treating coal smoke for effecting its combustion. Sept. 20.
 „ 9001 (1905). Van Vriesland. Incandescent gas mantle. Sept. 13.
 „ 12,059 (1905). Moore and Livens. Gas producer. Sept. 13.
 „ 12,533 (1905). Barthelmeß. Method of and apparatus for purifying blast furnace gases, dust, air, &c., and for dissolving gases and matters in liquids. Sept. 13.

- [1.] 13,533 (1905). Carpenter. *See under* XXIII.
 16,050 (1905). Davis. Apparatus for generating gas from gasolene. Sept. 20.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

- [1.] 17,945. Boulton (Standard Oil Co.). *See under* XII.
 18,174. Ziegler. *See under* II.
 [1.] 23,984 (1904). Brunck. Extraction of ammonia from distillation gases. Sept. 13.

I.—COLOURING MATTERS AND DYESTUFFS.

- [1.] 18,196. Newton (Bayer and Co.). Manufacture of anthracene dyestuffs. Sept. 8.
 [1.] 24,669 (1904). Abel (Act.-Ges. f. Anilinfabr.). Manufacture of 1,6- or 1,7-arylnaphthylamine sulphonic acid. Sept. 20.
 25,889 (1904). Johnson (Badische Anilin und Soda Fabrik). Reduction of indigo and similar colouring matters. Sept. 13.
 26,457 (1904). Newton (Bayer and Co.). *See under* XIII.
 1368 (1905). Shillito (Geigy). Production of blue-black colouring matters. Sept. 20.

V.—PREPARING, BLEACHING, DYEING, DYEING AND FINISHING TEXTILES, YARNS, AND FIBRES.

- [1.] 17,915. Clegg. Method for printing certain effects on cotton. Sept. 5.
 17,960. Kelling. Machine for washing or dyeing carpets.* Sept. 5.
 18,168. Hulme. Apparatus for printing calicoes and other woven fabrics. Sept. 8.
 18,436. Pryor (Soc. Anon. Soieries Nouvelles de Bruxelles). Apparatus for washing threads or yarns of artificial silk or other material in the wound state. Sept. 12.
 [1.] 22,098 (1904). Davies. Production of ornamental patterns or effects on velvets, velveteens, &c. Sept. 20.
 25,296 (1904). Todtenhaupt. Preparation of artificial silk or hair. Sept. 20.
 6357 (1905). Linkmeyer. Devices for twisting and winding artificial threads. Sept. 20.
 7807 (1905). Delhotel. Apparatus for regaining the benzene employed for cleaning fabrics. Sept. 20.

—COLOURING WOOD, PAPER, LEATHER, ETC.

- [1.] 23,292 (1904). Lake (Chem.-Techn. Fabrik Dr. A. R. W. Brand and Co.). Colouring of stone. Sept. 20.
 16,316 (1905). Kornmann. Method of colouring wood. Sept. 13.

VII.—ACIDS, ALKALIS, AND SALTS.

- [1.] 17,886. Raschen, Wareing, and The United Alkali Co., Ltd. Treatment of gases obtained from arsenical sulphuric acid and other gas containing arsenious chloride and the obtainment of arsenious acid. Sept. 4.
 17,887. Raschen, Conroy, Wareing, and The United Alkali Co., Ltd. Treatment of arsenious chloride for the obtainment of arsenious acid. Sept. 4.
 18,141. Duke and Hubbard. Catalytic substance. Sept. 7.
 [1.] 23,036 (1904). Spence, and Spence and Sons, Ltd. Manufacture of aluminous compounds. Sept. 20.
 23,984 (1904). Brunck. *See under* III.

- [C.S.] 3820 (1905). Johnson (Foersterling and Philipp). Treatment of alkali peroxides for use in the obtainment of oxygen gas. Sept. 13.
 „ 6139 (1905). Wulze. Process for manufacturing lead carbonates. Sept. 20.
 „ 7616 (1905). Cornillaux. Extraction and purification of sulphur. Sept. 13.

VIII.—GLASS, POTTERY, AND ENAMELS.

- [A.] 17,890. Seiboldt. Process of treating alloxan. [U.S. Appl. Jan. 6, 1905.]* Sept. 1.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

- [A.] 17,847. Peters. Manufacture of Portland cement. Sept. 4.
 „ 18,722. Alexander and Wallis. Manufacture of bricks, tiles, and such like, from sand, slag, destructor clinker, &c., mixed with lime. Sept. 16.
 „ 18,725. Payne. Manufacture of silica fire bricks, crucibles, retorts, and the like. Sept. 16.
 [C.S.] 22,169 (1904). Perkin, and Whipp Bros. and Ted. Ltd. Treatment of wood for rendering it fire-proof. Sept. 20.
 „ 23,292 (1904). Lake (Chem.-Techn. Fabrik Dr. A. R. W. Brand and Co.). *See under* VI.
 „ 2343 (1905). Heintzel and Cramer. Method of improving gypsum mortar and utilising dead burnt gypsum. Sept. 20.
 „ 4693 (1905). Rogers. Method of applying pure mica as a covering for heat and cold. Sept. 20.

X.—METALLURGY.

- [A.] 17,839. Blackmore and Howard. Treatment of pyritic ores containing gold, silver, or other valuable metals. Sept. 4.
 „ 18,056. Steinhardt and Vogel. Treatment of tin ores. Sept. 6.
 „ 18,659. Abelspies. Ore dressing or concentrating tables. Sept. 15.
 [C.S.] 8808 (1905). Klepetko. Roasting furnaces. Sept. 20.
 „ 13,350 (1905). Langer. Apparatus for obtaining nickel from nickel carbonyl. Sept. 13.
 „ 13,613 (1905). Hobson. Silver alloys. Sept. 13.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

- [C.S.] 21,211 (1904). Kieseritzky. Method of regenerating negative accumulator plates of diminished capacity, or for avoiding the diminution in capacity of new plates. Sept. 13.
 „ 25,265 (1904). Boulton (Accumulatoren und Electricitäts Werke A.-G., vorm. W. A. Boese and Co.). Manufacture of accumulator electrodes. Sept. 20.
 „ 11,333 (1905). Luckow. Process of regenerating electric accumulators. Sept. 13.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

- [A.] 17,945. Boulton (Standard Oil Co.). Manufacture of composite paraffin wax candles.* Sept. 5.
 „ 17,999. Heys. Detergents and the manufacture thereof.* Sept. 6.
 „ 18,667. Bernard. Apparatus for extracting by means of carbon tetrachloride fatty substances from products containing the latter. [Fr. Appl., Dec. 24, 1904.]* Sept. 15.
 [C.S.] 24,023 (1904). Boardman. Manufacture of soap. Sept. 13.
 „ 1655 (1905). Bloom. Oil or fat compounds for edible and other purposes. Sept. 20.
 „ 10,326 (1905). Buchanan. Apparatus for heating and cooling linseed oil. Sept. 20.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

(A.)—PIGMENTS, PAINTS.

- [A.] 18,683. Milburn. Anti-corrosive paints or compounds. Sept. 15.
[C.S.] 26,457 (1904). Newton (Bayer und Co.). Manufacture of new colour lakes. Sept. 13.
.. 7750 (1905). Bell. Antifouling substances for ships. Sept. 13.

(B.)—RESINS, VARNISHES.

- [C.S.] 11,063 (1905). Menge. Priers for oils, paints, lacquers and the like. Sept. 13.

(C.)—INDIA-RUBBER.

- [C.S.] 21,899 (1904). Frost. Vulcanising apparatus. Sept. 20.
.. 24,691 (1904). Kite. Rubber vulcanising apparatus. Sept. 20.
.. 5965 (1905). Sine and Rosenthal. Material for the manufacture of rubber articles. Sept. 13.

XIV.—TANNING, LEATHER, GLUE, SIZE, Etc.

- [A.] 14,328. Thomas. Manufacture of casein compounds for films, sheets, and coatings. Sept. 11.
.. 14,338. Bögel. Process of and apparatus for the uninterrupted extraction of tanning substances.* Sept. 11.
.. 18,500. Smith. Apparatus for treating hides and leather. [U.S. Appl. Sept. 13, 1904.]* Sept. 13.
[C.S.] 23,619 (1904). Nottelle and Leroux. Method of treating corneous substances. Sept. 13.
.. 2441 (1905). Hunter. Process of treating bone. Sept. 13.
.. 12,266 (1905). Trenckmann. Manufacture of parchment-like skin. Sept. 20.

XV.—SUGAR, STARCH, GUM, Etc.

- [A.] 18,138. Monti. *See under XVII.*
[C.S.] 21,865 (1904). Hatmaker. *See under XVIII.A.*

XVII.—BREWING, WINES, SPIRITS, Etc.

- [A.] 18,138. Monti. Treatment of wine must, beer, beetroot juice and the like.* Sept. 7.
.. 18,351. House. The process of brewing. Sept. 11.
.. 18,393. Nycander. *See under XVIII.A.*
.. 18,658. Edwards (Pfaudler Co.). Process for fermenting beer, ale, and other fermentable liquids, and apparatus used in carrying out said process.* Sept. 15.
.. 18,748. Roche. Process of sterilising and preserving beers.* Sept. 16.
[C.S.] 10,198 (1905). Worssam. Apparatus for heating or boiling brewers' wort or the like. Sept. 13.

XVIII.—FOODS; SANITATION, WATER PURIFICATION; & DISINFECTANTS

(A.)—FOODS.

- [A.] 18,393. Nycander. Production of distillers' yeast from the raw materials for, and products, by-products, and residues from the manufacture of tapioca, sago, arrow-root, flour and like materials. Sept. 12.
[C.S.] 21,865 (1904). Hatmaker. Process of obtaining milk sugar and casein from milk. Sept. 13.
.. 23,616 (1904). Fulda. Preserving animal food substances. Sept. 13.
.. 24,430 (1904). Mitchell. Obtaining proteids. Sept. 13.
.. 1655 (1905). Bloom. *See under XII.*
.. 13,861 (1905). Kronheim. Substitute for coffee. Sept. 13.

(B.)—SANITATION; WATER PURIFICATION.

- [C.S.] 23,640 (1904). Spence, Spence, and Spence Sons, Ltd., and Ockel. Treatment of sewage and other similar sludges. Sept. 20.
.. 23,747 (1904). Bolton and Mills. Apparatus the automatic treatment of sewage or of impure fluid. Sept. 13.

(C.)—DISINFECTANTS.

- [C.S.] 4455 (1905). Fournier. Effecting the deodorisation of places or materials which have been disinfected with formaldehyde, or the like. Sept. 13.

XIX.—PAPER, PASTEBOARD, Etc.

- [C.S.] 24,083 (1904). Johnson (Badische Anilin und Soda Fabrik). Manufacture of acetyl cellulose. Sept. 13.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

- [A.] 17,850. Livingstone (Stein). Compound for use as medicine. Sept. 4.

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

SIXTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY, ROME, 1906.

The Sixth International Congress of Applied Chemistry will be held in Rome in April, 1906, during Easter week. All communications should be addressed to the President, Prof. E. Paternò, Via Panisperna, 89 Rome.

Changes of Address.

When notifying new addresses, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is also to be avoided as tending to create confusion. When sending subscriptions, the use of the form attached to the application helps in the verification of addresses, on which the safe delivery of the Journal depends.

Meeting held at Sydney on Wednesday, May 10th, 1906.

PROF. A. LIVERSIDGE, F.R.S., IN THE CHAIR.

THE MINERAL OIL FROM THE TORBANITE OF NEW SOUTH WALES.

JAMES M. PETRIE, D.Sc., F.I.C.

TORBANITE.

This organic mineral exists, as far as is known, in only three countries of the world, viz., at Torban Hill in Scotland, Antn in the centre of France, and in New South Wales. All occur in the carboniferous or permo-carboniferous epoch. The Scotch miners completely worked out between 1850 and 1872. The Torban shale has been worked since 1839, and the New South Wales shale since 1865. Its discovery was first recorded in 1807 in Paris by the members of a scientific expedition who visited Australia in 1802.

In the formation of torbanite, four factors are noted—(1) Humic compounds constituting the dark fundamental matter, precipitated from solution by inorganic substances in the water; (2) the gelatinous bodies of microscopic algæ, and their secreted spores and pollen grains, vegetable debris, and fossil ferns (the latter seldom occurring in the torbanite); no shells, bones, fish-scales or diatoms have been found; (4) dark brown bituminous matter derived through the mass, as a secondary and quite accidental infiltration.

Relation of Torbanite to other Bituminous Minerals.—The special characteristic of torbanite is the presence of the gelatinous algal bodies, which constitute 90 per cent of the total organic matter present; hence the ratio of volatile to fixed carbon in the mineral is high. Torban coal also contains algal cells in the humic precipitates; they are no longer the predominating matter in the coal.

avid has identified the alga in West Maitland (New South Wales) cannel coal as *Rhynchia australis*. Bituminous shale, the present oil-shale of Scotland, consists of the fundamental humic matter only, with various amounts of the secondary bituminous infiltrations. It contains numerous spores and pollen grains, and has a large proportion of mineral matter present. This shale includes the humic coals of Bertrand. Coals are specially characterised by the great accumulations of plants, stems and leaves, &c., preserved in the humic precipitate; they contain also immense numbers of spores.

Microscopic Structure of Torbanite.—As far back as 1853 there are records, in the *Journal of the Microscopical Society*, of attempts to solve the problem of the origin of torbanite. In the thin sections prepared from it transparent yellow bodies were recognised, which were long considered to be vegetable cells—spores, pollen grains, &c. In 1889, David recognised in these yellow bodies an intimate resemblance to certain lowly forms of algae like *Volvocineæ*—minute cœnobias inclosing many spores. Bertrand began in 1892 to make a complete microscopic study of the French torbanite, and in 1894 the New South Wales mineral also. His conclusions agree with those of David. Bertrand has named the alga the New South Wales torbanite *Rhynchia australis*, and at the Scotch and French torbanite *Pila*. I have succeeded in obtaining after great difficulty a number of thin microscopic sections of the torbanite, and have confirmed the presence of the algal cells. Drawings were made (800 diameters) showing complete cœnobias with numerous zoospores embedded in the gelatinous mass.

Composition of New South Wales Torbanite.—The following analysis of the richest Joadja Creek shale is given by W. A. Dixon:—C, 75.32; H, 12.05; O, 5.49; N, 0.28; S, 0.31; ash, 6.55 per cent. Pyrites is found in the shale and is probably the source of the sulphur. The ash has the following composition:—SiO₂, 77.12; Al₂O₃, 20.11; Fe₂O₃, 0.76; CaO, 0.30; MgO, 0.45; P₂O₅, 0.65 per cent. Anadic oxide has been found in the ash of New South Wales shale by Mingaye (Record Geol. Survey, New South Wales, 1903) to the extent of 0.01 per cent., and also the ash of Scotch shale as much as 0.12 per cent. has been shown to occur.

The ratio of volatile to fixed carbon in the richest torbanite of New South Wales is 16 to 1, and the ash 6 per cent., while in the torbanite of Scotland the ratio is 8 to 1, and the ash 20 per cent. The sp. gr. of the average New South Wales shale is 1.2, and of the richest shale 0.08.

Pure torbanite is distilled for oil in New South Wales only. In France it is used together with bituminous shales. The New South Wales mineral is also exported to Europe for distillation with cannel oil to enrich the ordinary coal gas. The gas is largely used on the Australian railways for illuminating purposes, as it can be compressed into cylinders without the condensation of any of its constituents taking place.

Natural Oil in Torbanite.—In order to discover whether any natural oil was present, some of the richest shale was crushed and pulverised till it passed through a 60-mesh sieve. It was agitated with benzene for three months by means of a hot-air motor. The solution, when separated, presented a deep yellow colour by transmitted light, right emerald-green by reflected light, and was highly fluorescent. The benzene was distilled off in a retort with a long rod-and-disk fractionating column, and, when reduced to a small volume, it was transferred to a test-tube and distilled to dryness. The following fractions were collected:—

B. pt., °C.	Vol.
79—85	600 c.c.=80 per cent.
85—90	35
90—100	25
100—110	60
110—115	20
115—130	10
130—150	4
150—170	0.5

Above 90° C. the fractions possessed a sharp acid sour, the last fraction was yellow, with an oily smell, and the residue above 170° was black and decomposed. It is evident that a molecular association takes place between

the oil and the benzene; the latter distils off between 80° and 150°, when the oil begins to decompose. Benzene, therefore, is an unsuitable solvent. The rest of the trials were done in the same way with pure dry ether as a solvent. The ethereal extract was separated, the residue washed till a colourless filtrate passed through, and the solution distilled. No odour of oil was perceived, and the whole of the ether distilled off within 1¹/₂ of its b. pt.; 3.73 grms. of oil were obtained from 1400 grms. of shale, the maximum extraction being 0.3 per cent. This does not, however, represent the whole of the oil in the shale, since, on further treating with boiling ether the supernatant liquid was still deep yellow, and by grinding the shale still finer more oil was again obtained.

The natural oil has the consistency of vaseline; its colour is reddish-brown with a dark green fluorescence by reflected light; it has a very slight odour. When heated gradually it begins to volatilise at 160° C., and immediately blackens and decomposes. On cooling it sets to a tough, rubber-like, odourless solid with a dark brown colour. A comparative experiment with vaseline under the same conditions showed incipient volatilisation and decomposition to take place almost simultaneously at a temperature of 260°, and on cooling the residue very much resembled in appearance the residue from the oil.

The oil solidifies at 30° C.; its b. pt. is about 160°; $d_{20}^{20}=0.9516$; ref. index at 20°, 1.5338. Concentrated sulphuric acid produces no blackening, and no smell, but after some time a faint dark brown colour is produced. The oil slowly chars when heated to the b. pt. of the acid. No additive compounds are formed on treatment with bromine; substitution derivatives are, however, formed, 100 grms of the oil taking up 7 grms. of bromine. On analysis, the oil gave the following result: C, 85.27 per cent.; H, 11.62; undetermined, 3.11 per cent., probably S, N, and O.

The natural oil in torbanite, therefore, consists of saturated hydrocarbons of high b. pt., along with a small quantity of other compounds of high sp. gr. and ref. index, and easily forming bromine substitution derivatives.

COMMERCIAL TREATMENT.

The best quality of torbanite is exported for gas-making, only the inferior qualities being treated for the manufacture of oils, paraffin wax, and ammonia. The following is a diagram of a typical section of the Hartley seams:—

Top, yielding 14 galls. of oil per ton

Intermediate, 60 galls. per ton.

Best export shale, yielding 150 galls. per ton.

Intermediate quality, 60 galls. per ton.

Bottom, 14 galls. per ton.

At the present time destructive distillation is carried on near Torbane only, beyond the Blue Mountains, about 130 miles from Sydney. The crude oil is conveyed by rail in tank waggons to the Hartley Vale refinery for further treatment. The crude oil is of a greenish-black colour, and solid (except in hot weather). It is treated first with sulphuric acid and then with caustic soda, giving a dark-green oil and much tar. On distilling the green oil four fractions are separated:—

Naphtha	3 per cent.	up to 0.790 sp. gr.
Solar oil	60	0.790—0.875
Heavy oil	17	0.875—0.920
Residue	20	above 0.920

termining the variation of the ratio of saturated to unsaturated hydrocarbons with the rise of boiling point. The properties of these distillates, after seven fractionations, are described and tabulated below:—

The figures in brackets are the boiling point of the isomeric forms. The specific gravities of the fractions are all very much higher than those of the pure normal paraffins, as is seen

Properties of the Naphtha Distillates—Fractions of 5'.

NOTE.—* Maximum or minimum values.

Properties of the Fractions.—The distillates up to 140° colourless: from 140° upwards the colour gradually passes to straw-yellow at 200°. On boiling for a short time, a colourless oil quickly turns yellow, and after a number of hours, dark brown. The first three fractions, lying between 30° and 60°, have a very distinct garlic odour, which is absent in all the others. All are optically active, and give no absorption spectra. In the tabulated results, regular periods are clearly seen. The paraffins (in last column) increase to No. 6, decrease to a minimum in No. 10, and gradually rise in to No. 12. In each period there is a recurrence of similar values, and these correspond to the theoretical boiling points of the paraffins. On referring to the tables of specific gravities and refractive constants the same facts of recurrence are noticed. These values are marked with asterisks in the table, and clearly indicate a concentration of the fractions in the neighbourhood of the normal paraffins.

The observations of the angles of refraction were made with a "Fuess" refractometer with sodium light, and at the same temperatures at which the specific gravities were determined. The specific refractive constants were calculated by the Lorenz-Lorentz formula. For comparison the critical values of the corresponding paraffins and olefines are calculated and shown in the following table:—

Formula.	Paraffins.	Olefines.	Boiling Points.
			Degs.
C_7H_{16}	0.34884	—	38, (30)
C_8H_{18}	—	0.35317	39 (36, 31)

$C_{10}H_{22}$	170°—175°	0.752
$C_{11}H_{24}$	195°—200°	0.765

The bromine absorptions show an average of 56 per cent. of paraffins between 70° and 185° b. pt.; at 200° the amount is 66 per cent., and from this temperature upwards, the proportion of paraffins gradually increases through the solar oil, till in the heavy oil the olefines vanish entirely.

Separation of Paraffins from Olefines in a Naphtha Fraction.—100 c.c. of the fraction with b. pt. 145°—150° were treated with pure bromine in dim gaslight. The bromine was added in small quantities until a slight excess was present, the flask being well shaken and kept cool. The product was then distilled under a pressure of 100 mm., with the following result:—From 85° to 90°, 1 c.c.; from 90° to 110°, 57 c.c.; from 110° to 120°, 2 c.c., giving a total of 60 c.c. of paraffins. The residue in the still (olefine bromides) was black and nearly solid, the compounds being almost entirely decomposed. The colour of the distillate was at first pale yellow, it became dark blue on standing, but on shaking with potassium hydroxide the yellow colour returned. After washing with water the oil had a sweet ethereal odour.

When treated with concentrated sulphuric acid, a black tar separated; the process was repeated till the acid ceased to be discoloured. The colourless oil measured 55 c.c. Concentrated nitric acid removed a small quantity of tar, and when no further action took place fuming nitric acid was added, and more tar removed. A mixture of nitric and sulphuric acids produced a considerable amount of black tar with evolution of heat; the treatment

was repeated till no further blackening occurred, and the decomposition products removed by agitating with sulphuric acid. When all discoloration ceased the oil was washed with potassium hydroxide and water, and finally dried with calcium chloride and sodium. The naphthenes and all other compounds except paraffins are completely decomposed by the above treatment.

Thus from 100 c.c. there were removed by bromine 40 c.c., by sulphuric acid 5 c.c., by a mixture of nitric sulphuric acids 8 c.c., leaving as saturated hydrocarbons 47 c.c.

The same fraction, 145°—150°, gave the bromine addition figure 52.2 per cent. When this is calculated to nonene (b. pt. 145° C.), it represents 53.7 c.c. of olefines, and by difference 46.3 c.c. of paraffins, whereas 47 c.c. were actually found.

Since the acid treatment gives pure paraffins only, and

volume measured 231 c.c. Thus from 1000 c.c. of refined naphtha, 250 c.c. were separated with b. pt. above 200° C. 8 c.c. were removed with sodium hydroxide, 432 c.c. were removed with sulphuric acid, 79 c.c. were removed by nitric and sulphuric acid mixture, and 231 c.c. of pure paraffin were left.

The saturated hydrocarbons were distilled from ordinary flask, the residue then remaining in the flask was black and solid on cooling. The sp. gr. of the distillate (20°/15°) was 0.7434. This distillate was then fractionated by four successive distillations. The results are given in the following table, and also the properties of each fraction. The asterisks mark the points of maximum volume, a minimum increments of specific gravity, and refractive index. All these points coincide with the theoretical boiling points and show the concentration of the distillates in the neighbourhood of the normal paraffins.

		174.75	63.94										

the bromine absorption result agrees so closely with it, the above method of calculation was used to obtain the ratios of paraffin to olefine in the whole series of distillates.

The above 47 c.c. of paraffin yielded, after two distillations, with a rod-and-disk column, the following result:—Below 149°, 3 c.c.; 149°—151°, 18 c.c.; 151°—157°, 6 c.c. The paraffin, boiling at 149°—151°, gave a dark brown colour with sulphuric acid, showing that a certain amount of decomposition had taken place during the distillation; it was agitated repeatedly with sulphuric acid till no further blackening was observed, then washed and dried as before. It then stood for two days exposed to a strong light, and, on testing with sulphuric acid, gave a dark coloration, proving that further decomposition had ensued. This was repeated a number of times, and after each time the acid was blackened.

After complete removal of the products of decomposition, and washing and drying over sodium, the oil was kept for two months in the dark, and on again testing with sulphuric acid, no change was observed. The physical properties of the product showed it to be nonane.

Paraffins. Separation of the saturated hydrocarbons in the distillate up to b. pt. 200° C.—1000 c.c. of refinery naphtha were distilled for the lighter portion boiling below 200° C.; the distillate measured 750 c.c. It was then agitated for six hours with a 25 per cent. solution of sodium hydroxide, and after settling, the alkaline tar was removed by means of a separating funnel. The oil left measured 742 c.c.; one litre of concentrated sulphuric acid was added to the residue in six separate quantities, agitated for three hours after each addition, and the acid tars run off after settling; the last acid was only slightly blackened. The volume of oil left was 310 c.c. 200 c.c. of a mixture of equal volumes of nitric and sulphuric acids were agitated with the oil, and kept cold; much tar was removed with the acids, and 269 c.c. of oil remained. The nitro-compounds and decomposition products were dissolved out by sulphuric acid till the latter remained clear; the residual oil was then neutralised with solid sodium hydroxide, washed with water till neutral, allowed to settle for two days and dried over calcium chloride and sodium. The final

The Vapour Densities were determined by Victor Meyer method. Only the first fraction gave a successful result the ordinary apparatus with glass boiling tube. Ethylzozate boiling at 211° C. was used. With the higher boiling fractions, condensation took place at the top of the tube, causing the water in the trough to rush in. To overcome this difficulty a long copper cylinder with brazed bottom was made, and filled with paraffin. In this the Meyer tube was completely immersed up to delivery tube, and the whole apparatus surrounded by galvanised iron cylinder to shield it from draughts. The temperature of the paraffin bath was kept about 30° higher than the boiling point of the fraction. The fraction boiling above 170° could not be determined by this method, and though every possible precaution was taken, the water was drawn back every time, and cracked the tube.

The freezing point method with benzene, as the solvent was employed for the higher fractions. During freezing crystals separate in a very finely divided state only in small quantity, so that the alteration in concentration is very slight. This method gave the most satisfactory results.

Nitro-paraffins.—On treatment with a mixture of nitric and sulphuric acids, 100 c.c. of naphtha yielded 7 c.c. of paraffin, evolving much heat and nitric peroxide fumes. This low yield shows that by rapid oxidation the paraffins are attacked, forming nitro-paraffins which remain dissolved in the acid mixture. The 7 c.c. of oil were deep red in colour and possessed a sweet, pleasant odour, and in addition a peculiar buttery smell. The butyric odour is recognised in all the nitrated oils, and is removed by continuous washing with water or sodium hydroxide solution, although the washings possess it well.

The above product was shaken with a little sulphuric acid to remove most of the red colour; it then gave a deep red nitrolic acid reaction, characteristic of primary nitro-paraffins, and also an intense red colour with sodium hydroxide solution—a property which Worstall has shown to belong to the primary dinitro derivatives of hexane, heptane, and octane. Worstall has succeeded in converting a number of the normal paraffins completely

o nitro and oxidation products. In his experiments likewise noticed the "persistent butyric-like odour," mentioned above, and concludes that it is due to the nitro paraffins themselves, since he has obtained only oxidation products with nitric acid (succinic, oxalic, etc., and carbonic acids). The pure mononitro paraffins possess the sweet ester-like odour.

All the nitro paraffins are insoluble in water, and only slowly dissolved by a saturated solution of sodium hydroxide. They dissolve in concentrated sulphuric acid, being converted into the corresponding fatty acids and other products of decomposition. In order to dissolve the nitro compounds completely, it is therefore very necessary to treat with successive portions of concentrated sulphuric acid till the latter ceases to be discoloured, and then to wash with a saturated solution of sodium hydroxide many days.

SOLAR OIL.

The solar oil obtained from the Hartley refinery, has an aqueous port-wine colour, and leaves a deep crimson stain on paper. $d_{4}^{20}=0.843$; refractive index, 1.4678.

Distillation.—1 litre of the oil was distilled at 100 mm. pressure through a four-bulb "pear" fractionating column, and a Liebig condenser, into a vacuum receiver of about 1 c.c. capacity. Each fraction could be drawn off from the receiver without destroying the vacuum or interrupting the distillation.

The freshly distilled fractions possessed a pale greenish-yellow colour. Nos. 1, 2, and 3 had a most pungent odour and quickly became opaque, while Nos. 4, 5, and 6 were colourless and remained clear.

After standing for a few days (in the dark) all the fractions had become dark red in colour, and a bright crimson deposit was observed in each. The first three fractions possessed no fluorescence, while the last three showed a pink blue fluorescence.

No. 1	deep red, opaque	no fluorescence.
2	deep red, nearly opaque	faint blue fluorescence.
3	deep red, clearer	dark blue fluorescence.
4	deep red, quite clear	light blue fluorescence.
5	light red, very clear	pale greenish-blue fluorescence.
6	dark brown, clear	light green fluorescence.
7	dark brown, clear	light green fluorescence.

All the distillates possessed a faint not unpleasant odour at first. On standing, Nos. 1 to 4 changed in appearance. A thick sediment, having an intense crimson colour, was noticed in the oil and round the stoppers, and a pink, unpleasant odour was developed.

Nos. 5, 6, and 7 remain unaltered, and possess very little odour.

The portion of the heavy oil boiling above 280° C. (760 mm.), and contained in fractions 5, 6, and 7, is quite different in properties from the rest. It has a light green fluorescence, remains transparent, and is almost odourless. The last column in the table shows it to consist almost entirely of paraffins, solidifying at the ordinary temperature.

An attempt was made to extract the solid paraffins by freezing the heavy oil at 15° C., and then subjecting it to pressure in linen cloth. The press was completely immersed in ice and salt for some hours and the pressure gradually increased.

The solid paraffin obtained from 600 c.c. of heavy oil was 38 grms.=6.3 per cent. of the heavy oil. This is much below the true amount present, and is due to insufficient pressure.

One hundred c.c. of the heavy oil were treated with successive small portions of sulphuric acid until black tar ceased to separate. Sixty-five c.c. of saturated hydrocarbons were left. On shaking the residual oil with hot water, a thick creamy emulsion formed, which would not separate. Further addition of concentrated sulphuric

HEAVY OIL.

The heavy oil from the Hartley refinery has a dark reddish-brown colour, and leaves a deep crimson stain on paper. $d_{4}^{20}=0.8945$; refractive index, 1.4974; setting point, 0° C.

One litre was distilled under 100 mm. pressure, and fractionated twice with a "pear" still-head. The following results were obtained:—

Boiling points.		Volume Per cent.	Setting point.	Sp. gr.	Refractive index.	Br absorption.	
At 100 mm.	At 760 mm.					Substitution.	Addition.
1 110°—150°	below 190°	0.9	—	0.8597	1.4795	21.4	20.0

7 275°—300°	310°—320°	9.0	+ 22	0.9248	1.5179	19.75	0.3

The colour of the distillates was pale brown when collected; but after standing some weeks in tightly-corked bottles in the dark, the following changes were observed:—

acid failed to give a clear oil, and even after 20 successive trials, the acid was discoloured and decomposed.

AROMATIC COMPOUNDS.

Benzenes.—A quantity of the refinery naphtha was distilled, and the following fractions separated:—65° to 100° for benzene, and 100° to 150° for toluene and xylene. These fractions were treated with successive small

portions of concentrated sulphuric acid, and the unsaturated hydrocarbons removed as tar. The remaining oil was then nitrated in the ordinary way with acid mixture, and on pouring into water a yellow oil settled on the

bottom. This was separated and washed. After reduction the following tests were applied:—

Sodium hypochlorite gave a brownish-purple colour. Erythrophenate reaction—brown changing to bluish-green. Potassium chlorate and sulphuric acid added to the nitro-compound gave deep purple. Benzene and its homologues with b. pt. up to 150° C. are, therefore, present in small quantities.

Phenols.—The tar obtained by the treatment of the naphtha with 25 per cent. sodium hydroxide contains phenols and acidic compounds. On neutralising with sulphuric acid it gave a very strong odour of phenol and coal tar creosote. After settling, the surface film was removed and the following tests applied:—

Ammonia and sodium hypochlorite gave a blue and hydrochloric acid a red colour; ammonia and bromine vapour gave a deep blue; Millon's reagent gave deep crimson; and Liebmann's reaction a brown, green, then crimson colour on diluting, becoming blue with potash.

The Red Colouring Matter in the Distillates.—The most intensely coloured of the fractions was chosen for the purpose of ascertaining the behaviour of the crimson colouring matter with solvents. A heavy oil distillate, No. 3, b. pt. 225°–235°, was first treated with 25 per cent. solution of sodium hydroxide to remove the phenols. Alkalis change the colour to brown, but do not dissolve or remove it. After washing with water, sulphuric acid was added in excess and the black tar settled and removed. The residual oil on shaking with water formed a white emulsion which would not separate. The acid tar contained the colouring matter; on shaking with water, the aqueous solution was deep crimson, and the thick tar had a purple-black colour, and strong aromatic odour. A part of the colouring matter is, therefore, soluble in water. The aqueous solution gave all the reactions of pyrrol:—(1) Fine shaving, moistened with hydrochloric acid, gave an intense crimson colour with the above aqueous solution, also with the clear yellow naphtha, the solar oil, the heavy oil, and the aqueous extract from crude oil. (2) The aqueous extract from the crude oil when filtered is quite clear; after standing some time a brown deposit settles on the bottom (pyrrol). (3) Clear distillates heated with dilute hydrochloric acid give a ppt. of pyrrol-red. (4) Isatin in sulphuric acid with any of the oils mentioned above gives a deep ultramarine blue.

The Acid Tars.—The several acid tars and sulphuric acid residues were distilled separately by superheated steam. The colourless sulphuric acid became bright crimson on boiling, then changed to dark purple, the colour disappearing suddenly after about half an hour. From about 3 litres of tar 40 c.c. of a pale yellow oil distilled over. The distillate possessed a very fragrant ethereal odour, after the sulphur dioxide was absorbed. The clear yellow distillates were treated with sulphuric acid; no change took place in the cold at first, but they became slightly darker on standing, and when warmed gradually became red, and finally blackened. The pale yellow distillates probably consist chiefly of the unsaturated hydrocarbons which had been combined as sulphonic acids in the tar, and also the higher homologues of benzene as well as small quantities of paraffins from imperfect separation of the tar. On diluting the residue from the above sulphuric acid tests, a strong odour of onions was evolved, and in one portion of the washings from the original tar a distinct peppermint odour was observed.

The yellow distillates tested for thiophen gave no reaction with isatin, but the original tar from the crude oil gave the faint green and purple colour of indophenin, showing the presence of traces of thiophen.

SUMMARY AND CONCLUSIONS.

The results of this investigation show that—

The *Crude oil* is a mixture chiefly of paraffins and olefines. The olefines form 70 per cent. of the lightest distillate, b. pt. 30° C., and as the b. pt. rises they gradually decrease, till at 280° they disappear; the rest of the oil distilling between 280° and 400° consists almost entirely of paraffins.

The *Naphtha*, which forms 9 per cent. of the crude, consists of approximately equal parts of paraffins and olefines, with b. pt. from 30° to 200°, and sp. gr. from 0.660 to 0.800. The paraffins present amount to 30.50 per cent., and from pentane up to undecane; the corresponding olefines are shown by the bromine addition compounds formed.

The *Solar oil* extends from b. pt. 200° to 270°, and sp. gr. from 0.800 to 0.870. It contains 50 per cent. paraffins in the lightest portion, and they gradually increase with rise of b. pt. and sp. gr. to 80 per cent. 270° b. pt. The paraffins included between these limits are dodecane to pentadecane.

The *Heavy oil* begins to boil at about 270° C., and the distillate shows the commencement of crystallisation of solid paraffin on cooling; the sp. gr. increases from 0.870 upwards. The lightest portion boiling between 270° and 300° contains the last traces of the olefines, w. pentane and hexa-decane. From b. pt. 300° upwards, paraffins $C_{17}H_{36}$ to $C_{30}H_{62}$ make up the entire bulk of the heavy oil. This portion is solid at ordinary temperatures, and possesses a bright emerald-green fluorescence.

At the end of the distillation the last of the heavy is followed quite suddenly by the appearance of *chryseol*. In the portion of the oil boiling below 150°, benzene and its homologues were detected in minute quantities. A notable amount of *phenols* is also present, and a minute trace of *thiophen*. Nearly all the crude distillates contain pyrrol red, which is partly deposited on standing.

Naphthenes.—When the distillates are treated with concentrated sulphuric acid till no further action takes place and all the tar has been removed, sulphuric acid and nitric acid mixture removes a further quantity as tar, some cases nearly half of the remaining oil. Sulphuric acid alone has no action on naphthenes; the acid mixture produces nitro derivatives which dissolve in the tar. The specific gravity of the naphtha distillates is considerably higher than that required for the corresponding paraffins and olefines. The naphthenes are characterised by their high specific gravities.

These points show the probability of naphthenes being present in the oil.

Table showing the principal hydrocarbons present, and the approximate amount of each:—

United States.—1s. each to the Secretary of the Society.
French.—1 fr. 25 c. each, to Belin et Cie, 56, Rue des Francs-Bourgeois, Paris (3^e).

—PLANT, APPARATUS & MACHINERY.

Copper Pipes; Action of Brine on—. H. Keil. *Woch. f. Brau.* 1905, 22, 495.

ASE is cited in which the copper refrigerating pipes employed in connection with a brine-circulating system were corroded away in a few months. Examination of the brine taken from the system showed the presence of 1 per cent. of ammonia, which had presumably entered the brine through a leakage in the coils of the ammonia ice-making machine employed. It was found that the presence of such small quantities of ammonia in the brine, or even the presence of ammonia vapours in the air to which pure brine was exposed, was sufficient to exert a considerable action on pieces of copper immersed in the liquid. It is known that, even when free from ammonia, brine containing small quantities of iron salts slowly corrode copper piping. Such corrosion, it is stated, can be prevented by making the brine alkaline with sodium carbonate.—J. F. B.

Oil in Water from Condensing Engines; Determination—. J. McFarlane and J. Mears. *XXIII.*, page 38.

ENGLISH PATENTS.

Sluice with Liquid, Fluid or Gaseous Agents; Apparatus for Treating—. H. H. Lake, London. From H. Messoliers, Ténès, and P. Regnier, Mustapha, Algeria. *Eng. Pat.* 18,512, Aug. 26, 1904.

The apparatus consists of a vertical cylindrical vessel 1, provided with perforated "sleeves" 11 for the introduction and withdrawal of liquids, and with a feeding hopper 2. An inclined pipe 3 having a perforated compression-cone 4. An Archimedian screw 5, to which a right-handed or a left-handed motion can be imparted alternately, and a heating or cooling jacket 12, projects at an angle from the bottom of the cylinder 1. The material to be treated passes down the cylinder 1 and up the inclined pipe 3, is discharged from the open end of the compression-cone 4. Liquid treating agents are admitted through the pipes 6 and 7, steam and gaseous or liquid agents through the pipes 11, any liquid from the compression-cone 4 being returned through 14. Volatile products are taken away by the pipe 13, light liquids by the taps 9 and heavy ones by 8. The sludge-valve 29 is used for cleaning out. It is stated that several different treating agents may be used at

the same time in different parts of the apparatus, which occupies little space and gives very complete extraction owing to the constant movement of the particles treated, and to the use of the counter current principle.—W. H. C.

Filter-Press Frames; Impts. in—. P. Menra, Tournai, Belgium. *Eng. Pat.* 24,446, Nov. 11, 1904.

SEE *Fr. Pat.* 340,503 of 1904: this J., 1904, 815.—T.F.B.

Filtering, or Separating Liquids from Solids, or Matters from Impurities and for Analogous Operations; Apparatus for—. C. Dreyfus, A. Meyenberg and The Clayton Aniline Co., Ltd., Manchester. *Eng. Pat.* 11,957, June 7, 1905.

A STRONG closed vessel, made in two parts with only one joint, is divided internally into an upper and lower compartment by a perforated partition, which carries the filtering medium, preferably "porous filter stone." It is stated that by the use of porous stone or tile instead

of filter-cloths, higher temperatures and much greater pressures can be employed. The material to be filtered is placed in the upper compartment of the vessel which is then closed and steam or compressed air is admitted above the material, which may be heated, if desired, by a steam jacket. The liquid portion is forced through the filtering medium into the lower part of the vessel from which it flows away by a pipe near the bottom. Several different methods of supporting the filter grid to facilitate emptying are described.—W. H. C.

Volatile Solvents Diluted in Air; Process and Apparatus for Taking up, Collecting, Aspiring, Drying, Cooling, Fixing and Recuperating; Vapours of —. E. Bouchaud-Pracq, Angoulême, France. Eng. Pat. 6075, March 22, 1905. Under Int. Conv., March 26, 1904.

SEE Fr. Pat. 341,690 of 1904; this J., 1904, 859.—T.F.B.

Drying Apparatus; Impts. in —. A. Forschieppee and C. Schäter, Dortmund, Germany. Eng. Pat. 6762, March 30, 1905.

A HORIZONTAL cylindrical drying chamber is provided with a steam-jacket surrounding the lower half and with an air-jacket surrounding the upper half. The material to be dried is fed in at one end and air enters the upper jacket at the same end, and, after becoming heated during its passage through the jacket, enters the drying cylinder proper at the other end. It then passes back over the material to be dried, and leaves the cylinder saturated with moisture, through the opening by which the substance is introduced. A fan is used for aspirating the air.—W. H. C.

Separators; Impts. in Centrifugal —. N. S. Bök, Stockholm. Eng. Pat. 9115, May 1, 1905. Under Int. Conv. May 9, 1904.

THE claim is for the axially located supporting body shown at 4, 5, 6 in the figures. Fig. 1 is a section of one form of the invention applied to an ordinary Alpha-Laval separator; figure 2 is a cross section of fig. 1, along

FIG. 1.

FIG. 2.

the line AB. The supporting body consists of a central 4, of square section, provided with the extension-pipe 5, terminating in a T-shaped end piece 6, and forming abutments against which the walls 3, forming the passages 2, bear. The liquid to be separated passes down feed-pipes 1 and 4 into the "slime-cup" 7, from which it travels up the passages 2 and passes out between partitions 10 by the openings 15 and 22 formed between side walls 3 and the bearing pieces 6.—W. H. C.

UNITED STATES PATENTS.

Filters; Process of Removing Solid or Semi-solid Material from Containers of Pressure —. C. W. Merrill, L. S. D. U. S. Pat. 798,200, Aug. 29, 1905.

THE sludge is removed from the containers of pressure filters, without separating the units of which they are made up, by introducing a stream of liquid, vapour or gas under pressure, immediately below or behind the sludge and at a point near to the outlet.—W. H. C.

Filter-Press —. H. T. Shriver, New York. U. S. Pat. 798,304, Aug. 29, 1905.

THE filtering-chamber of the filter-plate is connected by a channel to a groove or duct, provided with a separate inlet and formed in the joint surface of the plate which surrounds the filtering-chamber.—W. H. C.

Evaporating Apparatus —. W. E. Jaques, Grand Rapids, Mich. U. S. Pat. 798,681, Sept. 5, 1905.

THE liquid or semi-liquid to be dried is fed into a tank where it is converted into froth by agitators. An endless band travelling on rollers and provided with "wipers" takes the froth from the tank, and delivers it on to an endless band conveyor working in a horizontal chamber, which is fed with hot air. At the end of this chamber a belt delivers the partly dried material into another vertical drying chamber also supplied with hot air.—W. H. C.

FRENCH PATENTS.

Cooling and Evaporating Liquids; Apparatus for —. H. R. Worthington. Fr. Pat. 353,346, April 13, 1905. SEE Eng. Pat. 7468 of 1905; this J., 1905, 792.—T. B.

Volatile Products [Solvents]; Process for the Complete Recovery of —. A. A. P. Mallet. Fr. Pat. 349,971, June 16, 1905.

THE recovery of volatile solvents used in various industries is effected by aspirating the air, which may be mixed in any proportion with the vapour to be recovered, from a vessel A where the solvent is vaporised, by the pump B, provided with the regulating valve *a*, and forcing it through a train of apparatus. The air first passes through the atmospheric cooler C from which any condensed liquid runs off to the store tank M through the trap siphon *b*. It next passes through the water-cooled worm D to the separator E, the condensed liquid flowing through *b* to M whilst the air passes on to the condenser cooler F. This vessel is similar to the well-known distilling column, and is fed through the pipe C with a cooled liquid in which the vapour is not soluble. The air is forced to bubble through successive layers of liquid on bonnet plates *g*, and the cooling liquid and condensed

it flow down from plate to plate through the pipes *b*. The condensed liquid is specifically heavier than the gas agent, the pipes *h* are provided with caps *i* in that the condensed liquid may flow down before cooling liquid. The mixture passes through the absorber *d*, and the air goes on to the absorber *G*, which has similar construction to *F*, but is fed by the pump in the reservoir *I*, with a liquid which will absorb and dissolve the vapours. From *G* the air, now completely freed from vapour, escapes by the pipe *c*, the saturated absorbent flows into the distilling in *J*, heated either by fire or by a steam coil. The air distilled off passes through the condenser *L* and cap *b* to *M*, and the absorbent flows by the pipe *f* through the condenser *K*, to the reservoir *I* to be used again. Owing to the methodical and thorough treatment, very complete recovery of the vaporised acetylene is effected, even when mixed with a very large portion of air, and consequently the working place *A* is kept well ventilated.—W. H. C.

II.—FUEL, GAS, AND LIGHT.

Acetylene; Combustion of — W. A. Bone and G. W. Drew. Chem. Soc. Trans., 1905, 87, 1232—1248.

The authors find that the combustion of acetylene is a case of essentially the same type as that obtaining in the cases of methane, ethane and ethylene (see this J., 1901, 601; also Chem. Soc. Trans., 1902, 81, 536; 1903, 74; 1904, 85, 693, 1637); the oxygen is initially incorporated with the hydrocarbon, giving rise to unstable molecules which rapidly undergoes thermal decomposition into simpler products. When sealed glass vessels are filled with mixtures of acetylene and oxygen at atmospheric pressure and temperature, are heated, action begins at 250° C., or even a somewhat lower temperature, and proceeds rapidly at 300° C. Explosive combustion takes place at 350° C. in the case of mixtures containing 1 or 2 mols. of acetylene to 1 mol. of oxygen, and at about 375° C. with mixtures containing 3 mols. of acetylene to 3 mols. of oxygen. A decrease in initial pressure or an addition of oxygen over and above an equimolecular proportion, causes a rise of the ignition point. The presence of more than an equimolecular proportion of oxygen retards the rate of com-

bustion below the ignition point, and also, as H. B. Dixon has shown (Phil. Trans., 1893, 184, 183), above it. The formation of carbon monoxide and hydrogen, which occurs in accordance with the empirical equation:— $C_2H_2 + O_2 = 2CO + H_2$, when an equimolecular mixture of acetylene and oxygen is exploded, must be ascribed to the secondary decomposition of the unstable hydroxyacetylene first formed. Carbon monoxide and formaldehyde are produced at an early stage in the slow combustion of acetylene, probably as the result of the decomposition of the unstable hydroxy derivative $(HO)C:C(OH)$. The production of formaldehyde certainly precedes that of steam. The slow combustion may be represented by the following scheme:—

Below the ignition point, the formic and carbonic acids, produced at stages 3 and 4 respectively, are decomposed into steam and oxides of carbon, whilst above the ignition point, the formaldehyde produced at stage 2 (or possibly also the dihydroxyacetylene at stage 1) is resolved into carbon monoxide and hydrogen.

In the explosive combustion of acetylene, separation of carbon occurs only when the reacting mixture contains more than an equimolecular proportion of the hydrocarbon, being due to the secondary decomposition of the excess of acetylene. In contact with a hot catalysing surface, such as porous porcelain, acetylene even in presence of oxygen unites with steam, forming acetaldehyde:— $HC:CH + H.OH = CH_2:CH(OH) = CH_3.CHO$. No evidence of the formation of benzene was observed in any of the experiments.—A. S.

Gas; Use of — for Power and Heating. E. A. Dowson. Paper read before the Birmingham Assoc. Mech. Eng., April 27, 1905.

Gas for Illuminating, Heating and Power Purposes; Manufacture of —, and Apparatus therefor. H. S. Elworthy and S. Williamson, London. Eng. Pat. 14,333, June 25, 1904.

COAL gas, after purification in the usual way and after removal of hydrocarbons, other than methane, by scrubbing with paraffin oil or the like, is passed over metallic nickel at a temperature of 250° C., for the purpose of converting the carbon monoxide and hydrogen present into methane and water, according to the equation, $\text{CO} + 3\text{H}_2 = \text{CH}_4 + \text{H}_2\text{O}$. If necessary, hydrogen may be added to the gas before treatment. If carbon dioxide is present as well as carbon monoxide, the gas is treated first at 250° C., as above, and then at 350° C., to convert the dioxide also into methane according to the equation, $\text{CO}_2 + 4\text{H}_2 = \text{CH}_4 + 2\text{H}_2\text{O}$. To the gas after treatment there may be restored the hydrocarbons which were removed by scrubbing. Instead of coal gas alone, a mixture of coal gas with water-gas, Dowson gas, or the like, with or without the addition of hydrogen, may be subjected to the process; and such a mixture may be prepared by passing water-gas or the like through a superheater and then through a column of fresh coal, whereby the hot gas effects the destructive distillation of the coal, the coke left by the latter being used in turn for the production of the water-gas, &c.

—H. B.

Combustible Vapour or Gas [Carburetted Air]; Manufacture of —. A. Shiels, London. Eng. Pat. 18,456, Aug. 25, 1904.

A RECIPROCATING pump, driven by a hot-air engine, draws air through a carburetter, and delivers the carburetted air to a gas-holder. The air is heated by the burner of the hot-air engine, and, as it enters the carburetter, is maintained at a constant temperature, by means of a thermostatic device. The rate of flow of air through the carburetter is kept constant, however the gas production may vary; to effect this, the downward stroke of the pump piston is caused by a cam driven by the engine, whilst the upward stroke (which sucks the air through the carburetter) is given by a spring, which has been compressed during the downward stroke. The time occupied by the suction stroke, therefore, depends only on the strength of the spring, and not on the speed of the pump. The burner of the

engine is fed with gas from the holder, and is controlled by the movements of the latter, so that the speed of the engine is regulated automatically according to the consumption.—H. B.

Gas; Apparatus used in the Manufacture of Coal —. A. A. Johnston, Ilford, Essex. Eng. Pat. 19, Sept. 6, 1904.

TO enable the depth of seal of the dip-pipes in the hydrant main to be varied to any desired extent, whilst gas being made or the retorts are open, the hydraulic main is divided into two longitudinal compartments by means of a plate depending into the liquor. The upper part of the two compartments may be brought into communication by means of a by-pass pipe; or this pipe may be closed, and gaseous pressure applied (say, from a holder) to one of the compartments, so as to cause the liquor to rise to the desired extent in the other compartment, into which the dip-pipes depend. The depth of seal can thus be varied. The compartment enclosing the ends of the dip-pipes communicates with the furnace main; the other has an outlet to a tar chest, the flow being regulated by means of a slide-valve.—H. B.

Gas; Manufacture of Coal — [Vertical Retort]. Wilson, Kirkintilloch. Eng. Pat. 19,774, Sept. 1904.

A VERTICAL gas retort is constructed in two portions, the upper portion being enclosed in a furnace, whilst the lower portion, or "cooling chamber," is open at the bottom and dips into a water seal, which allows coke to be withdrawn without the admission of air or interruption of the distillation in the upper portion. The steam generated by the hot coke, on meeting the water of the seal, is converted into water-gas and passes off along with the coal-gas from the top of the retort. The cooling chamber may be either exposed to the atmosphere, or wholly or partly provided with a water-jacket.—H. B.

Gas Producers; Impts. in —. A. Cerasoli, London. Eng. Pat. 19,827, Sept. 14, 1904.

THE producer, which is intended for use with bituminous fuel, is constructed with blast inlets at the top and bottom of one side, and gas outlets at the top and bottom of the other side, these inlets and outlets being controlled by linked valves in such a manner that the air is directed alternately upwards and downwards from the inlets in an oblique direction through the main mass of fuel, the gas produced during each phase being led off by the diametrically opposite outlets. A hanging wall separates the freshly-charged fuel from the upper gas-outlet.—H. B.

Carburetted Air; Process of —, and Apparatus therefor. J. Gore, Sutton, Surrey. Eng. Pat. 19,414, Sept. 16, 1904.

AIR is forced through a revolving drum partly filled with liquid hydrocarbon, to which a certain quantity of naphthalene may be admixed, into a compressed-air chamber. The air thus partially carburetted is then admitted to the carburetted chamber, where it meets a spray of oil which is pumped through suitable nozzles at the top of the chamber. The carburetted chamber is always kept free from liquid oil, any excess being collected on the bottom and run into the supply tank.—R. L.

Gas Producer Working with a Varying Consumption of Gas; Process for Maintaining the Temperature of —. E. Capitaine, Frankfort-on-the-Maine, Germany. Eng. Pat. 7310, April 6, 1905. Under Int. Conv., April 9, 1904.

SEE Fr. Pat. 353,085 of 1905; this J., 1905, 961.—T. F. B.

Smoke or Products of Combustion; or Gases or Vapours containing Noxious Vapours, Apparatus for Washing or Purifying —. L. P. Barnabé, London. Eng. Pat. 6, Magna, Forli, Italy. Eng. Pat. 11,158, May 6, 1904.

A VERTICAL spindle is mounted to revolve on a step-bearing at the bottom of a cylindrical vessel. The lower part of the spindle and the step-bearing are enclosed in a

ing case, to prevent access of water and dirt, is supplied continuously to the vessel from a supply and is kept at a constant level within the vessel, the water surface, the spindle carries arms projecting downwards into the water, and agitating the same as the spindle is being rotated. The inlet for the products of combustion consists of a horizontal tube passing through the side wall of the apparatus and communicating with a central vertical cylindrical chamber, the end of which is open and is situated just above the rotating arms. The lower part of this inner cylindrical chamber is provided with an exterior annular flange, to which a similar flange is fixed to the inside of the vessel. While the water is being agitated, these flanges act as baffle-plates, preventing the water from rising too high, and at the same time causing the smoke which is drawn through the apparatus by a centrifugal fan, to come in close contact with the water. The impurities washed out from the smoke can be moved through a cock and a man-hole at the bottom of the apparatus.—R. L.

Impts. in Treating —, and *Apparatus therefor*. B. Ransford, Upper Norwood, Surrey. From L. F. Yacono, Buenos Ayres. Eng. Pat. 22,050, Oct. 13, 1904.

Smoke is led into a chamber where the soot deposits, then drawn, by means of a centrifugal pump, through a gauze screen into a coke tower, where it deposits of the solid hydrocarbons. The tower is fitted with a heating coil, through which boiler feed water is passed. Gases then pass into another column packed with oil or other material, over which light petroleum or gas flows. The smoke thus treated is returned to the furnace or stored in a gas-holder.—R. L.

descent Media for Lighting Purposes; Manufacture of —. R. Langhans, Berlin. Eng. Pat. 14,687, July 17, 1905.

Manufacturing mantles according to Eng. Pat. 12,950 (this J., 1900, 649), an improvement is effected in the following proportions of oxides:—Thoria, 256 mols.; ceria, 2.25—4 mols.; zirconia, 1 mol.; 1 mol.; beryllium, oxide 1—1.14 mols.; and cerous oxide, 0.125—0.25 mol.; and by adding mols. of sulphuric acid to the solution of the salts.—H. B.

FRENCH PATENTS.

ettes; Process for the Manufacture of —. E. A. Sh and W. Grant. Fr. Pat. 353,507, April 18, 1905. Claim is for the addition of water to the coal dust, of which the briquettes are formed. Not more

than 10 parts by weight of tar are used to every 20 parts of water, and 100 parts of coal dust, the mixture being then pressed and the water expelled. For the purpose of adding the water is to ensure a thorough mixture of the tar with the coal dust, so that only a small quantity of the former is used. It is stated that such briquettes do not require heating during the manufacture, and that they do not soften whilst burning, provided that not more than 10 parts of tar are used to every 100 parts of coal. For paving, the tar may also be mixed with water and the mixture with the gravel, sand, &c. The mixture is spread on the road, and the water pressed out by a heavy roller.—W. H. C.

Retorts; Furnace with Vertical —. P. de Lachomette, Villiers and Co. Fr. Pat. 353,197, April 10, 1905.

The retort setting consists of four pillars resting on the generator and regenerator. The conduits for gas, air and products of combustion are transversely arranged between these pillars. The retorts are constructed in three parts, luted into each other, to avoid ruptures. The spaces around these parts are divided by partition walls. Inlets for air are provided at various points, and gases, escaping combustion in the generator, are burned in the top compartment of the furnace.—R. L.

Gas Generator capable of Utilising any kind of Fuel. A. de Karischeff. Fr. Pat. 350,915, June 23, 1904.

The generator consists of a chamber in which solid fuel is distilled with production of coke; of a lower compartment in which part of the products of combustion are burned, producing the heat required to dissociate the gases and vapours and raise the temperature of the necessary air; and a third chamber on top of the second one, in which, at a temperature of about 3000° C., combustion of another portion of the distillation products takes place, and where, by means of an injected combustible liquid, the carbon dioxide is reduced to carbon monoxide.—R. L.

Gas Generators; Suction —. H. F. Smith. Fr. Pat. 353,293, March 7, 1905.

See U.S. Pat. 786,063 of 1905; this J., 1905, 540.—T. F. B.

Gas Producers; Process for Regulating the Air Supplied to Suction —. H. F. Smith. Fr. Pat. 353,415, March 7, 1905.

See U.S. Pat. 786,063 of 1905; this J., 1905, 540.—T. F. B.

Gas; Process and Apparatus for the Manufacture of Illuminating — with Continuous Admission of Coal. P. Busse. Addition, dated March 14, 1905, to Fr. Pat. 348,411, Dec. 1, 1904 (this J., 1905, 540).

The rotating cylinders in the feeding hoppers are provided with helical grooves, by means of which the coal is continuously fed into the retorts. The setting for these cylinders has a cooling arrangement to keep down the temperature and thus reduce wear and tear of the movable parts. The gas chambers are combined in a battery by suitable conduits for the hot illuminating gas, which serves to heat two regenerators beneath each gas chamber by means of suitably-constructed flues. The coal is so distributed in the gas chamber that the coarse lumps are accumulated close to the walls, whilst the smaller are heaped together in the centre.—R. L.

Gas-Producer. Leede Process Co. Fr. Pat. 353,502, April 18, 1905.

The producer consists of an iron casing, lined with refractory material, into which coal or coke is charged. At one end of the producer is an oil burner, worked by compressed air, for heating the fuel, and a regulated supply of air is introduced through an annular channel surrounding the burner. A further quantity of air is admitted near the outlet of the chamber and mixed with the gas produced, the mixture being aspirated from the generator by a fan driven by a belt. The speed of the fan is regulated by means of two oppositely-placed cones, one of which is fixed on the pulley driving the belt. By altering the position of the band which connects the cones, the alteration of speed is effected.—W. H. C.

Gas Purifiers Lighting — T. Redman. Fr. Pat. 353,628, April 21, 1905.

SEE Eng. Pat. 9514 of 1904; this J., 1905, 611. — T. F. B.

Wicks of Candles, Lamps, Tapers, &c.; Process for Increasing the Infusibility of — A. Haase. Fr. Pat. 353,339, April 13, 1905. Under Int. Conv., June 14, 1904.

SEE Eng. Pat. 3438 of 1905; this J., 1905, 666. — T. F. B.

GERMAN PATENT.

Gas; Process of Purifying, Illuminating and Coking — by means of Ferric Hydroxide Mud. E. Riepe. Ger. Pat. 159,613, Jan. 1, 1902.

THE gas passes through a suitable scrubber in the same direction as a quantity of ferric hydroxide mud, the desulphurised gas is drawn off to the holder, whilst the mud passes back to the end of the scrubber in which the gas entry pipe is situated. On its passage back it meets with a current of air or oxygen, which reoxidises it, when it may be used for a further operation. — T. F. B.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

Coal-tar and its Properties. J. Gasbelucht., 1905, 48, 826—827.

A table is given, showing the proximate constituents and the quality of over 100 different samples of coal-tar. — W. H. C.

ENGLISH PATENTS.

Distilling and Separating Unequally Volatile Elements contained in a Complex Mixture, particularly in a Mixture of Hydrocarbons, such as Naphtha, Crude Petroleum, different Kinds of Tar or the like. A. Baudry, Kieff, Russia. Eng. Pat. 29,479, Dec. 31, 1904.

THE liquid to be fractionated is introduced through pipe 1 to condenser C, where it cools, and is heated by vapours from column B; it then passes through (which is heated by liquid from boiler M) and pipe 2 column A, where it falls on the plates and is boiled. The vapours coming from M through pipe S. The liquid then passes through pipe 3 into the boiler M, where it is heated directly by the furnace F, and also superheated steam coming through pipe 4, agitated by discs, shown in dotted outline, mounted on a shaft a, rotated by a pulley. The vapour passes through pipe 5 into A, and thence into the fractionating columns B and D; they are then completely condensed in C and C', the condensed liquids descend again into the columns. It is stated that in this process each of the sections of the columns B and D contains distillate of constant composition, and of which the boiling point corresponds to the temperature of the section. It is further stated that petroleum, tar, tar distillates, alcohols, and other similar mixtures can be completely separated into their constituents by this method. The pressure in the apparatus may be lowered by connecting the refrigerator R, by pipe 18, to a barometric condenser. The cocks π_2 , π_3 , &c., lead to diminutive condensers attached to apparatus wherein the boiling of a small portion of the distillate in each of the sections of the columns may be tested from time to time. — T. F. B.

Lubricants; Impts. in — L. A. A. Hennequin. G. J. B. Cayeux, Compiègne, France. Eng. Pat. 11,679, June 3, 1905.

CAMPHOR, dissolved in petroleum, is added to or mixed with animal, vegetable or mineral lubricating oils, so as to furnish a product containing 10 to 250 grms. of camphor per litre; or a solution of 70—125 grms. of camphor in one litre of petroleum may be used. — C. S.

FRENCH PATENTS.

Coal; Process and Apparatus for the Manufacture of Coke, Ammonia, Illuminating Gas, Tar, Benzene, &c., by the Distillation of — J. G. Aarts. Fr. Pat. 353,128, April 7, 1905.

THE material to be distilled and carbonised is introduced continually into the retort, passing first into the heating zone in the centre, and then into zones getting gradually cooler. To obtain a high proportion of gas, a maximum temperature of 1100° C. is required, while for a production of coke and products of distillation, the temperature is kept at 600°—800° C. By the progressive cooling of the coke with the aid of a hydraulic seal, the lower end of the retort, steam and water-gas are formed. Part of the steam heated to 500° C. may be admitted to the upper zone at the same temperature, whilst a portion of the water-gas may serve for the heating of the Carburetting oil can be introduced at suitable points into the retort, which may be of vertical or other form. — L.

Coke; Recovery of Coal Gas in the Manufacture of Sulphuric Acid — P. L. Hulin. Fr. Pat. 350,020, Jan. 25, 1904.

PRODUCER gas from an ordinary producer is used for the heating of coke ovens after being mixed with about 15 to 30 per cent. of coal gas, distilled off in the preparation of coke in an oven. The mixture is burned with hot air, the furnace being provided with a regenerator. — L.

GERMAN PATENT.

Sulphur Derivatives of Mineral Oils; Process for Purifying Sulphonated — G. Hell und Co. Ger. Pat. 161,663, Dec. 23, 1900.

THE impure, red-brown coloured sulphonated derivatives of sulphur compounds of mineral oils (chiefly sulphonic acids) are purified by first removing the organic salts by dialysis, passing steam through the solution, extracting it with ether-alcohol, and again passing steam through the residue. The products thus obtained

stated to be free from the disagreeable odour possessed by similar products which have not been subjected to analysis.—T. F. B.

IV.—COLOURING MATTERS AND DYE STUFFS.

aldehyde-Azo-Benzoic Acids. F. J. Alway and V. D. Bonner. J. Amer. Chem. Soc., 1905, 27, 1107-1120.

One of the authors stated in 1902 (see this J., 1902, 1022) that *p*-oxybenzaldehyde when heated with concentrated sulphuric acid to 110°–120° C. is converted into a brown substance having the characteristic properties of the hydroxyazo compounds. Since then Human and Weil (this J., 1903, 1239) have contended that *m*- and *o*-oxybenzaldehydes when heated with concentrated sulphuric acid are converted into the isomeric benzaldehydeazobenzoic acids. The authors have repeated the experiments of Human and Weil, with the result that their first view is confirmed, *m*-oxybenzaldehyde being converted into the isomeric hydroxyazo compound, whilst *p*-oxybenzaldehyde yields a mixture of hydroxyazo compounds. The *m*- and *p*-benzaldehydeazobenzoic acids were prepared synthetically and it was found that they did not agree in properties with the products obtained by Human and Weil, which were in probability hydroxyazo compounds, as they were capable of staining the skin and dyeing wool and silk, properties not possessed by the benzaldehydeazobenzoic acids.—A. S.

Orange IV.; The Nitro Derivatives of —. P. Juillard. Bull. Soc. Chim., 1905, 33, 974–994.

The nitro derivatives of Orange IV. (phenylaminoazobenzene-*p*-sulphonic acid) are met with in commerce as Indian Yellow, Citronine, Azoflavine, &c. The dyestuffs consist of a mixture of soluble and insoluble nitro compounds. The soluble compounds isolated by the author are three mononitro, two dinitro and one trinitro derivative of Orange IV.; these are present partly as normal salts, partly as acid salts, and it is entirely to these that Indian Yellows, &c., owe their dyeing properties. In all cases the nitro group (or groups) is in an *o*- or *p*-position to the NH group. The insoluble portion of the dyestuffs consists of nitrodiphenylamines, of which there exist three mononitro, two dinitro, two trinitro, and occasionally tetranitro derivative; the nitro groups here also are either ortho or para to the NH group. The author's observations indicate that the positions of the nitro groups do not affect the shade of the dyestuff; the difference in shade between mono- and dinitro derivatives is considerably greater than that between di- and trinitro derivatives.

Mononitro derivatives of Orange IV.—The three derivatives isolated had the nitro groups in the positions 2, 4 and 8 respectively, Orange IV. being represented as

They are present, together with *o*-*p*- and *p*-*p*-dinitrobenzylamine, in the less highly nitrated derivatives of Orange IV., which dye wool and silk golden yellow (Indian Yellow, Curcumeine, &c.). The 4-nitro derivative is the most abundant. They can be distinguished by the reactions of their aqueous solutions with hydrochloric sulphuric acid. The 4-derivative gives a blue-black coloration followed by a precipitate of the same colour; the 2-derivative gives a precipitate soluble in excess, producing a violet-red solution; the 8-derivative undergoes no change in dilute solutions, but in concentrated solution gives a precipitate insoluble in excess of acid. The 4-nitro derivative is prepared by nitrating Orange IV. in acetic acid solution with $\frac{1}{2}$ mols. of nitric acid, the temperature being kept below 25° C.; a mixture of 4-mononitro, and of the dinitro acids, together with nitrodiphenylamines and diazobenzenesulphonic acid

results. The product is filtered, dried, and extracted with toluene, and the mononitro derivative purified by recrystallisation of its potassium salt. The other two mononitro acids are produced on nitrating Orange IV. in acetic acid solution with 1 mol. of 20 per cent. nitric acid; the dinitrodiphenylamines are removed from the product by extraction with toluene and the two acids separated by fractional crystallisation of their potassium salts, that of the 2-nitro derivative being less soluble. The two potassium salts are isomorphous.

Dinitro derivatives of Orange IV. are three in number: One, the 2,4-derivative, is not present in the commercial dyestuffs, but was obtained synthetically by heating bromo- or iodo-dinitrobenzene with aminoazobenzene-*p*-sulphonate of soda in presence of sodium acetate. The 4,8-derivative may be obtained by nitrating either Orange IV. or the 4- or 8-mononitro derivative. It may also be obtained, together with the 2,8-derivative, by nitrating the nitrosamine of Orange IV.; this gives a mixture of the nitrosamines of the two dinitro derivatives, and of 4,10- and 2,10-dinitrodiphenylamines. This product is washed, the diphenylamine derivatives removed by treatment with toluene, the nitroso groups split off the dinitro derivatives by heating with alcohol in presence of sulphuric acid, and the acids separated by recrystallising the mixed potassium salts, of which that of the 4,8-dinitro derivative (which is more abundant) is less soluble.

Trinitro derivatives of Orange IV.—Two trinitro derivatives have been isolated; the 2,4,8-derivative is obtained by direct nitration of Orange IV., or by nitrating either of the dinitro derivatives. The second trinitro derivative, the 2,4,6-compound, was obtained by heating picryl chloride with aminoazobenzene-*p*-sulphonate of soda in presence of sodium acetate. When treated with cold nitric acid this latter trinitro derivative gives a mixture of 2,4,6,10-tetranitrodiphenylamine and a brown substance which has not been examined, but which is thought probably to be a tetranitrated Orange IV.—T. F. B.

ENGLISH PATENTS.

Dyestuffs; Manufacture of New Azo —. H. E. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 24,045, Nov. 7, 1904.

SEE Fr. Pat. 347,655 of 1904; this J., 1905, 329.—T. F. B.

Anthraquinone Derivatives; Manufacture of —. [Anthracene Dyestuffs]. H. E. Newton, London. From the Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 24,869, Nov. 16, 1904.

SULPHONIC acids of *p*-amino- or *p*-alkylamino-hydroxyanthraquinones containing the sulphonic group in the unsubstituted nucleus, are obtained by sulphonation of these substances in the presence of boric acid or by the sulphonation of their boric esters. By the usual methods of sulphonation the sulphonic group is introduced into the nucleus already containing the hydroxyl and amino group. The new substances are stated to be of value both as dyestuffs and as intermediate products.—H. L.

Quinizarin [Anthracene Dyestuffs]; Manufacture of —. H. E. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 1499, Jan. 25, 1905.

SEE Fr. Pat. 350,957 of 1905; this J., 1905, 796.—T. F. B.

Dyestuffs; Manufacture of Azo —. H. E. Newton, London. From the Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 4359, March 2, 1905.

MONOAZO black dyestuffs for wool, stated to be identical with those obtained by the combination of diazotised nitroacyldiphenylenediamine with aminonaphtholdisulphonic acids or their acidyl, alkyl, aryl or glycin derivatives, and subsequent saponification of the intermediate products (Fr. Pat. 347,655; this J., 1905, 329), are produced by replacing the aminonaphthol acids by the corresponding naphthylenediaminedisulphonic acids or their mono-acidyl, alkyl, aryl or glycin derivatives. It was

found that, during the process of saponification, one amino group in the naphthylenediamine nucleus is replaced by a hydroxyl group.—H. L.

Dye-stuffs of the Anthracene Series; Production of Green — Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 353,549, April 19, 1905. Under Int. Conv., Sept. 23, 1904.

SULPHONIC acids containing a sulphonic group in the anthraquinone ring are prepared by treating 1,4-diaryl-diamino-8-hydroxyanthraquinones with a sulphonating agent in the presence of boric acid. A mono- and a disulphonic acid derivative of 1,4-di-*p*-tolyl-diamino-8-hydroxyanthraquinone prepared in this way are described. The former dyes unmordanted or mordanted wool yellowish-green shades and its chrome lake on cotton is very fast to soaping. The disulphonic acid gives bright, yellowish-green shades in dyeing or printing. Both produce brighter, yellower shades and are more suitable for calico printing than the isomeric mono- and disulphonic acids (substituted in the side chain), which are produced by the ordinary method of sulphonation.—H. L.

3,4-Dichloraniline; Process of Making a New Sulphonic Acid of — Act.-Ges. f. Anilinfabr. Fr. Pat. 353,451, March 16, 1905.

ONE hundred and sixty-two parts of 3,4-dichloraniline are heated with 105 parts of sulphuric acid (66° B.), about 215° C., until a sample of the mixture is completely soluble in sodium carbonate solution. The product dissolved in sodium carbonate solution, and the sulphonic acid precipitated by addition of hydrochloric acid. The acid, which is in all probability 3,4-dichloraniline sulphonic acid, is characterised by its sparing solubility in water (1 in 200 at 100° C., 1 in 1000 at 20° C.). It produces, on treatment with sodium nitrite in the usual manner, a diazo derivative which is with difficulty soluble in water, and the salts of this new acid are very easily crystallised.—T. F. B.

Dye-stuffs and Derivatives from Anthracene [Benzothrone Dye-stuffs], and their Application in Dyeing and Printing; Production of a Series of New — Badische Anilin und Soda Fabrik. Third Addition to March 20, 1905, to Fr. Pat. 349,531, Dec. 21, 1904 (this J., 1905, 192, 726, 840, 841). Under Int. Conv. Feb. 15, 1905.

THE anthraquinones, their sulphonic acids and reduction products, mentioned in the main patent may be replaced by substituted derivatives of these compounds, and their homologues, and these may be condensed with an anhydride of glycerol, or with ethers of such anhydride or glycerol, instead of with glycerol itself.—H. L.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILE YARNS, AND FIBRES.

Dye-stuffs on Animal Fibres; Identification of — A. G. Green, H. Yeoman and J. R. Jones. XXI page 1034.

ENGLISH PATENTS.

Silk-like Threads; Manufacture of — O. Imray London. From Farbwerke vorm. Meister, Lucius & Brüning, Höchst a/Main, Germany. Eng. Pat. 21,904, Oct. 12, 1904.

SEE U. S. Pat. 779,175 of 1905; this J., 1905, 129.—T. F. B.

Burner particularly applicable for the Gassing of Textile Yarns and Threads; Improved Atmospheric Gas — C. P. Ehmann, Withington, Lancs. Eng. Pat. 22,604, Oct. 20, 1904.

A METAL plate of slightly greater diameter than the orifice is placed over the top of a Bunsen burner, in order to deflect and increase the width of the flame and to prevent charred pieces of thread from falling into and choking the burner tube. Three different types of brackets for supporting the plate from the top of the burner tube are figured and claimed.—W. H. C.

Textile Piece Goods in Bleaching, Printing, Dyeing and like Operations; Apparatus for Guiding or Guiding and Distending — W. Mycock, Manchester. Eng. Pat. 19,953, Sept. 16, 1904.

INSTEAD of the usual central swivel or pivot, the guiding appliances are mounted in yielding end supports arranged to temporarily yield against an increase of pressure either end, due to the deviation of the cloth from its true course.—H. L.

Electrodes for Electrolysers used in the Manufacture of Bleaching Liquors. R. Kother. Eng. Pat. 70,404, April 3, 1905. XI4., page 1021.

Dye-stuffs; Manufacture of Blue — by *Oxidation of the Fibre.* O. Imray, London. From Farbwerke vorm. Meister, Lucius and Brüning, Höchst a/Main, Germany. Eng. Pat. 406, Jan. 9, 1905.

A VARIETY of blue shades, fast to washing, soap, alkali

acid, is obtained by oxidising on the fibre a mixture of alkylated diaminodiphenylcarbinol and *p*-hydroxy-*p*-aminodiphenylamine. When *p*-hydroxydiphenylamine is used, the leuco base may be prepared separately, subsequently applied to the fibre and oxidised; such leuco base may be prepared by heating 18.5 grms. of oxydiphenylamine with 32.6 grms. of tetraethylaminodiphenylcarbinol, and 10 c.c. of 20 per cent. sulphuric acid to 100° C. for several hours, and then salting the leuco compound, which is dissolved in water, the base liberated by addition of alkali. The substances may be mixed with the requisite solvent, thickening and oxidising agent in the usual way; no free mineral acid is necessary: the oxidation may be brought about by organic salts and chlorates. Instead of using an enylcarbinol derivative, the corresponding diphenylamine derivative may be used; it is probable that in a case the carbinol is formed as an intermediate product. The dyestuff obtained from the leuco base described is particularly fast to soap and sodium carbonate solutions. The shades of the dyestuffs obtained from hydroxydiphenylamine are, in general, purer and more vivid than those from aminodiphenylamine, but require the addition of a little tannin to render them faster to acids.—T. F. B.

Large lot of Dyed Textile Fabrics; Manufacture of Dyes for the —. J. Y. Johnson, London. From discche Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. Eng. Pat. 25,284, Nov. 21, 1904.

Third Addition, of Nov. 23, 1904, to Fr. Pat. 297,370, 1900; this J., 1905, 672.—T. F. B.

UNITED STATES PATENT.

Manufacture of Artificial —. H. Bernstein, Philadelphia, U.S.A., Assignor to Art Fibre Co., New York. U.S. Pat. 254,027, Sept. 5, 1905.

Liquor obtained by boiling raw silk is added to a solution of cellulose in aqueous ammoniacal cupric oxide. The solution is subjected to a gradual increase of temperature, and then formed into filaments, which are treated in an acid bath. The threads may further be treated in a solution of castor-oil, which has been treated with sulphuric acid and sodium hydroxide [sodium sulcinoleate], before or subsequently to the passage through the acid bath.

Two products are claimed—one containing cellulose gum from the liquor obtained by boiling off silk, the other containing cellulose, this gum and a gelatinous substance.—H. L.

FRENCH PATENTS.

Copper Oxide: Process for Recovering —, and for the Preliminary Treatment of Textiles in the Manufacture of Artificial Textile Fibres. R. Linkmeyer. Fr. Pat. 251,187, April 10, 1905.

For the economical manufacture of cellulose threads it is important to recover all the copper dissolved (from the waste cuprammonium) in the alkaline "forming" solutions. To accomplish this, it is proposed to utilise such alkaline solutions for the preliminary treatment of cotton or other vegetable fibres, previous to their conversion into artificial silk. Cellulose thus treated is said to be readily soluble in ammonia, the extra copper required being added to the solution in the form of ammoniacal copper.—T. F. B.

Dyeing Vegetable Textiles by Means of Sodium Peroxide; Process of —. E. Saint-Hilaire and E. de Cassseau. First Addition, dated March 28, 1905, to Fr. Pat. 346,831, Oct. 5, 1904.

Substances necessary for carrying out the process described in the principal patent (see this J., 1905, 2381) are weighed out and kept as two separate mixtures, ready for solving when required. One mixture consists of the sodium peroxide and boric acid, and the other of the caustic soda and alkali silicate, together with an absorbent earth, such as kieselguhr.—T. F. B.

Bleaching; Process of —. E. Brossard. Fr. Pat. 353,113, April 7, 1905.

ALL the operations of bleaching are carried out in a single apparatus, consisting of several units, one of which is shown in the accompanying diagram. The fabric passes over roller 1 and between rollers 2 and 3, and then over roller 6 and down into tank *b*, which contains the necessary liquid; a certain amount of the fabric is allowed to hang slack in the tank so as to permit sufficient treatment. The material leaving the tank again passes over roller 1, and thence between rollers 2 and 3, and 4 and 5, where it is squeezed; it now passes over roller 7 and down into a small receptacle *t*, in which a length is allowed to go slack, in order that, if one of the units has to be stopped for a short time, the whole apparatus need not be stopped.—T. F. B.

Plants; Preparing Dried — for Bleaching and Dyeing. Seibt und Becker. First Addition, dated April 7, 1905, to Fr. Pat. 349,323, Dec. 21, 1904 (this J., 1905, 671).

WHEN the alkaline substances, e.g., alkali carbonates, mentioned in the main patent are soluble with difficulty in alcohol, alcoholic solutions are prepared by adding the requisite amount of alcohol to an aqueous solution of the substance.—H. L.

Warps; Method of and Apparatus for Printing —. G. Morton. Fr. Pat. 353,543, April 19, 1905.

SEE Eng. Pat. 9341 of 1904; this J., 1905, 616.—T. F. B.

VI.—COLOURING WOOD, PAPER, LEATHER, &c.

ENGLISH PATENT.

Dyeing, Cleaning, Washing and the like [Feathers]; Apparatus for —. J. J. Grossard, London. Eng. Pat. 18,194, Aug. 22, 1904.

THE machine is composed essentially of an outer vessel for the dyeing or cleansing liquor, inside which is mounted one or more perforated, corrugated casings capable of being revolved. In operating, the goods (principally feathers) are placed within the latter which are then rotated. A strong current of liquor is thus sent through the casings, and the goods are at the same time (it is claimed) subjected to a very effective rubbing.—H. L.

FRENCH PATENTS.

Paper with Designs; Process and Means for Producing Coloured Tones or Darker Shades or Shades as Dark as Desired on the Ground Colour of Coloured —. R. Schmiedel. Fr. Pat. 333,564, April 20, 1905.

A QUICKLY-DRYING liquid is applied to the face side of the paper with coloured ground. The liquid is made up of a solution of gum arabic, casein, glue, dextrin, or other binding agent soluble in water, to which are added (1) soap to facilitate combination with the ground; (2) saponified oil, to permit of printing while the surface is moist; (3) glycerin, to obtain a pure shade; and (4) denatured alcohol as a sicative, together with a transparent colour when the finished article is to resemble a printed aquarelle.—H. L.

Leather; Process of Dyeing —. Act. Ges. f. Anilinfabr. Fr. Pat. 353,350, April 13, 1905.

Nitric Acid; Process of Manufacturing —. H. H. Niedentühr, Halensee, Germany. Eng. Pat. 4353, March 2, 1905.

SEE Ger. Pat. 155,995 of 1903; this J., 1905, 497.—T. F. B.

Salt Pans; Apparatus for Drawing —, or for similar purposes. J. Rigby, Winsford, Chester. Eng. Pat. 20,108, Sept. 17, 1904.

time it reaches the upper part. The operating parts, provided with flexible or rigid couplings having a slip play, "whereby the reciprocation is effected with a tensional pull first on one coupling and then on another instead of a push, and buckling is avoided." The drawings, Figs. 1 and 2, show the salt pan with its draw apparatus in side elevation and in cross-section. Longitudinal and transverse bars, A and B, are mounted on the pan D by the grooved wheels C, running on rail (Fig. 2), supported on each side of the pan. The bar B, the frame carry at intervals the scrapers G, suspended chains H from brackets J, so that when the scrapers carried in one direction, they lie with their backs against the brackets, whilst the chains H permit them to yield to inequalities; on the return stroke, they swing clear until on dropping, they are again supported by brackets in a scraping position. Centrally over the pan the stationary cylinder K is mounted with its piston, rods L, working through opposite ends, in connection with pipes from the valve-box M, whereby brine, for instance, can be admitted alternately to opposite ends in order to work the scrapers. The drainage platform S may be adjustably mounted, and the hinged extension T, provided with one or more scrapers, may be caused to ride up the platform.—E. S.

Chlorine; Generation and Application [as Disinfectant] —. J. Hargreaves, Farnworth-in-Widnes, Lancs. Eng. Pat. 20,835, Sept. 28, 1904.

SOLID acid sulphates, such as aluminium sulphate, sodium or potassium bisulphate, formed for transport into blocks of suitable size, are mixed with a suitable portion of bleaching powder, in a receptacle, with addition of water. In the case of an open receptacle, it is placed near to the manhole of a sewer, for instance, and a cover is placed over it, also covering the sewer opening, so that the chlorine evolved may enter the drain. Or a closed receptacle may be used, having a pipe passing from its top, leading to any place or building which it is desired to disinfect.—E. S.

UNITED STATES PATENTS.

Ore-Roasting Kiln. J. McNab, Catonsville, Md. U.S. Pat. 798,524, Aug. 29, 1905.

THE fireplaces are arranged in series, side by side, extending in two rows in which the opposite fireplaces are

FIG. 1.

In drawing salt pans, an inclined platform is arranged to receive the material, which is caused to ascend by the action of a train of scrapers moving on suitable supports to and fro. The scrapers act only during their forward movement, and are caused to swing up clear of the material in the return movement. The inclined platform is of such length that the material, if wet, may be drained by the

back to back. The main gas-flues extend above the fireplaces of each row, and receive the gas from openings in the key blocks to the arched slabs which carry the crown arch to the furnace, and discharge at one end to a nitre oven. A fines-burning flue extends longitudinally above one of the main gas flues, and having forward end connected to a return or dust flue, with

ter extends at the back, and discharges at its rear end into one of the main flues.—E. S.

Carbonic Acid; Apparatus for Producing ——. G. Valzel, Assignor to E. Zusi, both of Newark, N.J. U.S. Pat. 798,239, Aug. 29, 1905.

The apparatus consists of a double shaft reduction space combined with one or two regenerators; means of communication between the regenerators and the space and between the regenerators and a hot-blast device, both fitted with devices for shutting off at will either or both regenerators from the furnace or from the hot-blast device; means for conducting producer-gas from this hot-blast device and into the regenerators; a condenser and main receiver; means for drawing the carbonic acid into the main receiver, means between the receiver and hot-blast device for conducting a portion of the carbonic acid to the hot-blast device to be heated therein, means for conducting the heated gas to the regenerators; and steam-pipes leading into the hot-blast device and extending therefrom, these steam-pipes being connected with the pipes through which the carbonic acid passes from the hot-blast device to the regenerators.—A. G. L.

FRENCH PATENTS.

Electrolysis of Alkali Chlorides; Apparatus for the ——. M. Granier. Fr. Pat. 353,304, March 18, 1905. Id., page 1021.

Nitrites; [Electrolytic Reduction of Lead Oxide to Metal for Use in the] Manufacture of ——. P. J. Petit. Fr. Pat. 353,467, April 14, 1905.

The invention relates to the utilisation of the lead oxide entering in the process of preparing nitrites by acting on nitrates with lead. The lead oxide is made into a paste with an alkaline solution, as, for instance, sodium or potassium carbonate, serving as electrolyte. The mass is spread, to a depth of several centimetres, on a metal base acting as the cathode in a closed vessel communicating with a source of electricity; the anode is constituted of sheet iron, corrugated and perforated, the oxygen gas collecting on which is conducted to a suitable reservoir. The lead thus electrolytically reduced from the oxide is available for reacting on nitrates for the production of nitrites, or otherwise.—E. S.

Sulphide and Alkali or Alkaline-Earth Hydroxides; Process for the Simultaneous Manufacture of ——. W. de Stucklé. Fr. Pat. 353,480, April 17, 1905.

"Sulphate" [Sulphide] and Alkali or Alkaline-Earth Hydroxides; Apparatus for the Manufacture of ——. H. W. de Stucklé. Fr. Pat. 353,496, April 18, 1905. Under Int. Conv., May 21, 1904.

INSULATED zinc is heated with solution of an alkali hydroxide, the evolution of hydrogen being, in some cases, facilitated by addition of iron filings. When the zinc is dissolved, an alkali sulphide is added, but only as much as may be necessary to precipitate the zinc as sulphide. A hydroxide and sulphide of an alkaline earth may be substituted, though not advantageously, for the hydroxide and sulphide of an alkaline base respectively. The zinc sulphide obtained is stated to be in a very finely-divided state. The apparatus in which the process is conducted includes a closed vat having a double bottom for heating by steam, containing receptacles for zinc divided into rows of sieves attached to a central shaft by the revolution of which the charge is agitated. The sieves are divided into a great number of radiating compartments, so that the reacting liquid may percolate through the heaped masses of zinc from compartment to compartment.

Provision is made for conducting the hydrogen evolved to a special measuring device, operating to discharge into the tank quantities of alkali sulphide solution proportioned to the zinc dissolved.—E. S.

Oxygen: Process of Obtaining ——. from Alkali Peroxides. H. Feersterling and H. Philipp. Fr. Pat. 353,282, Feb. 15, 1905.

SEE U.S. Pat. 788,256, April 25, 1905; this J., 1905, 546.—E. S.

Nitrogen and Oxygen: Process for the Production of Compounds of ——. by Electric Means. Soc. West-deutsche Thomas Phosphat-Werke GmbH. Fr. Pat. 353,548, April 19, 1905.

THE gases, during the time that they are submitted to the action of electricity, are under a pressure less than the pressure of the atmosphere. The oxides of nitrogen formed are afterwards brought into contact with solutions of certain salts, of which "sodium chloride" is given as an example, the acids liberated being absorbed by suitable energetic absorbing agents, so that the low pressure is maintained or augmented. In order to convert the lower oxides of nitrogen into compounds richer in oxygen, air is admitted and made to traverse the apparatus.—B. N.

GERMAN PATENTS.

Tower for the Continuous Mechanical and Chemical Purification of Furnace Gases. [Manufacture of Sulphurous Acid]. Metallurgische Ges. A.-G. Ger. Pat. 161,017, Aug. 12, 1902.

THE tower is intended specially for the removal of finely-divided iron oxide and also sulphuric anhydride from the gases from pyrites kilns. It is divided into two parts by a chamber or receptacle in which the washing water, introduced at the top of the tower, collects. This receptacle is at such a distance from the foot of the tower that the ascending gas, at this point, no longer contains any appreciable quantity of sulphuric anhydride. A covered overflow pipe is provided in the centre of the receptacle through which a portion of the washing water passes to the lower part of the tower, in descending which it absorbs any sulphuric anhydride contained in the gas, and at the same time becomes heated, so that any dissolved sulphurous acid is expelled. The water which collects in the receptacle is withdrawn by a pump and introduced again at the top of the tower through a rose; this portion of the washing water, which is circulated through the upper part of the tower, exerts a cooling action on the ascending gas, and purifies it from mechanical impurities.—A. S.

Magnesium Carbonate Trihydrate and Potassium Magnesium Carbonate; Process for the Manufacture of ——. in the Production of Potassium Carbonate by the Magnesia Process. Deutsche Solvay-Werke, A.-G. Ger. Pat. 159,870, March 1, 1903.

IN the preparation of magnesium carbonate trihydrate from magnesia or magnesium hydroxide, and of potassium-magnesium carbonate from magnesium carbonate and a potassium salt by treatment with carbon dioxide under pressure, in the magnesia process for the manufacture of potassium carbonate (compare this J., 1903, 949), claim is made for the application of a pressure of at least 3 atmospheres when gases containing 20 per cent. of carbon dioxide are used, and of a proportionally higher minimum pressure when gases poorer in carbon dioxide are employed. It is stated that under these conditions, the formation of basic magnesium carbonate, or of a carbonate containing less than 3 mols. of water, is prevented. (See also Ger. Pat. 157,354 of 1903; this J., 1905, 442.)—A. S.

VIII.—GLASS, POTTERY, AND ENAMELS.

Glass, Iridescent Stains on —, H. E. Ashley. Trans. Amer. Ceramic Soc., 1905, 7, 159—184.

IRIDESCENCE is considered to be produced by the reflection of light from both the upper and lower surfaces of a very thin transparent layer of varying thickness. The production of iridescent effects requires two processes, first the staining of the glass by the introduction into it of metal, in an oxidising atmosphere, and subsequent colouring of the metal in a reducing atmosphere in which at a sufficiently high temperature a large number of chemical substances will affect stained glass so as to change the colour reflected to any of the prismatic colours, or to blacken the stain. All the experiments were made on an Austrian hard crystal glass, which was first stained with silver, and then subjected to further treatment. With most of the chemicals used, the acid radical seemed to have the greater effect on the colour, except in the case of the metal copper, which was extremely active.

Good results were obtained with powders of silver (or copper) sulphide, ochre, and lampblack in the proportions 1:27:2, and 1:97:2. Small proportions of sodium sulphate gave some of the most brilliant results obtained. Tests with lead sulphide and tin sulphide were about parallel to the copper sulphide tests. The use of metallic magnesium appeared to have no advantage, nor the substitution of an atmosphere of ammonium chloride for a carbonaceous reducing atmosphere. A good bronze colour was obtained from copper acetate, sodium thio-sulphate and ochre in the proportions of 3:1:396. The tests with nitrates were less satisfactory than with sulphur compounds. The formation of adherent oxides of tin makes stannous chloride almost valueless, but aluminium chloride gives similar colour effects without this disadvantage. Some rich effects were obtained with aluminium chloride and metallic copper.

If the ochre used in the pastes is raw, its shrinkage on firing causes the surface of the glass to crackle into small faces, but it has little effect on the surface if previously heated to as high a temperature as the glass is to reach. When the glass is overheated and sinks slightly, its surface takes on a silky gloss, due to fine horizontal striae, composed of very narrow ridges very close together. The original smooth surface will be preserved, however, if there are patches of ochre, lampblack or plaster of Paris. The article concludes with a list of references to the literature of the subject.—W. C. H.

Ceramic Bodies: Note on the Action of "Grog" in —, S. Geijssbeck. Trans. Amer. Ceramic Soc., 1905, 7, 133—143.

The definition adopted by the author is:—Grog is burnt clay or its burnt products in single or compound bodies, in the ground state, coarse or fine, according to the use to which the material is put. It may be refractory or non-refractory, depending upon the class of ware to be produced. The functions of grog in ceramic bodies are:—1. To counteract shrinkage in the green state. 2. To decrease plasticity. 3. To increase the drying qualities. 4. To insure safe burning. 5. To counteract shrinkage in the burnt state. Experiments were made with the object of determining the effects produced (1) by the size of the grog used, and (2) by the amount used. To classify different samples of grog as to size of grain, the samples were screened with sieves of different meshes, for instance, the portion that passed through four meshes to the inch, and was retained by a sieve of eight meshes was designated 4 M. The fine material was the portion that passed through 60 meshes to the inch. The general results obtained were that the size of the grain of the grog has no effect on the shrinkage or porosity, provided the amount used is the same. An increased percentage of grog does not give rise to a proportional decrease in shrinkage nor a proportional increase in porosity. The

first 10 per cent. addition of grog to a clay mixture reduces the shrinkage and increases the porosity far more than any subsequent increase in the percentage of grog. The clay used in these experiments was a fairly plastic potter's clay, burning to a light yellow, and the grog was made broken terra-cotta, burned at a higher temperature than the trial pieces, to eliminate all shrinkage from the grog.

—W. C. H.

Bone China Bodies. A. S. Watts. Trans. Amer. Ceramic Soc., 1905, 7, 204—228.

As the result of a large number of experiments, the author finds that as the amount of flint or uncombined silica increases, the ability of bone ash to act as a flux increases. Tests with a series of trial pieces showed that as the silica increased, so did the fusibility, whilst the translucency apparently decreased. At cone 13, the first member of the series, with no free flint gave a perfect bone china, whereas another member with 5.5 per cent. of free flint warped badly, yet both gave good bone chinas at cone 8. The author concludes from his experiments, that bone china for a range of from cone 8 to cone 12, can be made from mixtures within the following limits:—

0.2 to 0.4 K₂O or higher { 1. Al₂O₃ { 2.8—4.000 SiO₂
1.8 to 2.8 CaO { 0.6—0.933 P₂O₅

—W. C. H.

[Pottery] Bodies high in Silica: Some Evidences that — Craze by Over-fire. C. Weelans. Trans. Amer. Ceramic Soc., 1905, 7, 56—63.

EXPERIMENTS were made upon trial pieces of varying composition, of commercial materials, and burnt "under every-day conditions." The trial pieces were made from a plaster mould, 6½ in. long, one half being round and the other having sharp edges.

The following table gives the composition of the pieces and the results obtained.

Series 0 was fired in the biscuit kiln between cones 14 and 15, being covered with flint in a sagger. The glaze burn was carried on at cone 10.

Series I. When fired at cone 10, all the specimens shivered; the "peeling" was greater as the amount of silica increased. When fired at cone 14, numbers 2, and 4 crazed, whilst the others shivered.

Series II. In this series, Cornish stone was substituted for felspar; each specimen "peeled" worse than the corresponding member of series I., at cone 10; at cone numbers 1 and 2 were good.

Series III. When fired at cone 10 and also at cone 14, all the specimens were good, except No. 1, at both temperatures.

Series IV. All the specimens were good at both cone 10 and cone 14. As the clay content increased, the tendency of the body to crack increased.

Series V. Fired at cones 10 and 14, No. 1 shivered at both temperatures; all the others were good, except No. 5, which crazed at the higher temperature. Glaze formula:—

0.117 ZnO {
0.313 K₂O { 0.43 Al₂O₃ } 2.98 SiO₂
0.570 CaO {

Felspar = K₂O.Al₂O₃.6SiO₂—combining weight = 557.

Cornwall stone = K₂O.2.5Al₂O₃.20SiO₂—combining weight = 1550.

Kaolin = Al₂O₃.2SiO₂.2H₂O—combining weight = 258.

Flint = SiO₂—combining weight = 60.

the author's conclusions are:—

1st: Where the felspar is as high as 20 per cent. of total mixture, no "peeling" will ensue, regardless the quantity of quartz used, providing it does not exceed 50 per cent. of the total mixture, if fired at cone 10.

2nd: That it is safe to use as high as 40 per cent. felspar, the silica not being lower than 20 per cent., out fear of crazing, if the mixture be fired at cone 10.

—W. C. H.

[Pottery] Bodies high in Silica. Discussion on "Some evidences that they Craze by Over-fire". H. E. Ashley. Trans. Amer. Ceramic Soc., 1905, 7, 69—78.

This paper contains a discussion of Weelan's results (see preceding abstract) which the author has expressed by means of triaxial diagrams, that is to say, an equilateral triangle in which each side represents zero per cent. of the three constituents, clays, flint and felspar, each opposite apex denotes 100 per cent. of the constituent. If any point in the diagram is taken, its distance from each of the three sides gives the percentage of each constituent, the sum of which is always 100.

One of the trials fired at cone 10 crazed. All trials less than 15 per cent. of felspar shivered, but with a higher percentage were good. The worst shivering corresponded with the highest amounts of flint and low amounts of clay. While shivering occurred with 40 to 62 per cent. flint, good glazes were obtained on bodies with from 10 to 55 per cent. Both good and shivered glazes were obtained on bodies with 30 to 50 per cent. of clay. When fired with 10 or more per cent. of felspar in the body, over-fired to cone 14, the glaze crazed.

Any glazes have a limited temperature range in which they are good, smooth and bright; so that apart from the

danger of crazing, other causes would make over-firing undesirable as a cure for shivering.

Diagrams of Hecht's results are also given, and reference is made to Purdy's paper (see following abstract), and to Seger's results.

The combined results of these four investigations show:—

1. That crazing is most likely to occur with bodies with a small amount of flint, a large amount of clay, and with from 20 to 30 per cent. of felspar; and an increase or decrease of this latter constituent tends to decrease the liability.
2. That shivering, when it occurs, takes place with a low percentage of felspar, and is further promoted by a high content of flint, and a low content of clay.
3. That harder burning of the body may increase or decrease the tendency to shiver.
4. That changing from a white ware to a porcelain-like structure, will produce crazing, whether the change be effected by a higher glaze fire (Weelans) or by increasing the ratio of kaolin to plastic clay (Purdy).—W. C. H.

[Pottery] Biscuit Body Composition: Limits of Variation in —. R. C. Purdy. Trans. Amer. Ceramic Soc., 1905, 7, 79—88.

This is an account of experiments carried out in reference to Seger's laws as to the correction of crazing and shivering in a glaze by variations—generally supposed to be within narrow limits—of the body composition.

Four series of biscuit bodies were prepared from ball clay, china clay, flint and felspar. In the first, the china clay was increased while the other constituents were kept constant, and no crazing occurred after four years. In the second, the felspar was gradually increased from zero, and in three pieces no crazing occurred after four years, while the other

six crazed at the time of drawing the kiln. In the third series, the flint was increased by degrees, and four pieces did not craze after four years, one of which contained the highest content of flint, one crazed sometime during that period, and two others crazed when drawn from the kiln. In the fourth series, the relative amounts of ball clay and china clay were varied, though the total clay, flint and felspar contents were kept constant. Of these pieces, four stood for four years, one crazed sometime during the period, and one when drawn from the kiln.

The composition of the glaze used was:—

0.49 PbO	{	0.571 B ₂ O ₃
0.12 K ₂ O		
0.15 Na ₂ O		0.19 Al ₂ O ₃
0.24 CaO		2.25 SiO ₂

Seger considered that (1) crazing increases in proportion to the increase of the content of clay substance, (2) in tests of equal clay content, those which contain say Zettlite kaolin craze worse than those which contain more plastic clay, (3) crazing increases with increase of felspar, and (4) it decreases with increase of flint.

The author considers that:—

Seger's laws are not to be construed as operating within these limits under definite conditions.

Owing to the many varying factors in commercial work, the bodies should be so compounded, according to Seger's laws, as to lie safely between the critical points of crazing and shivering.—W. C. H.

Glazes at High Temperatures: Matt — C. F. Binns. Trans. Amer. Ceramic Soc., 1905, 7, 115—121.

A MATT glaze is defined as one that is either white or coloured, and covers the ware in thick mucous masses, which is not brilliant, "but which presents to the touch a quality and texture at once sympathetic and firm." Matt glazes have usually been produced at cone 04 to cone 4 or 5, and the author here considers the advantages to be gained by a high-fired glaze. "The ideal pottery is complete as far as density, strength and vitrification are concerned without any glaze," hence high-fired ware is better than low. The high-fired glazes, too, have a better texture than low-fired ones, and the hues obtainable in a high fire are also better, besides the advantage of utilising reducing actions in a high fire. Two matt glazes, said to be used at Sèvres on gres, came to the author's notice, and one had an oxygen ratio of 2.5 and the other of 2.4, whereas in recent practice at cone 03 it had ranged from 1.2 to 1.4, and at cone 6 had not exceeded 1.6. The glazes were tried at cone 9, and the results led to trying two new ones:—

No. 1.	0.3 K ₂ O	{	0.8 Al ₂ O ₃	2.8 SiO ₂
	0.7 CaO			
	Oxygen ratio, 1.64.			

And No. 2.	0.3 K ₂ O	{	0.7 Al ₂ O ₃	2.6 SiO ₂
	0.7 CaO			
	Oxygen ratio, 1.67.			

The silica content is that due to felspar and kaolin without the addition of any flint. The burn was at cone 9, cone 8 going down inside the saggers. Glaze No. 1 proved too hard, but No. 2 gave a satisfactory matt glaze, with good texture and colours. Taking No. 1 as an upper extreme, experiments were made to determine whether No. 2 was the most satisfactory mixture, the lower extreme being

No. 25.	0.3 K ₂ O	{	0.4 Al ₂ O ₃	2.6 SiO ₂
	0.7 CaO			
	Oxygen ratio, 1.8.			

Two other series were tried, in one of which the oxygen ratio was kept constant at 2.0, and in the other the alumina content was maintained constant at 0.55. The best results were obtained with the following, an intermediate between No. 1 and No. 25, namely:—

0.3 K ₂ O	{	0.64 Al ₂ O ₃	2.48 SiO ₂
0.7 CaO			
Oxygen ratio, 1.69.			

In the other two series it was evident that in one the oxygen ratio was too high, and in the other the alumina too low.

For colour, a number of metallic oxides were tried including copper, which, unexpectedly, did not volatilise. Titanium in the form of rutile appears to be only suspended in the glaze, and has the effect of stimulating crystallisation, and so helps the matt surface, which is, however, scarcely as soft as one founded on alumina.

—W. C. H.

ENGLISH PATENT.

Density or Specific Gravity of Liquid ^{and}/_{or} *Semi-Liquid* Material [Slip, Glaze, Potters' Liquid, &c.]; Apparatus for use in Ascertaining the — J. M. James. Eng. Pat. 18,305, Aug. 24, 1904. NN111., page 1033.

UNITED STATES PATENTS.

Glass; Method of Shaping — F. L. O. Wadsworth, Allegheny, Pa. U.S. Pat. 798,642, Sept. 5, 1905.

GLASS articles are formed by compressing the material between surfaces, simultaneously creating a vacuum between the compressing surface and the glass, and maintaining the vacuum until the glass has set.—A. G. L.

Glass Sheets; Manufacture of — F. L. O. Wadsworth, Allegheny, Pa. U.S. Pat. 798,643, Sept. 5, 1905.

SHEETS are rolled from plastic glass, pressure being simultaneously applied to the rolled portions by surface extending between the rolling device and the glass, the surfaces being practically stationary relatively to the glass and maintaining the pressure during the setting of the glass. Prism-sheets may be made in this way.—A. G. L.

Glass; Manufacture of Sheets of — F. L. O. Wadsworth, Allegheny, Pa. U.S. Pat. 798,644, Sept. 5, 1905.

FIGURED glass sheets, varying in thickness in different parts of the same sheet, are made by first forming or separate table a rough sheet of glass of appropriate varying thickness, and then further forming this sheet a table having a figured surface, without spreading the material laterally.—A. G. L.

Glass; Manufacture of Sheets of — F. L. O. Wadsworth, Allegheny, Pa. U.S. Pat. 798,645, Sept. 5, 1905.

GLASS sheets are made by spreading the glass on a supporting surface, and, before the completion of the spreading operation, pressing successive portions of the sheet against the supporting surface and figuring it on the sheet not in contact with the supporting surface; the pressure maintained during the setting of the glass.—A. G. L.

FRENCH PATENTS.

Glass; Process and Apparatus for Making Sheet — P. T. Sievert. Fr. Pat. 353,344, April 13, 1905. Un. Int. Conv., April 12, 1905.

SEE Eng. Pat. 9211 of 1905; this J., 1905, 926.—T. F.

Enamelling; Process of — without Baking. C. Champigneulle. Fr. Pat. 353,373, April 14, 1905.

THE process consists in the use of a vitreous paste which is applied hot to the surface to be enamelled, and hard on cooling. The paste is prepared by treating a solution of an alkali silicate with calcium sulphate, and decant the thick solution from the precipitate produced. The treatment with calcium sulphate is stated to prevent ulterior formation of salts capable of efflorescing in finished enamel.—A. S.

GERMAN PATENT.

Pottery of all kinds; Process for the Manufacture of — [Utilisation of Waste Product from Thermite Process] C. F. Boehringer und Söhne. Ger. Pat. 160,789, J. 22, 1901.

CLAIM is made for the use of alumina which has been formed artificially, in the manufacture of pottery of all kinds, with the exception of grindstones. The alumina is mixed with a clayey binding agent, then formed into the desired shape.

burned. The fused alumina which it is proposed to use in this way, is obtained in considerable quantities as a waste product of the "thermite" process (this J., 1, 253, 1214). It resembles natural corundum in composition, but is superior to the latter as a raw material in the manufacture of pottery, as it is perfectly anhydrous, does not contain chemically combined metallic impurities. Articles manufactured from this waste product are stated to exhibit less shrinkage and to be stronger than those prepared from natural corundum.

A. S.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

For Tile Bodies made from Clay: General Consideration — R. C. Purdy. Trans. Amer. Ceramic Soc., 1903, 7, 95—114.

The author adopted the following classification of clay tile bodies:—

e Tile	{ vitreous { white. } { coloured. }	{ Prepared facing body on a common clay backing.
e Tile	{ porous . . . clay colours. }	{ Solid bodies formed into geometric shapes.
e Tiles	{ vitreous { white. } { coloured . }	{ Solid bodies formed into geometric shapes.
e Tiles	{ porous . . . clay colours. }	{ Solid bodies formed into geometric shapes.

Face Tiles.—Face tiles consist of a prepared facing body backed with a more common body. In the case of plain tiles the face of the die is covered to the required thickness with the facing body, and the backing then added and pressed. For inlaid tiles a "cell frame" is used, the cells being filled with facing bodies of required colour. In these experiments, the author used a backing of re-clay, ground in a dry pan to a 16-mesh powder.

For vitreous facing mixtures, it was found necessary to add to the two bodies to have a certain quantity of all clay. In all cases tried the use of felspar as a flux in the facing mixture was unsuccessful, but Cornwall stone always proved satisfactory, and, incidentally, the author points out that the silica is apparently present in a peculiar form in Cornwall stone, which prevents the use of this material being taken, as is usually supposed to be possible, by a mixture of felspar, kaolin and flint. Samples of granite from New England quarries behaved as fluxes, just like Cornwall stone. All other fluxes tried were unsuccessful; talc and mineral wool diminished the shrinkage, but made the adhesion of the facing very difficult. The necessity for flint in the facing depends on its relative physical properties of the facing and backing bodies; it is best to add it in the form of a sandy clay. The best formula for a vitreous facing mixture under the conditions of these experiments at cone 7 was:—Cornwall stone, 60; ball clay, 25; and sandy clay, 15 per cent. As porous facing bodies buff and red burning clays are used, the body on burning become dense without losing their natural colour.

Tesserae.—Tesserae are generally made from one body pure. Vitreous tesserae are porcelains compounded to give the requisite toughness, texture and brilliancy of colour. For this a mixture of ball and china clay fired with felspar, fired at cone 10 to 12 has been found satisfactory. The addition of flint makes the body more stable in the fire, less dry in the biscuit, and of a bluish-tint colour and more translucent, and lime is said to strengthen the body. Among fluxes tried, granite chips were used in the same manner as Cornish stone, and the contained ferruginous minerals, according to the fineness of grinding produced the effect of a speckle to a solid colour; the iron content limits the amount of granite that can be used as a flux. Porphyry and basalt are not suitable on this account.

Fluxes were found to be of use as fluxes only in the form of mineral wool. In vitreous facings 5 per cent. mineral wool counteracted the tendency of the "tile dish" but was of no value in vitreous tesserae. Talc and hydromica-schist were useless as fluxes, though the former gave a good cream tint to the body. Zinc oxide imparts a sheen or gloss to the tile; it also fluxed fireclays

to a blue stone very readily, and converted dark buff, salmon, and light reds into shades of red brown.

Other fluxes such as cryolite, fluor spar, &c., were not found to be of any value.

The remarks as to colours, apply both to plain tiles and tesserae. The colours may be either vitreous, namely, imparted to vitreous bodies, or naturally coloured clay and not vitrified. The best vitreous colours are obtained with china clay rather than ball clay. It was found desirable to replace pure vitreous white by a light cream or blue tint, and the most uniform results were obtained by the use of an iron-bearing calcine, composed of alumina, or alumina and zinc oxide and ferric oxide, the latter being obtained by precipitation as hydroxide from ferric chloride solutions by sodium carbonate solution. Oxide of iron in a vitreous china clay body on vitrification causes bluestoning, but iron in silicate minerals such as granite schists, &c., does not, but imparts a cream colour. Iron intimately mixed with flint or alumina and calcined at cone 8 behaves similarly. Vitrification of the body is in all cases necessary to produce full colour effect. Iron precipitated as hydroxide gave better colours than those obtained by merely grinding the oxide of iron with alumina. A good cream was obtained with a stain of 95 per cent. of alumina and 5 per cent. of oxide of iron (precipitated) and increase in intensity of colour is only obtained by increasing the amount of iron in the stain and not by increasing the amount of stain used.

Encaustic Tesserae have buff and red clays as a base, and addition of fluxes to promote vitrification and darken the colour was useless. Buffs, salmon-reds, &c., are due to the clay bodies used. Chocolate is produced with a bright red clay by the addition of 0.5 per cent. of finely powdered precipitated manganese dioxide, whilst with 1.5 per cent. a beautiful jet black is obtained.—W.C.H.

Clays: Plasticity of — F. F. Grout. J. Amer. Chem. Soc., 1905, 27, 1037—1049.

The author deals with the causes of the plasticity of clays and the influence of various conditions and additions. The experiments were conducted in connection with the laboratory work of the West Virginia (U.S.A.) Geological Survey. Plasticity is defined as the property developed in a clay by water, by virtue of which it can be moulded, without crumbling, into forms which remain stiff and unchanged after the removal of the moulding force. It is thus a double property, involving strength, and amount of deformation possible before crumbling. The author points out that the methods of measuring plasticity hitherto suggested have invariably neglected the second of these properties. In the present experiments determinations were made of the compression strength and of the amount of possible flow. The strength was measured by the weight (in 100 grm. units) required to force a Vicat needle of 7 sq. cm. section to a depth of 3 cm. into a mass of clay 4 cm. deep in half a minute. The amount of possible flow was determined by the increase in area of the head of a test rod of clay when it was compressed to the point of fracture. The product of these two values was regarded as the measure of plasticity of the clay, at the stage of wetness in question. As the clay dried, each factor varied, and the product or measure of plasticity rose to a well-defined maximum for a definite percentage of water; this maximum value varied from 1 to 30 for lean and plastic material respectively. After discussing the experimental results obtained, the author concludes that the chief cause of the high degree of plasticity found in clays is molecular attraction depending on the chemical constitution of molecules. When clay is kneaded with water, each grain becomes eventually covered on all sides by a film of water. The cohesion of the water, the adhesion of the grains of clay and the water, and the cohesion of the clay through the films of water, unite to make the moist clay hang together. The films of water also act as lubricants, and the combined cohesion and lubrication is regarded as forming the ultimate basis of plasticity. According to this view plasticity will depend on two factors: First, the distance the clay particles can move on each other without losing coherence; and, second, the amount of coherence, or the resistance to movement. With respect to the first factor, the distance

will vary with (a) the shape and size of the grains, and with (b) the distance through the film that they will attract each other. The second factor, or resistance to deformation, will depend on (c) the friction in the film of water, and (d) the friction of the grains on each other, as they become irregular and penetrate the film. The addition of sand to clay injures the plasticity little at first, because the grains are suspended in a plastic mass, but when the grains of sand are abundant enough to come in contact with their neighbours, the effect becomes considerable, both strength and amount of possible flow being injured. Certain organic colloids increase the plasticity by rendering the water viscous. Plasticity tends to increase as the material is more finely powdered. The presence of plane surfaces (thin plates) increases the amount of possible flow. Molecular attraction has a twofold effect in increasing plasticity. As the attraction becomes greater, the coherence and strength of the mass increase, and the amount of possible deformation before crumbling also increases. Greater fineness of division causes an increase in this action, in that a larger surface is exposed and more water is required, the lubrication being thus improved. The presence of various substances, both colloids and crystalloids, in solution may also increase the attraction.—A. S.

Concrete; Notes on —. C. E. P. Sankey.
Engineering, 1905, 89, 269–270.

The specification for concrete is generally given in the form: x parts of aggregate to 1 part of cement, and further that sufficient sand must be added to fill the voids. This does not take into account the variation in percentage of voids, with material of different sizes. The procedure suggested is:—

1. Settle upon the aggregate to be employed both as to nature and gauge.

2. Measure the amount of contained sand in the aggregate, and this having been removed, determine the proportion of voids; also note the quantity of water absorbed.

3. Choose the quality of concrete for the work.

4. Calculate the amounts of cement, sand and water required, say, for 1 cb. yard, allowing for the sand in the aggregate and the water absorbed.

5. Use measures to hold these amounts, allowing 10 to 20 per cent. overplus in the case of water. To determine the voids, &c., in an aggregate, take a tank containing, say, n buckets of water, each = Q . Let x = the number of buckets of water required to fill up the tank, which contains dry aggregate with contained sand. Allow water to be absorbed thoroughly by the aggregate. Draw off the water, and let x = the number of buckets of water required to again fill the tank. Let y and z be the corresponding quantities required with aggregate free from contained sand. Then voids in $n.Q$ cubic feet of dry aggregate = $z.Q$ cubic feet, or $100 \frac{z}{n}$ per cent. of voids.

Water absorbed by $n.Q$ cubic feet of dry aggregate free from sand = $(y-z).Q$; and $100 \frac{(y-z)}{n}$ = percentage of water absorbed.

The sand contained in $n.Q$ cb. ft. of dry aggregate is $(z-z).Q$ cb. ft., and $100 \frac{z-x}{n}$ = percentage of contained sand.—W. C. H.

Lime; Process of Hydrating —. J. Thomlinson, Portland, Oreg. U.S. Pat. 798,755, Sept. 5, 1905.

LIME is added to a hot mixture of sand, sugar, water and petroleum, and the mixture is thoroughly incorporated, dried, and screened.—E. S.

Fire-Brick. R. O. Hayt, Corning, N.Y. U.S. Pat. 798,788, Sept. 5, 1905.

THIS invention relates to a process of forming a refractory article by mixing finely-divided siloxicon (see Eng. P. 3629 of 1903; this J., 1903, 743), with a liquid silicate sodium so as to form a pasty substance. The latter moulded, and the block subjected to a high temperature so as to burn out the sodium from the compound.—B.

Cement-Clinker; Manufacture of —. C. Ellis, Assignor to Eldred Process Co., both of New York, N.Y. U.S. Pat. 798,175, Aug. 29, 1905.

THE cement mixture is heated in a progressively advancing stream by the combustion of an oppositely moving stream of fuel. The air required for combustion is heated continuously by the waste heat of the products of combustion a portion of which, together with a determined quantity of air, is passed through a deep bed of ignited gas-produce coal. The producer gas obtained is mixed with the preheated air in proximity to the cement mixture at igniting temperature. (See following abstract.)—A. G.

Gas [from Cement Kilns]; Process of Generating —. C. Ellis, Assignor to Eldred Process Co., both of New York, N.Y. U.S. Pat. 798,176, Aug. 29, 1905.

THE gaseous products of combustion and calcination from a cement kiln, which are richer in carbon dioxide and poorer in nitrogen than ordinary products of combustion are withdrawn from the kiln, freed from dust by deposit or filtration, and mixed with a determined quantity of air or oxygen. The mixed gases are then passed through a deep bed of ignited non-flaming fuel and the combustible gas formed is collected.—A. G. L.

Water-Extracting Device [for Cement "Slurry"]. J. Hendrickson, Cleveland, Ohio. U.S. Pat. 798,781, Sept. 5, 1905.

THIS invention comprises a machine for extracting water from "slurry" previous to the latter being burnt. The slurry is measured in predetermined quantities by means of a valved charging chamber. A series of water extractors, movable in relation to the charging chamber is used, and each extractor is successively charged. The extractors comprise press chambers arranged in an annular manner, and moving in a circular path. Plungers operate in the presses, an annular incline being arranged so to depress the plungers as the extractors are moved their circular path, and means are provided for raising the plungers after each depression. Compressed air delivered to the under surface of each plunger through an air passage in the plunger when the pressing operation is completed, but during the pressing process the supply is cut off. Each chamber has a hinged bottle with means for automatically opening and closing the same.—B. N.

GERMAN PATENTS.

Kilns for Burning or Roasting Lime, Cement, Ores & the like; Method of Working —. A. Vandaele, Ger. Pat. 159,767, March 19, 1904.

THE kiln is provided with a movable chimney which can be displaced at will in both a vertical and a horizontal direction, so that the intensity of the fire at any particular part of the kiln can be adjusted.—A. S.

Slag and Quicklime; Process for the Manufacture of a Hydraulic Binding Agent from Granulated Blast-Furnace —. E. Renfert. Ger. Pat. 159,865, A. 15, 1904. Addition to Ger. Pat. 150,769, Jan. 8, 1904.

ACCORDING to the main patent a mixture of granulated blast-furnace slag and quicklime was treated with steam under pressure, and ground, but it was frequently found necessary to dry the mixture before grinding. According to the present patent, the slag alone is treated with steam under pressure, and is then mixed with the quicklime, whereby a dry mixture is obtained, which can be ground directly to an impalpable powder.—A. S.

X.—METALLURGY.

Alloys; Copper-Aluminium ——. L. Guillet. *Compt. Rend.*, 1905, 141, 464—467.

Micrographic and fusing-point examinations of the series of these alloys have led to the recognition of the following constituents:—*a*. A solid solution containing 8 per cent. aluminium, forming large polyhedra, formerly confused with the compound Cu_3Al ; it is contained in all alloys with less than 8 per cent. of aluminium. *b*. Either Al or a solid solution of this composition; it appears in increasing quantity (surrounded by *a*) as the content of aluminium rises beyond 8 per cent. *c*. A solid solution formed in alloys containing 8.6—11.8 per cent. of aluminium by sudden cooling to a temperature just above the transformation point, but not formed when the alloys cool slowly. *d*. A solid solution containing 30 per cent. of aluminium. *e*. Probably the compound Al_2Cu ; crystallites contained in alloys with 46 per cent. of aluminium. *f*. Also the compound Cu_3Al ; it is accompanied by a eutectic in the alloys containing 47—66 per cent. of aluminium. As the aluminium content increases, so does the amount of eutectic, till, at 66 per cent., the whole alloy is eutectic. *g*. Accompanies the preceding eutectic in alloys with more than 66 per cent. of aluminium. It is either metallic aluminium or a solid solution containing very little copper.

The melting-point results agree well with those of Chatelier. All alloys up to 8 per cent. of aluminium solidify at 1035°C .; and alloys containing approximately the following percentages of aluminium solidify simultaneously throughout their whole mass—66, 48, 30, 11—12.

Alloys containing under 8 or over 25 per cent. of aluminium have only one transformation-point; those with 5 per cent. have at least one. The transformation seems to occur in several stages, whatever the order of heatings; that on cooling is sharper. The point is at 490°C ., decreasing as the alloy contains more aluminium till it reaches 390°C . The second point, if doubtful, is about 150°C . (See also this J., 1904, and 1905, 279.)—J. T. D.

With Tellurides. K. Mönkemeyer. *Z. anorg. Chem.*, 1905, 46, 415—422.

First of a series of researches to elucidate the constitution of bismuth-telluride. Bismuth and tellurium were melted together in various proportions, and the solidifying-point determined. This shows two eutectic points, one at 110°C . corresponding to nearly 99 atoms per cent. of tellurium, the other at 388°C ., corresponding to 9 atoms per cent. of bismuth; between these two points is one at 573°C ., corresponding to 40 atoms per cent. of bismuth, or Bi_2Te_3 . Calculation of the point of disappearance of either eutectic, from the observed duration of the period of eutectic crystallisation, also gives the composition of Bi_2Te_3 as that of the only alloy which crystallises completely without alteration of composition; all other alloys solidify as mixtures of the first eutectic ($\text{Bi} + \text{Bi}_2\text{Te}_3$) or bismuth or Bi_2Te_3 , or of the second eutectic ($\text{Te} + \text{Te}_2\text{Bi}_3$) with Bi_2Te_3 or tellurium. The compound Bi_2Te_3 is then the only compound of bismuth and tellurium which exists. The conclusions drawn from these melting-point determinations are entirely confirmed by the microscopic examination of the alloys.—J. T. D.

ENGLISH PATENTS.

Smelting; Manufacture of —, and the Smelting or Reduction of Iron or other Ores or Metals. E. T. Zohrab, London. Eng. Pat. 22,688, Oct. 21, 1904.

Peat is derived from the charring of peat in closed ovens, scrubbed, purified by passage over scrap iron, and condensed, for supply, together with air, to tuyères, of which sets enter an upright smelting furnace. The upper set of the tuyères operates on the ore charged into

the furnace; the second set supplies the tuyères at about the melting zone; and the lowest set supplies them to slightly above the hearth. The tuyères are of special construction, for delivery of conjoint blast of the peat gas and of air. Hydrogen gas, obtained by the electrolysis of water, may be supplied to the furnace with the peat gas, or independently thereof. (Reference is made to Eng. Pat. 26,191 of 1896, and 11,085 of 1900; this J., 1897, 1006, and 1901, 587.)—E. S.

Zinc Blende; Process for Separating by Flotation from Ores, Tailings and Concentrates, and for Preparing such Ores to enable such Separation to be effected. A. J. F. de Bavay, Kew, Victoria, Australia. Eng. Pat. 18,660, Aug. 29, 1904.

The ore or tailing, concentrate, &c., containing zinc blende associated with carbonates is first treated with a suitable reagent to effect the separation of the latter. A suitable method is to treat the wet ore pulp in a closed vessel with carbon dioxide under pressure, and then to wash with water. The ore is then mixed with water to a thin pasty consistence and delivered on to an inclined surface at the foot of which is a well of water or other suitable liquid. The particles of zinc blende float over the surface of the water to a receptacle, and are thus separated from the other constituents of the ore, which sink in the water in the well. The latter part of the process may be carried out in the apparatus described in Eng. Pat. 25,858, of 1904.

—A. S.

Tin; Obtaining and Utilising —, from Tin Slags. C. A. L. W. Witter, Hamburg-Hohenfelde, Germany. Eng. Pat. 24,445, Nov. 11, 1904.

Tin slag or tin waste is smelted with lead to obtain a tin-lead alloy, sulphur being added in amount proportional to the iron present, in order that the latter may be removed as a fusible slag. The tin-lead alloy obtained is subjected to a partial oxidation to obtain a mixture of oxides with a dominant proportion of tin, which oxides may be reduced by known means to obtain an alloy rich in tin.—E. S.

UNITED STATES PATENTS.

Iron Sponge; Furnace for the Manufacture of —. G. Gröndal, Djursholm, Sweden. U.S. Pat. 799,001, Sept. 5, 1905.

Alloy. A. E. Hobson, Meriden, Conn. U.S. Pat. 798,181, Aug. 29, 1905.

THE alloy consists of about 99 per cent. of tin, the remainder being "hardening" material, such as copper and antimony with a small proportion of manganese.—E. S.

Ores, Slimes, and other Materials; Apparatus for Treating Crushed —. A. Z. Clark, Melbourne, Australia. U.S. Pat. 798,568, Aug. 29, 1905.

A GIRDER extending across and supported on the upper portion of a vat or tank, has connected to it, a cylinder depending vertically in the vat. A propeller having a shaft projecting upwards through the centre of the girder, is located in the lower portion of the cylinder, deflecting plates extending from the periphery of the tank to a point slightly beyond the centre of the cylinder, between attached to the opposite side edges of the girder between the tank and the cylinder.—E. S.

Slime Concentrating Table. A. Tetrault and E. C. Pohle, Denver, Colo. U.S. Pat. 798,842, Sept. 5, 1905.

A PAIR of beams are loosely fitted in a pair of bracket guides rising from the corners of a foundation frame. The concentrating table is supported on rocking arms, mounted upon the upper side of each beam, and adapted to swing at right angles to the length of the beams. Means are provided for oscillating the table.—E. S.

Ore Concentrating Table; Dry —. A. Tetrault and E. C. Pohle, Boulder, Colo. U.S. Pat. 798,843, Sept. 5, 1905.

A TABLE with a smooth surface has a cover of transparent

material supported at some distance above it, forming a chamber, openings being left across three edges of the table, whilst the fourth edge is closed. Powdered ore is fed into the chamber through a hopper, which delivers at the closed edge of the table, and the concentrate is discharged through the openings at the opposite edge of the table. A casing acting as an exhaust chamber extends across the openings at one of the edges of the table adjacent to the closed edge, and is provided with a suction device at the end next to the closed edge. A "reciprocating bumping movement" is imparted to the table, which is mounted in a slightly inclined position, and currents of air are drawn in through the openings at one of the edges of the table, and pass diagonally across the moving body of ore to ports, at the opposite edge of the table, communicating with the exhaust chamber.—A. S.

Furnace: Ore-Roasting ——. F. H. Trego, Potosi, Wis. U.S. Pat. 798,844, Sept. 3, 1905.

A CIRCULAR furnace, bounded by an annular wall, has a central fixed pillar, rising from the foundation, and supporting a domed top or cover. The inner periphery of the hearth lies within an annular groove in the pillar, about which it rotates. A radially disposed hollow bar is mounted at the inner end of the pillar, carrying dependent from it a series of hollow ploughs, means for circulating water in which are provided.—E. S.

FRENCH PATENTS.

Copper: Separation of ——. particularly from Low Grade Ores. P. Weiller and A. Weiller. Fr. Pat. 353,029, April 5, 1905.

THE naturally oxidised or calcined ores are mixed with metallic iron and melted, preferably in a blast-furnace, whereby the copper, which at first passes into the slag, is continually withdrawn therefrom.—J. H. C.

Furnaces [for Distillation of Zinc]: Gas ——. with Multiple Burners arranged in Stages and with Central Circulation. L. G. Fromont. Fr. Pat. 353,462, April 8, 1905. Under Int. Conv., April 11, 1904.

THE claim is for special modes of arranging the burners and crucibles and directing the gas or flame currents, particularly in reversing or continuous furnaces for the distillation of zinc, with a view to economise fuel and labour.—J. H. C.

Brazing Metals: Process of and Product for ——. National Brazing Compound Co. Fr. Pat. 353,485, April 17, 1905. Under Int. Conv., April 18, 1904.

Cupola Furnaces for Reduction, Fusion, Calcination, &c.; Preservation of ——. by Interior Linings. F. C. W. Timm. Fr. Pat. 353,566, April 20, 1905.

UPRIGHT cylindrical furnaces, built of refractory material, and adapted for continuous working, are, under the present invention, provided with an interior lining of courses of bricks, which descend with the charge as the latter subsides, provision being made for its renewal at the periphery of the top, from which also the charge is fed in, while the gases of combustion escape through a pipe in the hood or cover, having a funnel-shaped enlargement below. Means for withdrawing the charge by portions, as may be required, by lowering at a slow rate the platform on which it rests, interposing supports for the upper part of the charge during the removal of the lowered portion from a chamber in the base of the furnace, and again lifting the supporting platform, are provided and described in detail. The material for the furnace lining may, in some cases, be the same as that of the charge. The lining is to be increased in thickness when air, enriched in oxygen, is supplied through the tuyères, the position and action of which are described. The lining may, under specified conditions, be of a material which absorbs heat in undergoing chemical change, such as calcium carbonate, in order to increase the durability of the furnace walls.—E. S.

Lead: Process for the Enrichment of Auriferous Argentiferous ——. H. L. Herrenschildt. Fr. 350,012, June 23, 1904.

MOLTEN lead in excess, at a temperature between 400 and 550°C., is poured into molten sodium nitrate at same temperature, and the mixture is agitated so that the sodium nitrate is reduced to sodium nitrite and lead is oxidised. All the gold and silver present will be found concentrated in the excess of lead. The sodium nitrite may be washed out of the oxide of lead and electrolysed for subsequent use.—J. H. C.

Gold: Extraction of ——. from Minerals rich in Antimony. H. R. Herrenschildt. Fr. Pat. 350,013, June 23, 1904.

THE auriferous minerals are melted with metallic antimony, antimony sulphide and carbon, or any other substance capable of producing metallic antimony, in such proportions that the metallic antimony finally produced shall be about one-tenth as much as that contained in the original mixture. The auriferous antimony thus produced is fused directly with sodium or calcium bisulphide with sulphur sufficient to convert nine-tenths of antimony present into sulphide. The resulting alloy of gold and antimony may be finally treated with nitric acid or by any other known method for the separation of gold.—J. H. C.

GERMAN PATENTS.

Iron: Process for the Continuous Production of Refined Iron ——. and Furnace, with several Tap-holes, the Invention of O. Thiel. Ger. Pat. 161,191, Feb. 11, 1902.

MOLTEN pig-iron, together with a suitable quantity of highly-heated ore and lime, is refined in a static hearth-furnace until the whole of the silicon, the greater part of the phosphorus and manganese and a portion of the carbon are removed, if the basic process is followed, or until the whole of the silicon and the greater part of the carbon and manganese are removed in the case of the acid process. The whole of the slag and about one-half of the refined molten metal are then tapped off, and a fresh charge introduced. The refined metal tapped off is conveyed to converters or Martin furnaces for further treatment. It is claimed that by leaving one-half of the refined molten metal in the furnace at each tapping operation, and by using a highly-heated mixture of ore and lime, the temperature of the furnace is maintained at such a point that the working is considerably accelerated. One hearth furnace worked by this method is stated to be capable of refining the whole of the pig iron from a large blast-furnace plant (800 tons or more per 24 hours).—S.

Metals, Metalloids or their Compounds as free from Carbon as possible; Manufacture of ——. E. W. Hoy. Ger. Pat. 161,559, March 23, 1904. Addition to Ger. Pat. 138,808, Nov. 11, 1900.

ACCORDING to the main patent, the impure metal or metalloid was vaporised and forced through a strongly heated layer of its oxide. The use of other suitable oxides instead of the oxide of the metal or metalloid under treatment is claimed in the present patent. In this way, alloy can be obtained of which one of the constituents is non-volatile or not readily volatile at the temperatures attainable in practice. For example, an alloy of iron and titanium, free from carbon, is obtained by heating a mixture of titanium oxide and charcoal, and forcing the vapours produced through a layer of fused titanate acid. The carbon reacts with a portion of the titanate acid to titanium, and this, with the iron to form an alloy free from carbon. A manganese-copper alloy is prepared by heating manganese oxide with charcoal, and forcing the reaction products through a layer of copper oxide.—A. S.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(A.)—ELECTRO-CHEMISTRY.

on Monoxide and Carbon Cells. F. Haber and A. Moser. Z. Elektrochem. 1905, 11, 593--609.

The authors have succeeded in producing a cell in which substances which are active in producing E.M.F. are on monoxide or carbon and oxygen.

This cell warm glass (at about 500° C.) serves as the electrolyte. It is constructed of a soft glass test-tube, inner and outer surfaces at the closed end being nised, and thus serving as electrodes. The current is brought in contact with these platinised surfaces by a brush or coil of fine platinum wire.

Means are also provided for surrounding the inner and outer surfaces of the tube with an atmosphere of the par- gas mixture under investigation. This was ally carbon monoxide diluted with carbon dioxide in one hand, and air on the other.

reful measurements have shown that the E.M.F. at the boiling points of sulphur and phosphorus penta- oxide (about 1.0 volt) correspond very closely with that calculated on thermodynamical grounds, and the same is for the effect of change of concentration of the on monoxide, carbon dioxide or oxygen.

When concentrated carbon monoxide mixtures are used, dissociation of carbon occurs by dissociation of the gas, and cell is transformed into one in which carbon itself forms the active substance.

The present form the cell is only suitable for potential measurements; experiment, however, proves that when a current is taken from it, it is capable of recovering its initial E. shortly after the current is stopped.—R. S. H.

rine and Alkali; Castner Mercury Process for Making —. M. Le Blanc and C. Cantoni. Z. Elektrochem. 1905, 11, 609--612.

A LABORATORY form of the Castner alkali cell suitable for experiments and demonstrations is described. An investigation with this has shown that, if the current density on mercury cathode be at least 0.1 ampere per sq. cm., mercury be kept in slow motion and the concentration of potassium chloride be high, a current yield of over 90 per cent. (at 40° C.) can be attained.—R. S. H.

ENGLISH PATENTS.

anic; [Electrolytic] Method of Separating — from Liquid Food Materials whether used as Liquid or Treated in other Materials to Produce a more or less Solid Food. O. G. C. L. J. Overbeck. Eng. Pat. 24,174. Nov. 8, 1904. XVIII.A., page 1027.

Electrodes for Electrolysers used in the Manufacture of Treaching Liquors. R. Kother, Cunewalde, Saxony. Eng. Pat. 7020, April 3, 1905.

The anode consists of a piece of platinum foil or thin platinum gauze laid upon one side and folded closely at the edges of a plate of insulating material. The cathode consists of a carbon plate pressed closely against opposite side of the insulating plate.—A. S.

UNITED STATES PATENTS.

Electrolytic Process. C. Hering, Philadelphia, Pa. U.S. Pat. 798,790, Sept. 5, 1905.

This invention relates to a process of reclaiming the free acid and depolariser from a mixture of exhausted liquid depolariser and exhausted exciting fluid containing free acid resulting from the operation of a two-liquid primary

battery. The liquid is electrolysed, a porous anode of spongy lead and a cathode of lead peroxide, the anode and cathode combining respectively with the acid and depolariser and forming inert solid compounds on the electrodes. The latter are removed and immersed in a suitable electrolyte with interposition of a porous diaphragm, and a reversed current is passed through the liquid. The electrodes return to their original condition, and the free acid and depolariser are re-formed. The process may also be employed for the removal of an objectionable ingredient from an electrolytic solution containing other substances capable of being electrolysed, such as the removal of an excess of free acid from a solution of a metallic salt, for instance, zinc sulphate, which is being electrolysed for recovery of the zinc at the cathode. —B. N.

Oxalic Acid and its Derivatives; Method of Reducing — by Electrolysis. E. von Portheim. U.S. Pat. 798,920, Sept. 5, 1905. XX., page 1030.

FRENCH PATENTS.

Electrolysis of Alkali Chlorides; Apparatus for the —. H. M. Granier. Fr. Pat. 353,304, March 18, 1905, Under Int. Conv., March 19, 1904.

This invention relates to an apparatus for the direct production of chlorine and caustic alkali from an alkali chloride, and is characterised by the complete separation of the positive and negative liquids by means of "non-filtering" cylindrical water-tight diaphragms, into which are fitted tubular "filtering" diaphragms closed at the top. Between the two sets of diaphragms are interposed rods of iron, which are connected to the negative pole of the apparatus. The filtering diaphragms, containing the negative liquid are arranged in such a manner that the pressure of the liquid may be varied, so as to regulate the rapidity of filtration through the diaphragms. —B. N.

Carbon Bisulphide; Process of Obtaining — after the Carbonisation of Peat to obtain its Carbon, and the Electro-Metallurgical Preparation of the Sulphur Vapour necessary for the Reaction. A. Augier. Fr. Pat. 353,028, April 5, 1905.

The peat, which supplies the carbon for the manufacture of carbon bisulphide, is led up an inclined tube, surrounded by a jacket containing water at 50°—60° C., by means of a helical conveyor; this brings it to the top of the carbonising chamber, which is of truncated conical shape. The peat descends down this on to a large plate, pierced with holes, covered by baffles; it is kept in motion by a rotating vertical shaft on which conical projections are fixed. The carbonising chamber is heated by the heat arising from an electric furnace containing molten iron, which has been obtained from a suitable mineral (e.g., marcasite or chalcopyrite), the sulphur vapour arising therefrom being led through the holes in the plate above mentioned, where they

mingle and combine with the carbonised peat to form carbon bisulphide. A suitable form of apparatus is shown in the accompanying figure: 31 is a portion of the wall of the carbonising chamber, 35 is the plate on to which the peat falls; the electric turnace is shown on the left, where 57 is the receptacle for the molten iron; the sulphur vapour passes through 82, and thence through the holes 83 in 35 into the carbonising chamber. —T. (B).—ELECTRO-METALLURGY.

Calcium. Preparation of Metallic — for Laboratory Purposes. P. Wöhler. Z. Elektrochem., 1905, 11, 612–618.

A LARGE iron crucible contains the fused electrolyte (100 parts of calcium chloride and 17 parts of fluor spar) which has a m.p. of 660° C. A carbon electrode serves as anode and an 8 mm. iron rod as cathode, the latter only just touching the surface of the electrolyte. (See Eng. Pat. 20,655 of 1903; this J., 1903, 1299.) The anode and cathode are about 6 or 8 cm. apart, a current of 40 amperes at 38 volts being employed. The temperature must be kept below the m.p. of the calcium (890° C.). Under these conditions, and with a current density of about 100 amperes per sq. cm. at the cathode, rods of calcium of any desired length can be obtained by gradually feeding up the electrode during the electrolysis, and thus only allowing it just to touch the surface of the electrolyte. The current density at the cathode may vary within wide limits (50 to 250 amperes per sq. cm.) without disturbing the progress of the metal separation. At the anode, however, a limit was observed above which large fluctuations in the current are observed. The author suggests that combination occurs between the chlorine and the carbon anode, and that this may have some bearing on the phenomenon. The current yield in two experiments of short duration is said to have been 82.2 and 84.4 per cent. respectively. The preparation progresses much more satisfactorily in a fresh electrolyte than in one which has been frequently used. —R. S. H.

ENGLISH PATENT.

Furnaces. Impts. in Electric —. P. Girod, Paris. Eng. Pat. 14,333, July 11, 1905.

SEE Addition, of Dec. 24, 1904, to Fr. Pat. 329,822 of 1903; this J., 1905, 740. —T. F. B.

UNITED STATES PATENT.

Furnace. [Electrical] Metallurgical —. G. H. Benjamin, New York. U.S. Pat. 798,258, Aug. 29, 1905.

THE material is fed in at the top of a series of chambers or hearths inclined alternately in opposite directions. It falls by gravity from chamber to chamber, while being exposed to the combustion gases from a tank furnace at the base. In each chamber, means are provided for adding definite charges of fluxes or other combining material, and electrodes are set in each vertical passage connecting the chambers for heating the material electrically, whilst provision is made for carrying the heated gases around such passages. —E. S.

FRENCH PATENTS.

Iron, Steel, Cast Iron, &c.. Process for Covering by Electrolytic Means the Surfaces of Objects of —, with an Adherent Coating of Another Metal. J. Schiel. Fr. Pat. 353,288, Feb. 28, 1905.

THE metal is first rapidly cleaned, deoxidised, and decarburised to a certain depth, by submitting the articles anodes to electric action in an electrolyte containing hydrochloric acid, nitric acid and water, of a density 18° to 20° B., and with a high current density. Plates of carbon, of a greater area than the surface of the anode are used as cathodes, and the surface of the article acquires a porous structure. The surface of the metal and the interior of the pores are then rapidly covered electrolytically with a deposit of finely-divided metal. This is accomplished by making the objects the cathode in a concentrated electrolyte which is a good conductor of electricity, but which is poor in the salts of the metal to be deposited or which is entirely devoid of these salts. Plates of carbon or soluble anodes are used, the surface of which considerably exceeds in area that of the object, and a high current density is employed. The entanglement of the deposited metal with the spongy structure of the object results in a firm adherence of the deposited metal. The objects are afterwards introduced into ordinary galvanic bath depositing metal. —B. N.

Aluminium and its Alloys. Production of Metallic —. A. E. de Souza. Fr. Pat. 353,277, Feb. 3, 1905. Unc. Int. Conv., Feb. 3, 1904.

CRYOLITE, bauxite, hydrargillite, kaolin, or other suitable minerals are treated with nitric, hydrochloric, sulphuric or other mineral acid, or with alkalis, or alkali carbonates, and the alumina which goes into solution, precipitated as hydroxide by means of ammonia; when iron is present in the solution, it must, of course, be separated by carbon dioxide or other suitable means. The aluminium hydroxide is separated by filtration, dried, heated to 120° C., mixed with lime and carbon, electrically reduced, calcium carbide being simultaneously produced. —J. H. C.

Oil. Extracting — from Seeds and the like. T. Silcock and W. A. Silcock, Liverpool, and E. Stephens Hull. Eng. Pat. 1040, Jan. 19, 1905.

CLAIM is made for a process of extraction in which seeds are placed in a rotatable vessel mounted on a hollow shaft divided into compartments by means of a partition. The solvent is introduced at one end of this shaft and passes into the vessel, which is then made to rotate. After the extraction the bulk of the solvent and the extracted oil pass away through an exit pipe, and steam then introduced through the same opening as the solvent in order to cook the seeds and expel the residual solvent. The steam and the vapours pass through perforations in a scraper fixed to the shaft and thence through connecting pipes into the other compartment of the shaft, the end of which is attached to a condenser. —C. A. M.

Oil or other Liquids. Presses for Expressing — from Materials containing them. F. C. Caldwell, Chicago, Ill., U.S.A. Eng. Pat. 8696, April 25, 1905.

IS the type of press claimed, the pressure roller acts with a rotatory and gyratory motion within a pressure chamber.

ch is conical in the case described) provided with edges on its inner walls for the escape of the expressed oil. The material introduced at the top falls between the walls and the conical roller which has spiral corrugations on one side at the upper part and all round near the bottom. As the roller revolves vertically, the gyratory motion causes the seed to be pressed by the plain surface against the side of the chamber, whilst the spirally corrugated surface subsequently removes the crushed substance and carries it downwards. When the material reaches the lower portion of the chamber where the corrugations go right round the roller, it is driven into a large discharge chamber, whence it can be removed without interrupting operation of the press.—C. A. M.

FRENCH PATENT.

Antimony Compounds for Use as Pigments, &c.; Process of the Preparation of —. E. Chatillon. Fr. Pat. 356,655, April 20, 1905.

A mixture of antimony ore and combustible material is heated in a cupola furnace, the latter being connected with a number of exhaust-condensers, where the fumes from the furnace are treated with sprays of water holding solution or suspension sulphides, carbonates, sulphites, hydroxides of the alkalis or alkaline earths. These combine with the sulphur dioxide, carbon dioxide and gaseous antimony oxide to form various coloured pigments. By heating the ore with an excess of coke and in a closed vessel, a yellow colour is produced. To obtain a violet colour, the gases coming from the furnace are passed through a chamber heated to a temperature of 900° C. and then condensed. Compounds in sulphur may be added to the charge in the cupola.—W. P. S.

Col-Resin Oils [Kauri and Manila]. L. Schmoelling. Chem.-Zeit., 1905, 29, 955–956.

The volatile oil obtained in the preparation of kauri oil is a bright yellow mobile liquid with a pleasant

smell. It is soluble in most organic solvents except light petroleum. The constants are: Sp. gr., 0.8677 at 15° C.; acid value, 3.0; saponification value, 149; iodine value (Waller), 288.9. It distils easily between 150 and 160° C. and contains pinene. The volatile oil from manilla copal has a rose colour, which disappears on exposure. Its constants are: Sp. gr., 0.9069 at 15° C.; acid value, 28.3; saponification value, 45.7; iodine value (Waller), 230.4. The acid and saponification values decrease if the oil is exposed. It distils between 60 and 250° C. and contains an aldehyde. No evidence of the presence of limonene or pinene was found. (See also this J., 1901, 729.)—F. S.

UNITED STATES PATENTS.

Hides; Process of Treating —. F. J. Oakes, New York. U.S. Pat. 798,070, Aug. 23, 1905.

CLAIM is made for the use of sulphur and putrefying albuminous matter in a bath in which the hides are treated before tanning. The amount of each substance used in this process may be 5 per cent. of the weight of the hides.—W. B. H.

Hides; Process of Treating —. F. J. Oakes, New York. U.S. Pat. 798,293, Aug. 29, 1905.

THE process consists in soaking hides in a bath containing sulphur, a carbohydrate such as glucose, and an alcoholic ferment such as yeast. The amount of the principal materials (sulphur and glucose) used may be 5 per cent. of the weight of hides treated.—W. B. H.

Hides; Process of Treating —. F. J. Oakes, New York. U.S. Pat. 798,294, Aug. 29, 1905.

THE hides are soaked in an aqueous bath containing sulphur and a putrefying excrementitious substance.—W. B. H.

Leather and Leather Cloth; Manufacture and Waterproofing of —. P. C. D. Castle, Bebington. U.S. Pat. 798,951, Sept. 5, 1905.

SEE Eng. Pat. 2167 of 1901; this J., 1905, 36.—T. F. B.

FRENCH PATENTS.

Tanning; Process of —. J. R. Riviere and P. E. Verrone. Fr. Pat. 350,026, June 29, 1904.

SKINS, after liming and pickling, are rapidly dried and then treated with an infusion of dung from horses (or other herbivorous animals), made by digesting 100 kilos. of the dung in 100 litres of water for 24 hours, and afterwards adding a further 100 litres of water every two hours until the whole measures 500 litres.

The tannage is commenced in the drum or paddle, using a weak solution of the horse dung infusion, which is gradually strengthened until thorough penetration through the skins has been secured; the time required is from 2 to 3½ hours.—M. C. L.

Chromium Protoxide; Application of Salts of — in Tanning, with a view of Obtaining a Deposit of Chromium Sesquioxide on the Fibres of the Hide. R. Berthou. Fr. Pat. 353,418, April 17, 1905.

NEUTRAL solutions of chromous salts when exposed to the air are oxidised, either a mixture of chromium sesquioxide and a chromic salt, or a basic chromium salt being formed. In presence of animal tissues, such as hides, the basic chromium salt is decomposed, chromium sesquioxide being deposited on the fibres of the hide and a neutral chromic salt left in solution. The present patent relates to the employment of chromous salts in tanning, and it is stated that the leather produced is superior to chrome-tanned leather produced by the usual processes. The chromous salt may be prepared either by a chemical or by an electrical method. In the first case a solution containing 10 per cent. each of chrome alum and sodium chloride is passed

through a closed vessel containing granulated zinc, then through the vat containing the hides to be tanned, and then again through the zinc box, and so on. In working by the electrical process, a 5 per cent. solution of pure chromic chloride, prepared in any suitable manner, is subjected to electrolysis with the aid of a low E.M.F. in a cell furnished with a porous pot. The electrolyte is circulated through the tanning vats, and then again through the electrolytic cell, to which from time to time suitable quantities of chromic chloride are added.—A. S.

Glass Process for the Manufacture of —, from Bones, H. B. P. & S. Co., O. Schneider, Fr. Pat. 350,017, June 24, 1904.

THE process consists in treating bones, pieces of hide and other similar substances with a phosphate, preferably sodium phosphate, followed by an after treatment with dilute sulphuric acid. It is claimed that the sodium sulphate and phosphoric acid produced during the treatment, do not render the finished product less transparent. M. C. L.

XVI.—SUGAR, STARCH, GUM, Etc.

UNITED STATES PATENTS.

Starch Process of Obtaining Soluble —, R. Hartwig, Assignor to Siemens and Halske Aktienges., Berlin. U.S. Pat. 798,509, Aug. 20, 1905.

IN this process, soluble starch, especially maize starch, is obtained by subjecting dry raw starch at ordinary temperatures (50° to 86° F.) to the action of an excess of gaseous chlorine for four to eight days, or until perfectly soluble in hot water.—W. B. H.

FRENCH PATENTS.

Masse culées [Sugar]: Continuous Preparation of —, H. Roy, Fr. Pat. 353,317, March 29, 1905.

THE process of withdrawing the finished masseculite without interrupting the work of the pan is effected by means of the principle described in Fr. Pat. 337,227 (see this J., 1904, 616; 1905, 980) in which the boiling syrup is circulated outside the pan by means of a pump, re-heater and telescopic tubes. When the charge has been concentrated to the final point, the supply of feed syrup being cut off, the telescopic circulating tubes are raised above the level of the masseculite, the suction tube being always at a higher level than the return tube. The feed-supply valve is then opened and the new syrup is boiled as a separate charge on the top of the layer of finished masseculite, circulating independently of the latter. Meanwhile, a valve is opened in the bottom of the pan through which the lower layer of finished masseculite is withdrawn without disturbing the boiling of the top layer of thinner syrup. A sufficient residue of masseculite remains in the pan to serve as a graining bed for the new charge.—J. F. B.

Sugar Juice: [Electrolytic] Clarification of —, R. J. Thomas and W. F. S. Boyce, Fr. Pat. 353,368, April 20, 1905.

THE hot juice is subjected to the action of an electric current, and the coagulated impurities are removed by decantation or filtration.—J. F. B.

Sugars: Process of Refining —, J. V. P. Lagrange, H. Le Secq des Tournelles and B. Gaud, Fr. Pat. 353,639, April 22, 1905.

Raw sugar of No. 3 quality, clean except for contamination with molasses, is purified either by "maceration" or "precipitation." In the maceration process, the sugar is placed in a closed centrifugal apparatus, and treated whilst in motion by a current of air saturated with expanded steam. The saturated air passes from the outside of the layer of sugar to the inside, and liquefies the molasses dried on the grain, so that it is whirled away. In the deposition process for obtaining fine grain sugar, a syrup of very high density is produced by the use of a temperature gradually rising from 115° to 120° C., and the

product so obtained is crystallised systematically in one of the crystallising malaxeurs commonly employed for the purpose of crystallising refinery masseculites.—J. F. B.

XVII.—BREWING, WINES, SPIRITS, Etc.

Malt: Increasing the Brewery Yield of Extract from — by Separate Mashing of the Grits. G. Merz, W. f. Braun, 1905, 22, 493—495.

THE exhausted grains of the brewery always retain from 0.5 to 1.4 per cent. of undissolved extract (calculated the weight of the malt) in the form of the steely unmodified points of the corns. By adopting the principle of separating the steely points from the hulls before mashing, about 50 per cent. of this loss of extract may be avoided. The mechanical difficulty of separating the steely grits from the hulls, without unduly damaging the filtering properties of the latter, can be accomplished with the aid of a Seeker Sieves of suitable meshes are inserted in a four-roller machine, these first separate the hulls, together with the firmly adherent steely grits from the normal grist and flour, and then deliver the two last into separate compartments of grist-case. The hulls and steely grits are then milled a second time in such a manner that the hulls are not broken up, whilst the steely particles of grit are brought into a suitable condition for separation by the sieves. The hulls are then delivered into the compartment containing flour, and the steely grits are mixed with the normal grist. In the brew-house, the mixed grist is mashed in hot water for 15 minutes to effect a preliminary saccharification, and the mash is then boiled for 30 minutes, in the absence of hulls permitting a prolonged boiling without ill effects. This boiled gelatinised mash is then discharged into a plain infusion of the mixed hulls and flour previously prepared in the mash-tun, and the whole is saccharified in the usual manner.—J. F. B.

Maltoxydase. W. Issajew, Z. physiol. Chem., 1905, 331—350; Chem. Centr., 1905, 2, 688.

AN extract of malt made with 50 per cent. glycerol contains both a direct acting oxydase and an indirect peroxidase. Malt oxydase somewhat resembles Bertrand's lacase, it is weaker in its action and does not react with tyrosine. It acts only on auto-oxidisable bodies, intensifying their oxidation, e.g., on pyrogallol, *p*-aminophenol, &c. Pyrogallol is oxidised to purpurogallin only when hydrogen peroxide is present, similarly, the guaiacum reaction is only shown in presence of hydrogen peroxide. Malt oxydase is weakened by the action of high temperatures, but is not entirely destroyed even by steam of 1½ atmos. pressure. It acts best in neutral media. Mercuric chloride and tannin destroy its activity, and 20—40 per cent. alcohol weakens it considerably. A dilute solution of manganous sulphate is without influence, but stronger solutions are harmful; this is a further differentiation from lacase. The oxydase is active during the germination of the barley; its activity increases up to the eighth day, and then remains constant. Malt extract contains small quantities of easily oxidisable substances, the greater part of which are precipitated by 80 per cent. of alcohol.—J. F. B.

Wines: Ageing of —, P. Malvesin, Bull. A. C. Chim. Sucr. Dist. 1905, 23, 130—133.

THE deposits eliminated from wine during ageing are composed of crystals of potassium bitartrate and certain mineral salts, also of coagulated colouring matter, tannates, fatty matters, and micro-organisms. In order that any artificial ageing process may simulate the natural process, the formation and elimination of all these matters must be ensured. This elimination can only be produced properly by the alternate or simultaneous influences of oxidation and reduct. Experience has shown that the most suitable oxidising agent is the air; ozone, oxygen and hydrogen peroxide produce special flavours and effects which cannot be regarded as equivalent to natural ageing. A successful ageing process must also include: an increase of bouquet due to the formation of aldehydes, esters and acetals; a sufficient degree of "décoloration."

due to the disappearance of a portion of the original acidity during esterification and to the precipitation of a portion of the tannins by the action of the oxygen of the air, and cold; double decompositions which convert bitartrates into neutral tartrates. These various actions constitute a complex process which cannot be effected in a single operation, but only by a series of appropriate treatments, which, however, may be made to proceed each other rapidly in practice. Any process depending on the introduction of foreign substances into wine, or on contact between the wine and such reagents defective in practice owing to the abnormal flavour which is thus imparted.—J. F. B.

Formic Acid in the Distillery; Use of ———. H. Lange. Z. Spiritusind., 1905, 28, 341-342.

The author draws attention to the extremely favourable results obtained in the distillery by the addition of formic acid to the acidified [lactic acid] yeast mash. The formic acid in small doses stimulates the fermentative activity of the yeasts, preserves the diastase in an active condition throughout the fermentation, and protects the mash from the action of acid-forming bacteria, whereby maximum yields of alcohol are obtained. The fermentation of mashes containing formic acid starts more quietly than usual and is more uniform in intensity; a very characteristic feature of such mashes is the exceptional vigour of the secondary fermentation. This uniformity of fermentative intensity enables the tuns to be filled higher than is usually the case. For a fermentation tun of 100 litres capacity, 50—60 c.c. of pure formic acid is used. In practice the strong formic acid is diluted the ratio of 1 part to 8 parts of water. The yeast mash is prepared and acidified in the usual manner; after the mash is cooled to 37°—38° C., 100 c.c. of the diluted formic acid are added for every 100 litres of mash, and the yeast is pitched at a suitable temperature. After the yeast has been run in this manner through three successive fermentations, the dose of formic acid is raised to 200 c.c. per hectolitre, at which it is maintained for six further fermentations; the final proportion of formic acid, viz., 100 c.c. of diluted acid to 100 litres of mash is then employed constantly. When employing the full proportion of formic acid it is advisable to raise the temperature at which the yeast is pitched by 1.5°—2° C.—J. F. B.

Beer Wort; Processes of Preparing ———. L. Rübsam, Bamberg, Germany. Eng. Pat. 23,597, Nov. 1, 1904.

Eng. Pat. 347,590 of 1904; this J., 1905, 341.—T. F. B.

Beer Wort; Process for Separating By-Products of Alcoholic Fermentation from ———. O. Pamp, Halle on the Saale, Germany. Eng. Pat. 5930, March 21, 1905.

The mash or wort is delivered from a distributor into a series of two (or more) worms of a dephlegmator. In this part of the apparatus it is heated to a temperature of 75° C. and is kept under slight pressure by a constriction or jet of steam in the discharge pipe. The latter leaves the bottom of the dephlegmator and supplies the wort to the top of a carbon dioxide separator. This contains a number of

concave and convex trays, over which the top of the trays, heated to a temperature of 70° C., whereby the liberation of the carbon dioxide is facilitated. The liberated carbon dioxide, charged with alcohol, escapes through a pipe at the top of the separator. By collecting and cooling the gas, the alcohol is separated, and may be used for methylation purposes.—W. P. S.

Aerated Waters, Alcoholic and other Drinks; (containing Formates). J. C. Richardson, London. Eng. Pat. 17,749, Aug. 16, 1904.

The patentee claims the manufacture of beverages such as aerated waters, wines, spirits and other liquids, to which have been added from 5 to 15 grs. of sodium formate per pint. The formates of the other alkalis or of alkaline earths may also be used.—W. P. S.

Spirits; Preliminary Treatment and Ageing of ———. C. A. Petersen-Schepelern, Vejle, Denmark, and C. W. Schwanenlüzgel, Copenhagen. Eng. Pat. 13,022, June 23, 1905.

To promote the oxidation of fusel oil, from 10 to 20 c.c. of 3 per cent. hydrogen peroxide and 1 grm. of powdered blood-charcoal are added to each litre of spirit. After standing for 24 hours, the rectification is proceeded with in the usual manner. An alternative way is to treat the spirit with 30 c.c. of hydrogen peroxide per litre and then to store it for three or four months in barrel, when it will be fit for use.—W. P. S.

Arsenic; [Electrolytic] Method of Separating ——— from Liquid Food Materials whether used as Liquid or Treated or Combined with other Materials to Produce a more or less Solid Food. O. G. C. L. J. Overbeek. Eng. Pat. 24,174, Nov. 8, 1904. XVIII., page 1027.

Grape Marcs; Extraction of Cream of Tartar from ———. G. Tarulli. Fr. Pat. 353,459, April 6, 1905. XX., page 1030.

GERMAN PATENT.

Spirit Distilling Apparatus; Control Device for the Receivers of ———. E. G. Hager. Ger. Pat. 160,636, Oct. 21, 1904.

The control device is for the purpose of indicating any illegal withdrawal of untaxed spirit at the outlet of the condenser connected to the distilling apparatus. If the liquid in the still be heated too strongly, the flow of spirit to the condenser becomes too rapid, and the condensed liquid rises under the bell above the outlet of the condenser, and eventually flows out between the bell and the lower support or stand, and can then be removed illegally. The control device claimed, registers the number of periods of excessive heating, and also the highest level attained by the spirit under the bell. It consists essentially of an apparatus fitted with two floats, of which one remains fixed in the highest position to which it rises, whilst the other at definite levels sets free balls which are directed into an open basin or cavity, where they can be counted.—A. S.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS.

(1.)—FOODS.

Palm Oils [Coconut Oil] and Butter; Contribution to the Knowledge and Determination of the Volatile Fatty Acid in ———. O. Jensen. Z. Untersuch. Nahr.- u. Genussm., 1905, 10, 265—283.

In these investigations, the volatile fatty acids concerned were separated from one another by a method of fractional

precipitation of their silver salts. The properties of these acids, and their relative proportions in butter and cocoanut oil are discussed at some length, and for the detection of small quantities of cocoanut oil in butter the determination of the "caprylic and capric acid values" is recommended. As a preliminary to the separation of the volatile fatty acids with silver nitrate, the solubility of the silver salts of the acids, both in water and in the presence of a definite quantity of silver nitrate per 100 c.c., was determined, and the results for butyric, caproic and caprylic acids are given in the following table:—

Silver salt of:	Grams. dissolved in:	
	100 c.c. of water.	100 c.c. of N/20 silver nitrate solution.
Butyric acid	0.489	0.347
Caproic acid	0.089	0.029
Caprylic acid	0.018	0.005

With the aid of these figures, the proper degree of concentration for any particular separation can be chosen, and the correction for the influence of any excess of silver nitrate made. The solubility of the three higher volatile fatty acids themselves has been carefully determined. Capric acid is insoluble in water at 15° C., whilst 100 c.c. of water dissolve 0.079 grm. of caprylic and 0.872 grm. of caproic acid respectively. Though caproic acid is so much more soluble than caprylic acid, it is noteworthy that if a saturated solution of caproic acid be shaken with a little caprylic acid, the acid value of the solution falls rapidly, and the liquid is changed into a saturated solution of caprylic acid, whilst most of the caproic acid is thrown out of solution. The presence of butyric acid on the other hand has no influence on the solubility of either of these acids.

The percentage of butyric and caproic acids in pure butter-fat varies very considerably and the author has collected the figures of the Reichert-Meissl value from different laboratories in the chief butter-producing countries. To obtain from the Reichert-Meissl value, the relative proportions of butyric and caproic acids present, the author has worked out the following formulae:—

$$C = \frac{(R.M.V. - 1.7)}{1 + x} \cdot \frac{100}{96}$$

$$\text{and } B = \frac{(R.M.V. - 1.7)}{1 + x} \cdot \frac{100}{88}$$

where C and B are the caproic and butyric acid values respectively, and x is the ratio B/C. To obtain the real proportion of butyric to caproic acid in the butter-fat itself, this value B/C must be multiplied by $\frac{96}{88}$ or 1.09.

—A. S.

When this calculation is made, it is found that the ratio B/C in all these butters of different origin varies from 1.3 to 4.4 with an average of 2.8, and the figures show that roughly the proportion of caproic acid is greater in mild than in more severe climates, though there are occasional exceptions to this rule. The average percentage of the two acids in all the butter-fats taken is 3.92 per cent. of butyric, and 1.88 per cent. of caproic acid.

Cocoanut oil contains no butyric and little caproic acid, but chiefly caprylic and capric acids, and owing to this

small proportion of soluble fatty acids, the Reichert-Meissl value varies very greatly with the weight of fat taken. In estimating the percentage of cocoanut oil in an adulterated sample of butter, this fact makes the generally accepted theory that a mixture of "A" parts of fat of R.M.V. "R" with "a" parts of a fat of R.M.V. "r" must have itself the R.M.V. $\frac{AR + ar}{A + a}$, a source of

considerable error. The author has prepared mixtures of butter-fat with 50, 25 and 10 per cent. of cocoanut oil, and submitted them to a thorough examination. The R. value was determined in the three samples, and by the use of the above formula, only 40, 16 and 5 per cent. of cocoanut oil were found, instead of 50, 25 and 10 per cent. respectively.

Determinations of the Polenske, Kirschner, iodine and saponification values are all useful for the identification and rough estimation of cocoanut oil adulterated butter, but for the detection of small quantities (less than 10 per cent.), the determination of the caprylic acid by precipitation with silver, and also of the insoluble capric acid, is strongly recommended. In the case of capric acid, the "capric acid value" i.e., the acid expressed in N/10 c.c. per 5 grms. of fat increases by 1.3 for an addition to a butter-fat of 5 per cent. of cocoanut oil, a rise that is well outside the limits of experimental error.—A. N. C.

Wheat Flour; Testing — for Commercial Purposes
H. Snyder. J. Amer. Chem. Soc., 1905, 27, 1068—107

In testing wheat flour for commercial purposes, determinations of the moisture, ash, total nitrogen, gliadin nitrogen, degree of granulation, and absorptive capacity should be made. The presence of more than 13 per cent. of moisture tends to induce fermentation. The proportion of ash is a measure of the commercial grade of the flour. The first and second grades of "patent" flour invariably contain less than 0.48 per cent. of ash, "straight grade" flour rarely contains more than 0.55 per cent., while the first and second "clear grades" may contain 0.8 and 1.75 per cent. of ash respectively. The amount of total nitrogen in flour is useful only as a general index of bread-making value. A low nitrogen content, less than 1.5 per cent., indicates deficiency in gluten, and this results in a lower absorptive capacity of the flour, lack of expansion in the loaf, and poorer physical properties of the bread. On the other hand, flours containing more than 13 per cent. of proteid substances (N x 6.25) do not, as a rule, have improved bread-making qualities. The percentage of gliadin in flour is of use in determining the grade of different grades of flour milled from the same wheat showing different proportions of gliadin. The bread-making value of a flour can be accurately determined only by comparative bread-making tests. The results of analyses of some samples of flour are given in the following table:—

ENGLISH PATENTS.

Flour; Process for Restoring to White — certain Properties and Materials or Ingredients Lost in Milling for use in the Manufacture of Bread, Cakes, Past Puddings and other Articles of Food in which Flour is or may be used. H. Roberts, London. Eng. F. 23,576, Nov. 1, 1904.

To every 80 lb. of white flour are added 0.75 lb. each of potassium and magnesium phosphates, 0.5 lb. of sodium

osphate, and 2 oz. of calcium phosphate, together with 1.5 oz. of soluble proteid, such as dry, powdered milk proteid.—W. P. S.

Seals and Grain; Means for Bleaching — C. Crocker, Owensboro, Ky., U.S.A. Eng. Pat. 6939, April 1, 1905.

Grain is treated with a current of air which has been passed through a mixture of nitric acid and metallic per.—W. P. S.

Ascorbic; [Electrolytic] Method of Separating — from Liquid Food Materials, whether used as Liquid or Treated or Combined with other Materials to Produce a more or less Solid Food. O. G. C. L. J. Overbeck, Grimsby, Eng. Pat. 24,174, Nov. 8, 1904.

Liquids, such as those employed in brewing or in the manufacture of food extracts, are passed through a vessel which are placed a number of copper plates, alternately rising nearly to the top and bottom of the vessel. These plates form electrodes, and, when connected with a current of low voltage, cause any arsenic present in the liquid to be electrolytically deposited.—W. P. S.

Starch Powder; Manufacture of Soluble — A. Glas, Berlin. Eng. Pat. 7982, April 14, 1905. Under Int. Conv., May 17, 1904.

Fr. Pat. 347,739 of 1904; this J., 1905, 432.—T. F. B.

Amin Preparations; Process for Producing Blood — L. Langer, Friedrichsberg, Germany. Eng. Pat. 7830, April 12, 1905.

IRONISED animal blood is treated with organic iron salts soluble in water, such as calcium glyceryl-phosphate or phospholactate, in presence of inorganic iron compounds, such as calcium carbonate, oxide, hydroxide, or phosphate. For example, 4 kilos. of calcium glyceryl-phosphate are dissolved in 250 kilos. of ironised ox blood. About 12 kilos. of calcium hydroxide, containing "from 40 to 50 per cent. of $(OH)_2$ " are then added. In a few hours the whole is set, when it is powdered and washed with water. The amount of organically combined iron in the washed product is stated to be about 33.3 per cent.—W. P. S.

Ice-cream Substitutes such as Margarine and the like; Manufacture of — K. Mann, Zurich. Eng. Pat. 15,311, July 25, 1905. Under Int. Conv., Nov. 30, 1904.

Up to 100 parts of vegetable or animal fats or oils are thoroughly incorporated in a closed vessel with from 50 to 100 parts of milk and a suitable quantity of colouring matter. The mixture is then caused to ferment by the introduction of kephir fungus or kephir milk. When fermentation is complete, the fat is freed from the milk, washed, and worked as usual. The product is claimed to have the flavour and odour of natural butter.—W. P. S.

FRENCH PATENTS.

Ice-cream; Treatment of —, with Carbon Dioxide or other inert Gas, either alone or mixed with an Oxidising or Reducing Agent. M. A. Eybert and C. P. Eybert. Fr. Pat. 353,179, April 10, 1905.

During the bolting process the flour is surrounded with an atmosphere of dry, cold carbon dioxide or other inert gas. The flour may, at the same time, be bleached by passing either a reducing or an oxidising gas with the carbon dioxide.—W. P. S.

Preparation of Grape Marcs as Cattle Food; Recovery and Utilisation — L. M. V. Chaboissier. Fr. Pat. 353,333, April 12, 1905.

CRUSHED grape marcs are deficient in sugar, but rich in proteids, other carbo-hydrates and fat. These marcs are dried, preferably at an initial temperature sufficient to destroy the germs of putrefaction; the dried marcs are then incorporated with saccharine substances such as molasses, beetroot slices or wheat-bran, and utilised as cattle food.—J. F. B.

(B).—SANITATION; WATER PURIFICATION.

FRENCH PATENT.

Air for Respiration Purposes; Apparatus for Preventing Breathed Out — M. Bamberg, F. Dock, and F. Wanz, all of Vienna. Eng. Pat. 9185, May 2, 1905.

IMPROVEMENTS in the apparatus described in Eng. Pat. 8865, 1904 (this J., 1904, 833) are claimed. The peroxides are filled into vessels which are afterward hermetically closed, and the apparatus is so constructed that these vessels may be readily put into and removed from the same. After the contents of the vessels have been exhausted, fresh ones may be substituted without exchanging any other parts of the apparatus. The vessel containing the peroxide is placed between two movable frames provided with perforating crowns and connected by tubes with the mouth-piece of the apparatus. A valve is placed on the tube leading to the mouthpiece, by means of which only one peroxide vessel is in communication with the mouthpiece at the same time. —W. P. S.

UNITED STATES PATENTS.

Sewage or Drain Water; Apparatus for Carrying out Bacterial Purification of — O. Kremer, Gross Lichterfelde, Germany. U.S. Pat. 798,908, Sept. 5, 1905.

SEE Eng. Pat. 20,889 of 1904; this J., 1901, 1158.—T. F. B.

Water; Method of Purifying — [by Distillation]. H. F. Hodges and J. Kuen, Philadelphia, Pa., Assignors to American Water Purifying Company, Delaware. U.S. Pat. 798,964, Sept. 5, 1905.

HIGH-PRESSURE steam is passed through a layer of coke and then conducted into a condenser submerged in water contained in an evaporating chamber. The steam arising from the heated water is led into a second condenser surrounded by water, and so on through a succession of evaporators until the last produced steam is reduced to the desired temperature and pressure. Additional steam may be admitted to each condenser. The gases liberated during the evaporation are conducted away, whilst the distillate from each condenser is cooled by passing it through a chamber surrounded by the incoming water, and is finally filtered through charcoal.—W. P. S.

(C).—DISINFECTANTS.

ENGLISH PATENT.

Chlorine; Generation and Application [as Disinfectant] of — J. Hargreaves. Eng. Pat. 20,835, Sept. 28, 1904. VII., page 1012.

GERMAN PATENTS.

Carbon Bisulphide Emulsions, Miscible with Water, suitable for Destroying Insects on Plants. Chem. Fabr. in Billwärd, vorm. Hell und Stahmer A.-G. Ger. Pat. 161,266, Oct. 17, 1903.

EMULSIONS of carbon bisulphide, miscible with water, and suitable for the destruction of phylloxera, &c., on plants, are prepared by mixing with the bisulphide some organic compound soluble in water, e.g., molasses, dextrin or "schlempe." For example, 750 kilos. of carbon bisulphide, 166 kilos. of dextrin and 84 kilos. of water may be rubbed into an emulsion.—T. F. B.

Aluminium Acetate [Antiseptic]; Process of Preparing an Insoluble Basic — by Heating Aluminium Acetate Solution. R. Reiss. Ger. Pat. 160,348, April 30, 1904.

A BASIC aluminium acetate, quite insoluble in water, is obtained by heating, under pressure, a solution of aluminium acetate (containing at least 5 per cent. of the salt) either alone or with acetic acid. The product is a mildly astringent, non-poisonous, antiseptic powder. It is of constant composition, and the yield is satisfactory. The products obtained by simply heating aqueous solutions are of variable composition, and not always insoluble.—T. F. B.

XIX.—PAPER, PASTEBOARD, Etc.

Paper Tensile Test: Influence of Cellulose on the Result.
R. Naumoff. *Papier Zeit.*, 1905, 30, 2802.

In expressing diagrammatically the results obtained for the resistance of paper to folding, by means of the Schopper folding machine, the relations between the springs holding the paper are plotted as a scissure, whilst the number of double folds which the paper resists is plotted on the ordinate axis. The resulting curves have the form of hyperbolæ. The author points out that these hyperbolæ may be reduced to straight lines by plotting the numbers proportionally to their logarithms, which may be done on paper ruled for that purpose. The inclinations of the straight lines so obtained indicate the law according to which the resistance of the particular paper varies with the tension, whilst any point lying outside the main line may be recognised as a experimental error and corrected as such; lastly, when a large number of tests have to be made, it is sufficient to determine with care the resistance at two different tensions and to interpolate the other values from the line obtained on the diagram by joining the two points. —J. F. B.

Celluloid or Nitric Cellulose Compounds: Process for Rendering — Non-inflammable. W. C. Parkin and A. Williams, Sheffield. Eng. Pat. 22,381, Oct. 18, 1904.

SEE Fr. Pat. 347,446 of 1904; this J., 1905, 344. —T. F. B.

Celluloid Waste: Process and Apparatus for Utilising — [Recovery of Camphor]. E. Garbin, G. Gérard and C. Gerard, Genoa. Eng. Pat. 10,319, May 16, 1905.

The celluloid waste is cleansed in a warm bath of slightly alkaline water, and is then treated either by a dry or a wet process. The dry process consists in packing the celluloid in a tube perforated at one end, which communicates with a condensing tube and receiver. The charge is ignited by inserting a heated plug in a small hole at the closed end of the tube. A slow combustion of the celluloid is thus induced, whereby camphor and nitric acid distil over and are collected. In the wet process the celluloid is decomposed by means of a solution of caustic alkali and the camphor is distilled off by steam, purified in a bath of sodium bisulphite, and finally collected in cold water. At the end of the process of decomposition, the acid liquid from the dry process is mixed with the alkaline liquid from the wet process, the camphor is distilled off, and the sodium nitrate is recovered. —J. F. B.

UNITED STATES PATENT.

Pulp from Sugar-cane, Cornstalks, Sorghum, and Analogous Pithy Stalks: Process of Manufacturing Soft Absorbent — and Product of such Process. V. Drewsen, New York. U.S. Pat. 798,887, Sept. 5, 1905.

Peat Half-Staff [for Paper Manufacture]: Manufacture of —. A. Kirner. Fr. Pat. 353,538, April 19, 1905.

The peat is broken up and washed through a sieve, the large pieces being collected for further treatment, whilst the finer portions suspended in the water are agitated in a special vessel and discharged into a chamber containing two or more reciprocating sieves placed one above the other. The matters collected on the different sieves are transferred to horizontal roller-mills, in which the pressure of the rolls is regulated according to the coarseness or fineness of the material fed between them, the coarser material receiving the heavier pressure. Each pair of rolls revolves at a differential speed, so that the fibrous material is thoroughly resolved and converted into half-stuff. —J. F. B.

Copper Oxide: Process for Recovering —, and for the Preliminary Treatment of Textiles in the Manufacture of Artificial Textile Fibres. R. Linkmeyer. Fr. Pat. 353,187, April 10, 1905. —V., page 1011.

GERMAN PATENT.

Half-Staff [Paper]: Process of Making —. E. Berghoff. Ger. Pat. 160,651, Dec. 24, 1903.

The waste liquors from the manufacture of sulphite cellulose are used in this process, which consists in heating small pieces of wood, sawdust, &c., in the liquors, where they are said to be so far disintegrated that they can very easily be converted into fibre suitable for paper making by mechanical means. The papers prepared from the resulting half-stuff are said to be characterised by extreme toughness. —T. F. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

Zirconosulphuric Acids. R. Ruer and M. Levin. Z. anorg. Chem., 1905, 46, 449–455.

THE authors have previously shown that an aqueous solution of normal zirconium sulphate behaves as though the zirconium formed part of a complex anion, so that the substance has possibly the constitution $\text{H}_2\text{SO}_4 \cdot \text{ZrO}_2 \cdot \text{SO}_4$. They now find that by dissolving zirconium hydroxide in an aqueous solution of the sulphate, a series of compounds can be obtained, all of which seem to be zirconosulphuric acids containing complex ions similar to, but containing more zirconium oxide than, those of the solution of normal sulphate. —J. T. D.

Zirconium Oxysulphide. [Detection of Zirconium]. R. F. T. XXIIL, page 1033.

Mercuric Acetate: Action of Aldehydes and Acetone on —. M. A. Lasserre. J. Pharm. Chim., 1905, 2, 246–249.

WHEN aldehyde is added to an aqueous solution of mercuric acetate, and the solution allowed to stand, plates of mercurous acetate separate after a few hours. The same action takes place if, instead of acetic aldehyde, formic, propylic or butylic aldehyde is added; precipitation is also brought about by the aldehyde equivalents. Alcohols and acetone give no precipitate under the same conditions. If sodium hydroxide be added to an aqueous solution of mercuric acetate and aldehyde cooled to 0°C , a grey precipitate is formed. The precipitate is insoluble in water or alcohol, but is soluble in mercuric acetate solution, and has the formula, $\text{CH}_3\text{COH} \cdot \text{O} \cdot \text{Hg} \cdot \text{O}$. If excess of sodium hydroxide be added to an aqueous solution of mercuric acetate and acetone, and the solution allowed to stand, an amorphous reddish precipitate is formed; this substance is probably an addition compound of 1 mol. of acetone with 2 of mercuric oxide. —C. E.

Barium Cacodylate: Preparation of —. A. Armand. Boll. Chim. Farm., 1905, 44, 485–488. Chem. Centr., 1905, 2, 751.

Barium cacodylate, which is widely used in the preparation of other cacodylates, can be obtained in a pure condition by the following method:—A mixture of equal parts of crystallised barium hydroxide and cacodylic acid is finely ground in a mortar, and barium hydroxide solution is added gradually until the mixture is faintly alkaline to phenolphthalein. The solution is decanted, filtered, after standing for several hours, rendered neutral by adding a small crystal of cacodylic acid, evaporated in vacuum at a low temperature, and the residue heated at 115°C for at least three hours in a well-closed oven in presence of potassium hydroxide, quicklime, and calcium chloride. After cooling in the oven, the dry hygroscopic product is rapidly powdered, and stored in coloured bottles with well-fitting stoppers. —A. S.

Phellandrene; Synthetic and Natural — J. Kondakow and J. Schindelmeiser. *J. prakt. Chem.*, 1905, 72, 13—196.

Purposes of comparison, *d*-phellandrene was isolated from the oil of *Phellandrium aquaticum* and treated with perchloric acid in acetic acid. On fractional distillation, a solid monochloride, $C_{10}H_{17}Cl$, was obtained, boiling at 6° at 11 mm., and melting near 110° C. This substance closely resembles artificial camphor and solid ethyl chloride.—F. S.

Mandarin Oil. E. Berté and S. Gulli. *Chem. and Druggist*, 1905, 67, 445—446.

MANDARIN oil is obtained by hand pressure with a thin knife from the slight and green peel of the fruit of *Citrus madurensis*, *C. deliciosa*, or *C. bigaradia sinensis*, such as mandarins, the yield being about 400 grms. of oil from 1000 mandarins. The oil is a golden-yellow liquid with a characteristic slight bluish fluorescence, which becomes more pronounced when the oil is diluted with alcohol (see this J., 1900, 848, 1237). The pure oil has the following constants:—Sp. gr. at 15° C., 0.851—0.858; optical rotation, $+67^{\circ}$ to $+73^{\circ}$; b. pt., 171° C. The greater part of the commercial mandarin oil sold at a relatively low price, is stated to be composed of a mixture of more or less sweet or bitter orange oil (arade), lemon oil or terpenes, and mandarin oil. Adulteration can be detected by determination of the refractive constants and by the fractional distillation method of Soldaini and Berté (this J., 1897, 266; 1898, 1160; 1904, 881; compare also this J., 1896, 925); mandarin oil gives a distillate with a rotatory power 10 degrees higher, and a residue with a rotation equally or more than that of the original oil. Some analytical results obtained with genuine mandarin oil are given, also (see table) some obtained with adulterated oils.

—A. S.

Oil; Constituents of — O. Wallach. *Nachr. k. Ges. Wiss. Göttingen*, 1905, 1—2. *Chem. Centr.*, 1905, 2, 674.

Essential oil from broad-leaved sage (*Salvia grandifolia*) has the sp. gr. 0.9084 at 15° C.; and $n_D^{20} = 1.496$. It contains *l*-pinene, cineol, *l*-camphor, and a hydrocarbon which has somewhat similar properties to phellandrene. On treatment with nitrous acid, a compound melting at 85° C. is formed.—A. S.

Schinus Mollé, L.; Phellandrene from the Essential Oil of — O. Wallach. *Nachr. k. Ges. Wiss. Göttingen*, 1905, 2—3. *Chem. Centr.*, 1905, 2, 674.

Phellandrene from the essential oil of *Schinus mollé*, (sp. gr. 0.829 at 15° C.; $n_D^{20} = +57^{\circ}$), after being distilled with steam, yields a nitrite, which can be separated by fractional crystallisation from acetone into two portions melting at 111° and about 96° respectively. The nitro-phellandrene prepared from the nitrite gives on reduction only carvotanacetone, and the hydrocarbon of *Schinus mollé* must therefore consist chiefly of α -phellandrene.—A. S.

Eucalyptus Globulus; Occurrence of Pinene in the Essential Oil of — O. Wallach. *Nachr. k. Ges. Wiss. Göttingen*, 1905, 2, 674—675.

The authors isolated from the highest stage portion of the oil of *Eucalyptus Globulus*, an alcohol, $C_{10}H_{18}O$, which, after purification by means of its acid picrate, was found to consist of the optically active monolinear pinocarveol. It boiled at 92° C. under 12 mm. pressure, had the sp. gr. 0.9745 at 20° C., $n_D^{20} = 1.49630$, $[\alpha]_D^{20} = -52.45^{\circ}$ in 12.75 per cent. ethereal solution. —A. S.

Dextro- and Levo-Fenchone; Semicarbazones of — O. Wallach. *Nachr. k. Ges. Wiss. Göttingen*, 1905, 6—12. *Chem. Centr.*, 1905, 2, 675.

Fenchone reacts only very slowly with semicarbazide, but its semicarbazone can be obtained by mixing together solutions of 10 grms. of pure fenchone in 50 c.c. of alcohol, and of 10 grms. each of semicarbazide hydrochloride and sodium acetate in 20 c.c. of water, and allowing the mixture to stand at the ordinary temperature for at least two weeks. On pouring into water a solution of the semicarbazone in the excess of fenchone, separates, from which the fenchone can be removed by distillation with steam. If the raw material used for the preparation of the semicarbazone is a crude fenchone, containing other constituents capable of reacting with semicarbazide, the fenchone semicarbazone does not crystallise so readily. In a *l*-fenchone from thuja oil, the presence of *l*-camphor, which reacts with semicarbazide much more readily than fenchone does, was detected, and it was found that treatment with semicarbazide solution affords an easier means of separating camphor from fenchone, than oxidation with nitric acid. The occurrence of camphor in crude fenchone points to the presence of esters of *l*-borneol in thuja oil.—A. S.

Formaldehyde; Hydrogen Peroxide Method of Determining — J. K. Haywood and B. H. Smith. *NXII.*, page 1039.

Pharmaceutical Compound [Salicylic Acid Monoglycol Ester]; Manufacture of a New — H. E. Newton,

London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 4055, Feb. 27, 1905.

THE monoglycol ester of salicylic acid,

is prepared by esterifying 40 parts of salicylic acid and 80 parts of ethylene glycol with 3 parts of sulphuric acid (60 B.), by heating at 100° C. for 24 to 36 hours. The product is diluted, made alkaline with sodium carbonate and extracted with ether; the dried ethereal solution is distilled *in vacuo*, the ester being obtained at first as an oil of b. pt. 173° C. (15 mm.), which solidifies to a solid, melting at 37° C. It is resolved into glycol and salicylic acid by alkali hydroxides. It is stated to be of value for the treatment of rheumatism. — T. F. B.

Violts; Manufacture of Substances with the Colour of — A. Maschmeyer, Amsterdam, Eng. Pat. 13,347, June 28, 1905. Under Int. Conv., July 22, 1904.

CITRAL is condensed with an ester of a monohalogenated acetic acid in presence of an alkali alcoholate. The condensation product may be regarded as a citrylidene-alkoxyacetic ester having the constitution: —

in which R and R' are variable alkyl radicals. The aliphatic compounds so produced are converted into their cyclic isomers which exist in two modifications, the α - and β -series are predominant when concentrated sulphuric acid at 0° C. is employed, whilst the α -series are formed principally when hot dilute acids are used. These cyclic compounds possess an odour of violets. — J. F. B.

Celluloid Waste; Process and Apparatus for Utilising — [Recovery of Camphor]. E. Garbin, G. Gérard and C. Gérard, Eng. Pat. 10,319, May 16, 1905. XIX., page 1028.

Lubricants; Impts. in — L. A. A. Hennequin and G. J. B. Cayeux, Eng. Pat. 11,679, June 3, 1905. III., page 1008.

UNITED STATES PATENTS.

Dialkylbarbituric Acid; Process of Making — J. Altschul, Assignor to Act.-Ges. f. Anilinfabr., Berlin. U.S. Pat. 798,863, Sept. 5, 1905.

SEE Eng. Pat. 8302 of 1904; this J., 1905, 289. — T. F. B.

Oxalic Acid and its Derivatives; Method of Reducing — by Electrolysis. E. von Portheim, Prague, Austria-Hungary. U.S. Pat. 798,920, Sept. 5, 1905.

GLYOXALIC acid, its esters and amides, may be obtained from compounds containing the oxalyl radical (C_2O_2), by dissolving the compound to be treated in dilute sulphuric acid, and then electrolysis the solution at a low or moderate temperature in the cathode compartment of an electrolytic apparatus. — B. N.

FRENCH PATENTS.

Tartar, Cream of; Process for Producing — The California Products Co. Fr. Pat. 353,276, Feb. 2, 1905.

SEE U.S. Pat. 783,524 of 1905; this J., 1905, 290. — T. F. B.

Grape Mares; Extraction of Cream of Tartar from — G. Tanulli. Fr. Pat. 353,459, April 6, 1905.

THE mares are lightly packed in diffusion vessels in which they are treated, either simultaneously or alternately, with steam and with water, which may be introduced either from above or below, with internal distributors, if desired, so that they penetrate through all parts of the mass. The liquors are distributed and raised or lowered and successively discharged as they become richer in cream of tartar. The first liquors, rich in extractive matter, are separated from the subsequent liquors, the latter being kept at the boiling point and used for further extractions, whilst the former are treated for the recovery of the tartar. After the extraction of the cream of tartar, the mares are exhausted with a mineral acid in a similar manner in order to dissolve the calcium tartrate. — J. F. B.

Dialkylbarbituric Acids; Process of Preparing — Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 353,459, Feb. 7, 1905. Under Int. Conv., March 29, 1904.

SEE U.S. Pat. 789,902 of 1905; this J., 1905, 749. — T. F. B.

Camphor from Isobornol; Process of Preparing — C. F. Boehringer und Soehne. First Addition, dated April 1, 1905, to Fr. Pat. 352,888, March 31, 1905.

SEE Eng. Pat. 28,035 of 1904; this J., 1905, 249. — T. F. B.

GERMAN PATENTS.

Sulphur Derivatives of Mineral Oils; Process for Producing Sulphonated — G. Hell and Co. Ger. Pat. 161,663, Dec. 23, 1900. III., page 1008.

Tannin with Formaldehyde and Urea or Urethane; Process of Preparing Condensation Products of — A. Winkler. Ger. Pat. 160,273, Nov. 6, 1903.

IN addition to the condensation of tannin with formaldehyde and urea described in Eng. Pat. 23,549 of (this J., 1905, 103), this specification covers the condensation of tannin substances, formaldehyde and urethane in which the tannin combines with the anhydroformyl-urethane formed as intermediate product; methylenediurethane is also obtained as a product of the condensation. — T. F. B.

Bornylendiamine; Method of Preparing — P. Dorn. Ger. Pat. 160,103, Nov. 13, 1903.

BORNYLENEDIAMINE (diaminocamphane) may be prepared by reducing the oxime of amino-, isonitroso- or isonitro-camphor, either with sodium and alcohol with sodium amalgam, or electrolytically. The base is extracted by ether, and is obtained as a waxy substance of b. pt. 246° C. and very easily soluble in water. It is poisonous, and a powerful antipyretic. — T. F. B.

Cotarnine Hydrochloride and Ferric Chloride; Process of Preparing a Double Salt of — A. Voswinkel. Ger. Pat. 161,400, Dec. 3, 1903.

A DOUBLE salt is obtained by the action of 1 mol. of ferric chloride on 2 mols. of cotarnine hydrochloride in presence of a suitable solvent, at the ordinary temperature. The double salt is precipitated as orange plates, which are filtered off, washed with alcohol and dried. The salt has a m. pt. of 104°–105° C., is easily soluble in water and dilute alcohol, sparingly so in absolute alcohol. The aqueous solution is composed by heating into a precipitated cotarnine and iron oxychloride. When used medicinally it is stated to combine the properties of cotarnine and ferric chloride. — T. F. B.

4,5-Diamino-2,6-dioxypyrimidines; Process of Preparing — E. Merck. Ger. Pat. 161,493, March 3, 1904.

4-AMINO-5-ISONITROSO-2,6-DIOXYPYRIMIDINES can be converted into the 4,5-diamino compounds by reduction with metals in acid solution; the acid is found not to act as a hydrolysing agent on the product, as no hydroxy-isonitrosobarbituric acid is produced. The reduction has only been found possible previously by boiling with ammonium sulphide solution, when the isolation of the product was a difficult matter. In the present process sparingly soluble derivatives are simply filtered off, whilst when easily soluble compounds are obtained, the mother salt is removed by addition of ammonia. — T. F. B.

Endiminotriazoles; Method of Preparing — E. Merck. Ger. Pat. 161,235, July 27, 1904. Addition to Ger. Pat. 159,692, March 6, 1904.

INSTEAD of treating the triarylaminoguanidine with carbon dioxide as in the process of the principal patent (see this J., 1905, 814), it is condensed with an aldehyde, an aldehyde resulting aminodihydrotriazole oxidised to an endiminotriazole with a suitable oxidising reagent. The preparation of the following compounds is described: — Endanilphenyltriazole, endaniltriphenyltriazole and phenyl-p-tolylendotoluidotriazole (the latter from phenyl-triarylaminoguanidine and formaldehyde). — T. F. B.

Quinazoline Derivatives; Process of Preparing — S. S. Gabriel and J. Colman. Ger. Pat. 161,601, July 23, 1904.

QUINAZOLINE is converted into alkylquinazolinium salts by the ordinary methods for producing quaternary salts. The products of quinazoline with methyl and ethyl iodide, bromide, and iodide are described. These salts are stated to strongly lower the blood pressure. —T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

ENGLISH PATENT.

Photographic Printing Papers or Surfaces; Preparation — K. Pillanz, Linz a/D., Germany. Eng. Pat. 1,077, May 26, 1905.

THE paper is coated with a soluble layer of a suitable coloring matter, dried, and then coated with a layer of romated albumin, gelatin, fibrin, peptone, dextrin or other colloid substance. When dry, the paper is ready for use as in the ordinary "carbon" or "gum bichrome" processes. It is stated that, using such papers, brilliant shadows, with properly graduated half tones, are produced. —T. F. B.

FRENCH PATENTS.

Photographic Papers; Self-Adhesive — E. Mallet. Fr. Pat. 353,189, April 10, 1905.

THE back of the photographic paper is coated with gelatin or similar adhesive substance, which is softened by hot water soluble in, the solutions employed for the treatment of the paper; such papers can be mounted immediately after the final washing by simply pressing them on to the necessary support. —T. F. B.

Photographic Paper suitable for the Application of Water Colours. L. Robiesek. Fr. Pat. 353,349, April 13, 1905.

INSTEAD of using a sized paper, an unsized paper be employed for the preparation of photographic papers by using with a gelatin emulsion, the resulting photographs are stated to be easily tinted with water colours. —T. F. B.

Photographs in Colours; Direct Process for Producing — A. Blachorowitsch. Fr. Pat. 353,420, April 13, 1905.

A LAYER of glass or sheet of celluloid is coated with a layer of gelatin containing a "palpable yellow color"; when dry, it is sensitised in a solution of potassium bichromate, and placed in a receptacle from which the air is exhausted, when it is covered with a solution of celluloid or similar substance and allowed to dry; the process is twice repeated, with the exception that, in the first case, a "carminc powder" and, in the second case, powdered Prussian Blue is used instead of the yellow color; the resulting plate is exposed in a camera, immersed in cold water for a short time, and then in hot water, until the latter commences to be coloured; the layers of gelatin are then stripped off and their development is completed in hot water. The three films are now dried successively, and in register to a gelatin-coated plate, the plate being dried, and the celluloid, &c., dissolved away between the application of each film. "negatives" thus formed are utilised for printing

on paper prepared and developed in the same manner as the plates. (Compare Eng. Pat. 22,988, 1904, this J., 1905, 104.) —T. F. B.

GERMAN PATENT.

Flash Light; New — H. E. Newton, London. Pat. Farbentab., vorm. F. Bayer and Co., Elberfeld, Germany. Eng. Pat. 24,987, Nov. 17, 1904.

FLASHLIGHT powders which give a highly uniform flame, and which do not evolve large quantities of smoke on ignition, are produced by adding to aluminum or magnesium (or a mixture of these) a salt of perboric acid, or tungstic acid or a tungstate. The tungstate flashlights are stated to burn more slowly than the ordinary flashlights; thus, a mixture of equal parts of magnesium and sodium tungstate will burn for several seconds. —T. F. B.

XXII.—EXPLOSIVES, MATCHES, Etc.

Nitric Acid; Manufacture of — O. Guttmann. Chem.-Zeit., 1905, 29, 934-935.

Winteler (this J., 1905, 924) expressed doubt whether the data given by the author in the last German edition of Muspratt are not out of date, and whether European works make the same stringent demands for purity and high strength of acid that American works do. Those data hold at the present time, and comparison of the mixed acids quoted by Winteler with those used in European works shows that the demands of the latter are quite as stringent as those of American works. The author still holds—though the practice of many works is based on an opposite view—that beyond a certain point, increase in concentration of either acid improves neither the yield nor the quality of the nitroglycerin obtained. The actual yield of nitroglycerin is always at least 10 per cent. below theory, but the causes of this are so many that but little influence on the yield can be exerted by higher concentration or greater freedom from nitrous acid in the nitric acid used; the British Government Works at Waltham Abbey obtain as high a yield as any, though they use an acid containing up to 1.5 per cent. of nitrous acid.

A slight excess of sulphuric acid is not so disadvantageous as Winteler suggests. It need not be so great as to give rise to difficulties of storage, while yet enough to secure the advantage of readily fusible bisulphate; the latter can, by appropriate means, be easily granulated when poured from the retort, so that grinding is unnecessary if it is to be used for hydrochloric acid manufacture. The foaming of which Winteler speaks can be kept within very manageable limits by proper arrangement of the retorts and management of the distillation. —J. T. D.

Nitric and Sulphuric Acids; Properties of Mixtures of — A. Saposchnikow. Z. physik. Chem., 1905, 53, 225-234.

THE author has extended his investigation (see this J., 1905, 635) to the case of mixtures of pure 100 per cent. sulphuric acid, H₂SO₄, and nitric acid, of sp. gr. 1.40, containing 65.3 per cent. of nitric acid and 34.7 per cent. of water. The chief results are shown in the following table:—

Sp. gr. 1.40.	Nitric Acid	Sulphuric Acid.	Percentage Composition of Mixture.			Vapour Pressure.	Nitrogen Content of Vapours.	Sp. gr. at 25°/25°.	Specific Conductivity in reciprocal ohms at 25°.
			HNO ₃ .	H ₂ SO ₄ .	H ₂ O.

—	—		—	—	—	—	—	1.8441	0.0248

Nitric acid of sp. gr. 1.40 is thus affected in a similar manner to acid of sp. gr. 1.48 by addition of sulphuric acid. The acid of sp. gr. 1.40 is used in the manufacture of different kinds of nitrocellulose containing up to 12 per cent. of nitrogen, and also in the preparation of picric acid and other products. When mixed with sulphuric acid, it is distinctly less active than the acid of sp. gr. 1.48, but by preparing a mixed acid of suitable composition, it is probable that highly-nitrated products could be prepared with it. For example, the mixture No. 9 (see table) is not much different in composition from the mixed acid with which Lunge and Bebie prepared an insoluble pyroxylin containing 13.2 per cent. of nitrogen. Experiments on the effect of addition of water to the mixed acids, showed that a mixture having a composition between the limits represented by mixtures Nos. 9 and 10 is practically unaffected by addition of small quantities of water. For nitrating purposes, therefore, a mixed acid should be used having a composition between these limits.

In the following table the results of some experiments on pure nitric acid of various strengths are given:—

Percentage Composition of Acid.		Sp. gr. at 15° C.	Vapour pressure of HNO_3 at 15° C. in mm.	Percentage of Nitrogen in the Vapour.
HNO_3 .	H_2O .			
98.00	2.00	1.5100	46.2	23.75
92.93	7.07	1.4970	42.6	23.5
88.65	11.35	1.487	39.7	23.05
82.10	17.90	1.462	16.64	22.62
78.10	21.90	1.453	9.40	22.32
65.30	34.70	1.400	1.90	19.32

—A. S.

UNITED STATES PATENT.

Blasting Powder.—W. A. Gill, Tarrytown, N.Y. Assignor to Rendrock Powder Co., New York. U.S. Pat. 798,780, Sept. 5, 1905.

The compound consists of about 80 per cent. of potassium chlorate, 18 per cent. of resin, and 1 per cent. each of asphalt and of nitrated wood fibre.—E. S.

FRENCH PATENTS.

Explosives; Process for Prevention of Humidity of —. Soc. Gen. pour la Fabrication de la Dynamite. Fr. Pat. 349,992, June 15, 1904.

It is proposed to add kieselguhr to explosives containing hygroscopic constituents, for the purpose of absorbing any moisture originally present or subsequently taken up on storage. If kieselguhr is present, it is stated that the explosive constituents proper remain in a dry state. An example given is ammonium nitrate (70 parts), nitroglycerin (29.1 parts), nitro-cotton (0.9 part) and kieselguhr (3 parts).—G. W. McL.

Explosives; Process for the Manufacture of New Detonating and Propellant —. G. Schulz and F. Gehre. Fr. Pat. 352,990, March 9, 1905.

CLAIM is made for a series of explosives containing the di- and trinitro-derivatives of mesitylene and pseudo-cumene. A detonating explosive is produced by incorporating these bodies with an oxygen-bearer, such as ammonium nitrate, with or without the addition of finely-divided iron or copper. These metals are claimed as a substitute for magnesium and aluminium, already used in this type of explosive. A smokeless propellant is produced by mixing the above nitro-bodies with nitro-cellulose.—G. W. McL.

Explosive; New —. P. de Golovine. Fr. Pat. 353,299, March 15, 1905.

The explosive, which is stated to be suitable for military

purposes, and also for use in mines and quarries, consists of a mixture of potassium chlorate (39 parts), yellow potassium borate (18), ammonium chloride (2), coke or wood charcoal (2) and glycerin or refined petroleum (2 parts). The solid constituents are finely powdered and passed through a fine sieve. The potassium chlorate is then intimately mixed with the coke or charcoal, ammonium chloride and potassium borate added in the order given, and the whole triturated to a homogeneous mass with the glycerin or petroleum.—A. S.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS, ETC.

Calorimeter; Junkers' —. T. Immenkötter. J. Gasbeleucht, 1905, 48, 780—783.

The capabilities of this instrument (this J., 1895, 631) have been extended so as to deal with (1) poor (2) liquid fuels.

(1) Cheap generator gases, &c., with a calorific value below 900 Cal. are difficult to burn in the ordinary way. By burning the gas with the smallest quantity of oxygen in an oxyhydrogen burner, instead of using air, good results were obtained with a mixture giving only 670 Cal. This is sufficient; as the poorest gas in present use have an average calorific value of 800 Cal. per cb. m.

(2) The difficulty of burning heavy oils has been overcome by the use of pressure in the reservoir. A slightly modified "Primus-burner" was found to give very satisfactory results, and by means of a special apparatus the most suitable pressures for various oils were obtained. The results below were obtained with a nozzle-tube of 3 mm. diameter.

	Boiling temperature.	Pressure.	Time of burning per test.
Gasoline	30°C.	mm. 820	30"
Benzine	62°—74°C.	450	30"
Petroleum (motor-oil, b.pt., 160°—293°)	{160° before 163° after	450	30"
Heavy oil	413°C.	130	40"

About 50 per cent. by volume of the quantity of oil taken is burnt. For spirit a nozzle-tube of 1.1 mm. diameter and a pressure of 60 mm. of mercury were required. With the modified apparatus shown (see Fig.), the whole burner and oil reservoir can be suspended by the life-edges from the arm of a balance throughout the experiment, in order to ascertain the weight of oil consumed. The calorimeter is so arranged that the burner, after lighting, can be introduced and then the apparatus hung on the balance-arm. A small manometer is attached to the reservoir and the necessary pressure obtained by bicycle pump. During an experiment the pressure remains almost constant.

The advantages claimed are (1) the requisite air is sucked into the calorimeter by the flame itself (2) there is uniform combustion of all constituents of the oil, if the latter is a mixture. Even the heaviest oils can be successfully tested.—F. SPOV.

ENGLISH PATENT.

Density or Specific Gravity of Liquid and or Semi-liquid Material [Slip, Glaze, Potters' Liquid, &c.]; Apparatus for use in Ascertaining the —. J. M. James, Stoke-on-Trent. Eng. Pat. 18,305, Aug. 24, 1904.

A CONTAINING vessel *a* provided with a row of perforations to ensure that it is always filled to a constant level, has a graduated scale *b* fastened upon the projecting back piece. A hydrometer or weighted float rod *e* is immersed in the liquid contained in the vessel *a* and is kept in an upright position by the projecting cheek-pieces *f* and the "latch" *d*, which are so arranged that the free vertical movement of the hydrometer *e* is not impeded. The position of the top of the float rod indicates the density which is read off from the scale. The apparatus may be fastened to a stand and immersed in the liquid or semi-liquid or it may be filled by pouring into the top in the ordinary way. —W. H. C.

GERMAN PATENT.

Thermo-Element consisting of an Alloy of Antimony and a Metal or Alloy fusible with difficulty; Method of Joining the Two Components of a Thermo-Element. A. W. Schmitt and Co. Ger. Pat. 160,305, Nov. 18, 1903.

Is the manufacture of a thermo-element consisting of a high-melting metal or alloy and an antimony alloy, the strip of the high-melting body is heated to the melting point of the antimony alloy, and is then rubbed firmly and evenly with a piece of antimony or antimony alloy till it is covered with a thin but adherent and uniform coating of the latter, without the formation of a film of oxide. The hot coated strip of high-melting metal or alloy is then pressed into the antimony alloy which is to form the second component of the thermo-element, and in this way a good junction is obtained without the use of a solder.—A. S.

INORGANIC—QUALITATIVE.

Zirconium Oxychloride [Detection of Zirconium]. R. Ruer. Z. anorg. Chem., 1905, 46, 456–459.

If from an aqueous solution of a zirconium compound the hydroxide be precipitated by ammonia, washed, removed from the filter, dissolved in hydrochloric acid, the solution evaporated in the water-bath almost to dryness, taken up with a little water, and concentrated hydrochloric acid be added, drop by drop, to the cooled solution, zirconium oxychloride is precipitated. On warming, this dissolves, and is deposited again, on cooling, in the form of silky crystals of very characteristic appearance under the microscope. This can be used (especially by comparison with crystals prepared from a known source) as a reaction to identify zirconium.—J. T. D.

INORGANIC—QUANTITATIVE.

Aluminium; Iodometric Determination of —, in Aluminium Sulphate and Chloride. S. E. Moody. Z. anorg. Chem., 1905, 46, 423–427.

THE reaction of potassium iodide and iodate with aluminium sulphate

utilised by Stock as the basis of a gravimetric method for determining aluminium (this J., 1900, 276), also allows of a volumetric determination by titrating the liberated iodine. A measured quantity (25 c.c. of approximately N/10 solution) of the aluminium salt (containing no free acid) is placed in a Voit flask, and 19 c.c. of solution of potassium iodate (30 grms. in the litre) with 1 gram. of potassium iodide are added; the flask is then connected with a Drechsel flask containing 3 grms. of potassium iodide dissolved in water, a stream of hydrogen is passed through the apparatus, and the mixture is heated till practically colourless (15–25 minutes). The iodine collected in the Drechsel flask, and any small quantity still contained in the evolution flask, are then titrated with thiosulphate. Results are accurate with aluminium chloride or potassium alum: with ammonium alum the solution in the receiver must contain free acid sufficient to neutralise any ammonia carried over.—J. T. D.

Platinum Metals; Technical Determination of the —. J. Nordenskjöld. Svensk Kemisk Tidskrift, 1905, 54. Chem. Centr., 1905, 2, 790.

OF the platinum metals, iridium and rhodium are not dissolved by *aqua regia*. Osmium is oxidised by concentrated *aqua regia*, but can be removed in the form of the volatile perosmic acid. Palladium, which is also soluble in other acids, is removed by a preliminary treatment. The dilute platinum solution is treated with metallic magnesium, warmed for a quarter of an hour

on the water-bath, and filtered. The precipitate is washed, gently ignited, again washed after moistening with hydrochloric acid, ignited in a current of hydrogen, allowed to cool in an atmosphere of carbon dioxide, and weighed. The residue is then treated with dilute *aqua regia*, the platinum re-precipitated by magnesium, washed well, finally, after moistening with hydrochloric acid, ignited and weighed. On the first occasion the finely-divided platinum metals must not be ignited too strongly or for too long a time, or an iridium-platinum alloy, insoluble in *aqua regia*, may be formed.—A. S.

ORGANIC—QUALITATIVE.

Dyestuffs on Animal Fibres; Identification of —.

A. G. Green, assisted by H. Yeoman and J. E. Jones.
J. Soc. Dyers and Col., 1905, 21, 236—243.

IN the scheme of analysis proposed by the author, use has been made, in the first place, of stripping tests, and in the second place, of a modification of the method suggested by A. G. Green for the analysis of dyestuffs in substance (this J., 1893, 3, 71), depending on the behaviour of the different reduction products on oxidation. The modifications consist in using sodium hydrosulphite (in place of pipe dust) for the reduction and a persulphate for chromic acid for the re-oxidation. It is found that the leuco compounds remain, in great part, attached to the fibre, whilst the "splitting-products" of azo dyestuffs are entirely removed therefrom by washing.

The following is the general behaviour of the various groups of dyestuffs on animal fibres:—

Decolourised by hydrosulphite.			Not decolourised, but changed to brown. Original colour restored by air or persulphate.
Colour restored on exposure to air.	Colour not restored by air, but on oxidation with persulphate.	Colour not restored either by air or persulphate.	
Azines, Oxazines, Thiazines, Indigo.	Triphenylmethane group.	Nitro-, Nitroso-, and Azo-groups.	Pyrene, Acridine, Quinoline, and Thiazol groups. Some members of Anthracene group.
			Most dyestuffs of the Anthracene group.

Having ascertained both the dyeing group and the chemical relationship of the colouring matter, and taking the shade also into consideration, the question is usually narrowed down to a single representative or to a choice between a very few closely related dyestuffs. For distinguishing between these, the behaviour with concentrated sulphuric acid or strong hydrochloric acid can be frequently employed. In the appended tables the subdivision of the groups has been usually omitted as unnecessary, but is given in a few instances (see Table II.) in order to illustrate the general method. For additional confirmation it is well to compare the sample both as to shade and reactions with a dyed pattern of the dyestuff to which it is believed to correspond.

Reagents.—The following reagents are employed:—Dilute ammonia (1:100); aqueous alcoholic ammonia (1 c.c. of ammonia, 50 c.c. of alcohol, 50 c.c. of water); 5 per cent. acetic acid; dilute alcohol (1:1); dilute hydrochloric acid (1:10); caustic soda (10 per cent.); hydrosulphite A (10 per cent. solution of formaldehyde-sodium hydrosulphite); hydrosulphite B (200 c.c. of hydrosulphite A and 1 c.c. of glacial acetic acid); a cold saturated solution of potassium persulphate; a 5 per cent. solution of crystallised sodium acetate.

Procedure.—The reactions are performed in test-tubes with pieces of the material about $\frac{3}{8}$ in. to 1 in. square, which

are covered with about 1 in. to $1\frac{1}{2}$ in. of the reagent. In making "stripping tests" the degree of stripping is judged by comparing the depth of shade remaining with that of original pattern. It is found advantageous in boiling with dilute acetic acid and dilute ammonia to repeat extraction, as a better stripping is thereby obtained and also with acid dyestuffs any staining of the cotton by the first strong extract is avoided. In testing with dilute ammonia or sodium acetate, the piece is placed in a test-tube with a somewhat smaller piece of white mercerised cotton cloth, and boiled for the time prescribed. If the shade is a pale one the size of the sample should be increased and that of the cotton diminished. The dilute ammonia is replaced by aqueous alcoholic ammonia in case of the violet and black dyestuffs (Tables III. & VII.), as in these cases the acid dyestuffs are less easily extracted, and the cotton is more liable to be stained than the wool. In making reduction tests, the sample is boiled from one-quarter to one minute with the hydrosulphite, then rinsed well under the tap, and allowed to lie on white paper for an hour or so. With most dyestuffs which form air-oxidisable leuco compounds, the colour returns immediately or in a few minutes, but with others a longer time is required. The reaction is accelerated by exposure to ammonia vapour. If the colour does not return, the pattern is heated to boiling in a test-tube with a little water, and potassium persulphate is added drop by drop, carefully avoiding an excess. If this also fails to cause any return of colour, the dyestuff is to be regarded as an azo or nitro compound. The depth of the restored colour varies greatly in different cases; whilst with some dyestuffs the colour reappears with nearly its original depth with others (probably on account of the greater solubility of their leuco compounds) only a light shade may return. Safranin and its azo derivatives yield on reoxidation the leuco compound a violet colour. This is due to condensation of the leuco-safranin with the formaldehyde present in the hydrosulphite NF.

The reactions given in the annexed analytical table were mostly ascertained upon the wool fibre, but from a number of tests which were also conducted for comparison upon silk, there seems no reason to believe that the latter fibre will exhibit any variations in behaviour. On the other hand, cotton and vegetable fibres require rather different treatment, which it is proposed to deal with in a later paper.

Mixtures.—Although it is not intended to deal fully with the detection of mixtures, a few general principles may be mentioned which will be found useful by those who wish to extend the scheme to such cases. If a mixture consists of two or more dyestuffs of the same chemical and dyeing group, it will behave as a whole similarly to a single dyestuff, though sufficient differences will usually exist in the rate of solution or of attack by the group reagents to render it possible to distinguish or even to separate the constituents. Thus a green, consisting of a mixture of an acid azo yellow with an acid azo blue, will be distinguishable upon careful reduction with hydrosulphite, since the azo blue will be reduced first, and the shade will therefore change from green to yellow before it is decolourised. Neither colour will return on oxidation. Further, if such a compound shade be extracted fractionally with dilute ammonia, the yellow is generally stripped first, and may be transferred to another piece of wool for subsequent tests. Mixtures of colours belonging to different groups will usually exhibit at once the diverse composition. For example, a navy blue shade dyed with Patent Blue and an azo orange will, on reduction, first change to bright blue, then become colourless, and upon reoxidation with persulphate the blue alone will return. If a mixture of an azine, oxazine, or thiazine dyestuff with a triphenylmethane colour has been employed, only the first will return upon exposure of the leuco compound to air, the latter being also restored on treatment with persulphate. Fractional extraction of the fibre with dilute alcohol or dilute acetic acid can also be employed in many cases to effect a separation or partial separation of the dyestuffs, the extracted colour being then transferred to fresh wool or silk and separately tested.

Hydroaliphatic B				Lasso or no colour is stripped—Acid, Salt, or Mordant dyestuff. Keep the ammoniacal extract.															
Not decolourised or only very slightly. Treat fibre with conc. H ₂ SO ₄				Much colour is stripped but cotton remains white:—Acid dyestuff. Boil with hydroaliphatic B.															
Green fluorescent solution:— Auridine group.	Colourless solution. Boil with dilute HCl (1:10).	Fibre and solution pale yellow, decolourised.	Decolourised. Colour is not restored by air or hy persulphate:— Azo group.	No change of colour.	Becomes colourless.	Becomes violet or red.	Becomes violet or red.	Not affected or slightly changed by exposure to air or more quickly by persulphate:— Thiazol group.	Decolourised. Colour not restored by air or by persulphate:— Azo group.	The cotton is stained:—Salt dyestuff. Boil with hydroaliphatic B.					The cotton remains white:—Mordant dyestuff. (Confirm by testing ash for metallic mordants). Boil with hydroaliphatic B.				
										Green fluorescent solution:— Auridine group.	Colourless solution. Boil with dilute HCl (1:10).	Fibre and solution pale yellow, decolourised.	Decolourised. Colour is not restored by air or by persulphate:— Azo group.	Not affected:— Flavone and Ketone group.	Colour changed to yellowish brown:— Alizarine group.	Decolourised and colour not restored by air or persulphate:— Azo group.

ORGANIC—QUANTITATIVE.

Sulphur and Halogens in Organic Substances; The Crucible Method for Determining —, S. S. Sadtler, J. Amer. Chem. Soc., 1905, 27, 1188—1192.

For the determination of sulphur, halogens and phosphorus in organic substances, especially volatile substances, the following method has been found to give good results. The platinum apparatus used is shown in the accompanying illustration. The outer crucible *C* is furnished with a tightly-fitting lid, and has, in its bottom, an indentation *B* in order to extend the highly-heated zone into the inner crucible *L*. The latter has small rings of platinum *L* soldered to the wide closed end to keep it in position within the outer crucible. The open end of the inner crucible is made as thin as possible, and it fits about midway between the indentation *B* and the outer crucible. The substance is weighed out into the smaller crucible, and if it is a liquid, is covered with a sufficient quantity of a mixture of equal parts of dried magnesia and sodium carbonate to absorb it. The crucible is then filled nearly to the top with the same mixture, and magnesia added till the crucible is completely filled. A layer of freshly-ignited white asbestos *A* (see Fig.) is placed on the bottom of the larger crucible, which is then placed over the smaller one, the whole inverted, and the determination completed in the usual manner.—A. S.

Oil in Water from Condensing Engines; Determination of —, J. McFarlane and J. Mears. Chem. News, 1905, 92, 108.

Two litres of the water (or 1 litre if the amount of oil exceed 0.4 gr. per gall.) is heated "nearly to boiling" with 5 c.c. of a solution of ferric chloride, prepared by dissolving 10 grms. of iron in 200 c.c. of hydrochloric acid, oxidising with nitric acid and diluting to 1 litre. Ammonia is now added in excess, and the solution boiled for two minutes and filtered through a filter paper which has been extracted with ether. The precipitate (which is said to contain all the oil) is washed with hot water, dried at 100° C., and extracted with ether in a Soxhlet extractor, the ethereal extract being subsequently evaporated and the oil weighed.—T. F. B.

Glycerol; Comparison of Methods of Determining — in Fats, Soaps and Glycerin Preparations. F. Schulze, Chem.-Zeit., 1905, 29, 976—980.

THE author has continued his series of comparative determinations (this J., 1905, 943), and gives tables of the results obtained with fats, soaps and preparations containing glycerin. Here, again, he finds the permanganate method unreliable, whether carried out as originally devised by Benedikt and Zsigmondy or by Herbig's or Mangold's modifications. Although serviceable results may be obtained in this way it is impossible to be certain whether the oxidation is complete, or has gone too far. The acetin method has not given concordant figures in the author's hands, and he considers it essential to take the mean of several determinations if the method is still to be employed. The bichromate method is stated to give too high results as a rule, and to obviate this the figures

should be lowered by 10 per cent., or Hehner's bichromate solution taken as corresponding to more glycerol (74.86 grms. of $K_2Cr_2O_7 = 11$ grms. instead of 10 grms.) Gaunter's method of measuring the carbon dioxide evolved generally yields too low results, and the value should be increased by 2 to 3 per cent. The bichromate method appears to be only reliable in the absence of phosphoric acid. Zeisel and Fanto's iodide method is regarded as the best, but is too expensive for factory work and should only be used as a means of checking the volumetric bichromate method.—C. A. M.

Glycerol in Liqueur Wines; Determination of —, X. Rocques, Ann. Chim. anal. appl., 1905, 10, 306—309 Chem. Centr., 1905, 2, 930.

IN order to distinguish between genuine liqueur wine and those prepared by addition of alcohol to unfermented must, a determination of the glycerol present is useful. If the proportion of glycerol be less than 0.1 grm. per 100 c.c., the liqueur must be regarded with suspicion. For the determination of the glycerol, the following method has been found trustworthy by the author. 200 c.c. of the liqueur wine are evaporated on the water-bath to a syrupy consistence, and the residue triturated with quantity of finely-powdered quicklime equal to that of the sugar present. After allowing the mixture to stand for half an hour, 200 c.c. of 96—97 per cent. alcohol are added gradually with continuous stirring, and, after further half an hour, the whole is filtered, and the filtrate washed with alcohol. The filtrate is acidified with a alcoholic solution of tartaric acid, a few small pieces of pumice are added, and the greater portion of the alcohol is distilled off. The residue (15—20 c.c.) is well mixed in a shallow dish with 3—5 grms. of quicklime and 10 grms. of fine sand, and dried *in vacuo* in an exsiccator. The dry mass is treated in a closed flask with 80 c.c. of ethyl acetate and 20 c.c. of alcohol for two hours, with vigorous agitation at intervals. The mixture is then filtered, and a measure portion of the filtrate (75 c.c.) evaporated to dryness *in vacuo* over sulphuric acid, and the residue weighed after three days.

Ethyl acetate recommended as a solvent by Trilla dissolves per 100 grms., only 1.34 grms. of glycerol at 20° C. whereas the mixture of ethyl acetate and alcohol used by the author dissolves 8.06 grms. of glycerol, without an appreciable quantities of other constituents of the wine.

—A. S.

Malt; Determination of Yield of Extract in —, Bergdolt, Z. ges. Brauw., 1905, 28, 597—601, 617—620.

THE author has studied comparatively three methods for the determination of the yield of extract from malt when mashed under the standard laboratory condition.

(1) The "proportionality" method, adopted as the standard by the Berlin Congress of 1903, the concentration of the wort being based on the weight of water added plus the moisture of the malt.

(2) The "two filtrates" method. The cooled mash from 50 grms. of malt is made up to a weight of 450 grms. 250 c.c. of the wort are filtered off and the residual mass is mixed, without loss, with 250 c.c. of water and again filtered. The extract in 100 grms. of air-dry malt is then

calculated by the formula: Malt Extract = $2 \frac{250E}{E - e}$

where *E* is the percentage of extract in the first filtrate and *e* is that in the second filtrate.

(3) The absolute "washing out" method. The whole mash is allowed to settle for two hours at 70° C., the top portion is first poured through a hot-water filter maintained at 70° C., and the entire residue is then washed on the same filter with water at about 80° C., until fully exhausted. The wort is weighed and the quantity of extract is determined from its specific gravity.

The results showed that the "two filtrates" method gives the same values as the "washing out" method which may be taken as correct, but that the "proportionality" method gives constantly higher numbers, the difference being about 1.7 per cent. The error involved in the "proportionality" method lies in the fixation of water by the chemical reaction of hydrolysis and in the

selective absorption of water by the solid residues of the rains.

With dark and steely malts, even in the case of a neutral, the full yield of extract is not obtained by the infusion method. In such cases, when a rigorous comparison between laboratory and brewery yields is required, the three-mash decoction principle should be followed in the laboratory. The increased yield so obtained by the theoretically correct "washing-out" or "two-filtrate" method is, however, never so high as to compensate the error inherent in the Berlin Congress standard method of determination.—J. F. B.

Esters in Spirits; Determination of — R. Duchenan and J. Dourlen. Bull. Assoc. Chim. Sucr. Dist., 1905, 23, 109–113.

The authors have investigated the errors caused by the oxidation of the alcohol in contact with the air during the operation of boiling with alkali for the saponification of the compound esters. Owing to the formation of acetic acid, and the consequent neutralisation of the alkali, these errors are liable to be very serious. It was found that the errors increased with the time of boiling, decreased with increased intensity of ebullition, owing to the exclusion of air from the condenser, increased with the proportion of aldehydes present in the spirit, these being more readily oxidised than the alcohol, and varied with the surface conditions of different flasks and condensers. The authors, therefore, propose to effect the saponification of the esters *in vacuo*, exhausting the flask containing the spirit and alkali by means of a mercury air pump. The evacuated flasks are immersed in a bath of boiling water, maintained at a constant level, the level of the water being below that of the spirit inside the flasks. It is shown that a period of one hour under these conditions is sufficient to complete the saponification of the esters, even when present in relatively large proportions, and that the results obtained are very satisfactory.—J. F. B.

Formaldehyde; Hydrogen Peroxide Method of Determining — J. K. Hayward and B. H. Smith. J. Amer. Chem. Soc., 1905, 27, 1183–1188.

The authors find that the Blank and Finkenbeiner method of determining formaldehyde (this J., 1899, 79, 614) occasionally gives incorrect results, probably owing to a secondary action of the formaldehyde on the 2N-caustic soda solution employed. By using N/1 caustic soda solution, and mixing it with the whole of the hydrogen peroxide before adding the formaldehyde, this source of error is avoided, but the time required is about 30–45 minutes at the ordinary temperature. At 100° C., however, only a few minutes are required, and the following method of working has been found to give safe, accurate results. Fifty c.c. of N/1 caustic soda solution are mixed in a flask with 50 c.c. of pure 3 per cent. hydrogen peroxide solution, and then 3 c.c. of the formaldehyde solution under examination (the sp. gr. of which has been previously determined) are added from a pipette, the point of which almost reaches the liquid in the flask. A funnel is placed in the neck of the flask, and the whole is heated on the steam-bath for five minutes, with occasional shaking. The funnel is then rinsed with distilled water, the flask cooled to the ordinary temperature, and the excess of sodium hydroxide titrated with N/1 acid, using litmus as indicator. See also this J., 1905, 693.)—A. S.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Fluorescent Screens; Regeneration of — Bordier. Arch. d'Elect. Med., Aug. 24, 1905. Electrician, 1905, 55, 859.

Screens of barium platinocyanide occasionally change colour from green to yellow and brown under the influence of prolonged exposure to X-rays, and, at the same time, lose their fluorescence. This change is due to loss of moisture owing to the ionising action of the X-rays; it can also be effected by desiccating the screens by gentle heat, or by absorbing the moisture with sulphuric acid. Screens prepared with a material which is readily permeated by

water can be regenerated by exposure to steam, but those prepared with collodion must be broken up and extracted with water, the barium platinocyanide being subsequently crystallised out from the solution.—A. S.

Gold-coated Teeth in Sheep; So-called "Laver-sidge" — Chem. News, 1905, 92, 115–116.

STATEMENTS have appeared recently that gold-coated teeth have been found in sheep. The teeth of the lower half of a sheep's jaw-bone, examined by the author, were more or less completely incrustated with a yellow metallic substance, more closely resembling iron pyrites (marcassite) or brass than gold. The incrustation was brittle, and readily came off in scales when even lightly scratched with the point of a penknife. The surface of the tooth under the scale was found to be black but apparently not decayed, for when the black coating was scraped off, the surface of the tooth was white. The thickness of the deposit did not apparently exceed the $\frac{1}{16}$ of an in. or less than 1 mm. Only one tooth was scaled.

The scale partly dissolved in dilute acid. The residue consisted of filmy organic matter, still possessing a metallic sheen, although white in colour instead of yellow. When heated on platinum foil the scale blackened, partly fused and left a white residue soluble in dilute hydrochloric and nitric acids.

The residue contained phosphoric acid, and apparently consisted mainly of calcium phosphate. Under the microscope, the scale appeared to be translucent, and of a pale brownish colour, and with a $\frac{1}{2}$ in. objective it was seen to be made of thin layers, but there was no recognisable organic structure. The metallic lustre is due to the way in which the light is reflected from the surfaces of the superimposed films; the incrustation on the teeth is apparently a deposit of tartar, and perhaps accompanied by slight superficial decay of the tooth.—T. F. B.

Trade Report.

II.—FUEL, GAS, AND LIGHT.

COAL INDUSTRY OF BRITISH INDIA IN 1904.

Bd. of Trade J., Sept. 21, 1905.

According to an official memorandum received through the India Office, the division of mining properties show considerable changes in Bengal, the number of mines in that province in 1904 being 61 fewer than in 1901, while there was an increase in 1904 of 17 mines in other provinces, mainly owing to small workings started in the Jhelum district of the Punjab. The total number of coal mines in operation in 1904 was 296 (256 in Bengal), compared with 302 (279 in Bengal) in 1903. The production in Bengal in 1904 represents more than six-sevenths of the whole Indian output of coal, which has been as follows in the last five years:—

	Tons.		Tons.
1900	6,118,692	1903	7,438,386
1901	6,635,727	1904	8,216,706
1902	7,424,402		

COAL PRODUCTION OF U.S.A. IN 1904.

Bd. of Trade J., Sept. 21, 1905.

According to the "Bulletin of the American Iron and Steel Association" the production of all kinds of coal in the United States in the calendar year 1904 amounted to 314,562,881 tons, against 319,068,229 tons in 1903, a decrease of 4,505,348 tons. Of the total production of last year 65,318,490 tons were Pennsylvania anthracite

and 249,244,391 tons were bituminous. In 1903 the production of Pennsylvania anthracite amounted to 66,613,454 tons and of bituminous coal to 252,454,775 tons. This was a decrease in 1904 as compared with 1903 of 1,294,964 tons of Pennsylvania anthracite and of 3,210,384 tons of bituminous.

The value of the anthracite produced decreased from 152,036,448 dols. in 1903 to 138,974,020 dols. in 1904, a loss of 13,062,428 dols., or 8.6 per cent., while the value of the bituminous produced declined from 351,687,933 dols. in 1903 to 305,842,268 dols. in 1904, a decrease of 45,845,665 dols., or 13.04 per cent. The average price per ton for the marketed sizes of anthracite coal in 1904 was 2.35 dols., as compared with 2.50 dols. in 1903, 2.35 dols. in 1902, and 2.95 dols. in 1901. The average price per ton of the bituminous coal produced in 1904 was 1.20 dol. compared with 1.24 dol. in 1903, 1.12 dol. in 1902, and 1.95 dol. in 1901.

There were 31 States and Territories in the United States in which coal was produced in 1904, an increase of one over 1903. A small amount of coal produced in Nevada last year adds that State to the list of producers.

NOTE.—The ton referred to is the ton of 2,240 lb.

COKE PRODUCTION OF U.S.A. IN 1904.

Bl. of Trade J. 8 pt. 21, 1905.

The "Bulletin" further reports that, including the production of coke from by-product ovens, which in 1904 amounted to 2,668,229 net tons, the total production of coke in the United States last year was 23,621,520 net tons, against 23,274,281 net tons in 1903. The decrease in 1904, as compared with the preceding year, was 1,652,761 net tons, or 6.54 per cent. The total value of the coke declined in much greater proportion, viz., from 66,498,664 dols. in 1903 to 46,026,183 dols. in 1904, a decrease of 20,472,481 dols., or 31 per cent. The average price for all the coke made and sold in 1904 was only 9 cents less than that in 1903, and was higher than that of any year from 1893 to 1899 inclusive. In 1903 the value of the coal used in the manufacture of coke was 42,447,449 dols., while in 1904 it was 37,133,832 dols. Of the total production of coke in 1904 Pennsylvania produced over 62 per cent., or 14,861,064 net tons out of a total of 23,621,520 tons.

NOTE.—Net ton = 2,000 lb.

III.—TAR PRODUCTS, PETROLEUM, Etc.

ASPHALTUM AND BITUMINOUS ROCK PRODUCTION IN 1904.

Eng. and Mining J., Sept. 9, 1905.

The production of asphaltum and bituminous rock in the United States during 1904, according to Dr. E. O. Hovey (Press Bul. 196, U.S. Surv.), amounted to 81,752 short tons (903,741 dols.), a decline of nearly 28 per cent. from that of 1903, which was 161,255 short tons (1,005,446 dols.). This decline is explained by the low price obtained and by the competition of the companies producing natural asphalt.

In reporting on asphaltum and bituminous rock, Dr. Hovey uses the term "asphaltum" to cover oil asphaltum as well as all the natural asphalt. The term "bituminous rock" covers the asphaltum-bearing sandstones and limestones which are quarried and used alone or mixed with other broken rock in the making of street pavements.

The output of bituminous sandstone decreased from 38,633 short tons (118,991 dols.) in 1903 to 19,641 short tons (71,465 dols.) in 1904. "Mastic" is given at 961 short tons (11,532 dols.) in 1903, most of which was produced from bituminous sandstone quarried in Kentucky; this increased to 1,200 short tons, valued at 10,800 dols. in 1904. The production of hard and refined or "gum asphalt" shows an increase in quantity from 12,896 short tons (343,799 dols.) in 1903 to 15,012 short tons (224,440 dols.) in 1904, though there was a decrease in value in 1904 of 119,353 dols. The production of liquid asphaltum,

or "maltha," was 3,360 short tons (36,260 dols.), reported from California, and three short tons (60 dols.) from Texas. The production of oil asphaltum decreased from 46,187 short tons (522,164 dols.) in 1903, to 36,030 short tons (376,135 dols.) in 1904; the average value per ton decreased from 11.31 dols. to 10.44 dols.

During the fiscal year ending June 30, 1904, asphaltum and manufactures of asphaltic material of domestic production to the total of 160,186 dols. were exported from the United States. The corresponding exports to the fiscal year ending June 30, 1903, amounted to 104,580 dols.

Nearly two-thirds of the asphaltum which is imported into the United States from foreign countries comes from Trinidad. Other important sources of the material are Venezuela (Burmudez), Cuba and France.

The imports from Trinidad decreased from 129,133 long tons (367,003 dols.) in the fiscal year ending June 30, 1903 to 110,031 long tons (368,623 dols.) in the fiscal year ending June 30, 1904; while the imports from Venezuela increased from 16,445 long tons in 1903 (74,874 dols.) to 50,194 long tons (217,017 dols.) in 1904. The imports from the British West Indies in 1904 include 649.5 short tons of manjak, valued at 28,578 dols. The total importation in 1904 were 175,640 long tons, valued at 643,785 dols. as compared with imports of 172,892 long tons, valued at 585,865 dols. in 1903.

IV.—COLOURING MATTERS, Etc.

ORCHIL AND ORCHIL EXTRACT: U.S. CUSTOMS DECISION. Aug. 18, 1905.

Orchil, invoiced as orchil R.C.E.P., is free of duty "orchil or orchil liquid" under paragraph 628 of the tariff the assessment of duty at 30 per cent. *ad valorem* as "colour" under paragraph 58 was overruled. Evidence was presented on the part of the importer that the merchandise was obtained from orchil lichens and not from orein derived from toluol or coal tar.—R. W. M.

V.—TEXTILES, YARNS, AND FIBRES.

GREASE; SOLUBLE — [ALIZARIN ASSISTANT]: U.S. CUSTOMS DECISION. July 17, 1905.

Following a decision of the Circuit Court, the Board General Appraisers decided that soluble grease made from tallow by sulphonation is dutiable at 20 per cent. *valorem* under section 6 as a "manufactured article unenumerated," and not under paragraph 32 as "alizarin assistant not specially provided for, i.e., not made from castor oil."—R. W. M.

VII.—ACIDS, ALKALIS, Etc.

BORAX: U.S. CUSTOMS DECISION. Aug. 31, 1905.

Merchandise invoiced as borate of soda, and consisting of 97.51 per cent. of crystallised borax and 2.59 per cent. of sodium carbonate, is held to be in fact "borax" and dutiable at 5 cents per lb. under paragraph 11 of the tariff.—R. W. M.

COPPER ACETATE: U.S. CUSTOMS DECISION. Aug. 15, 1905.

The Treasury Department has ordered the refund of duty on acetate of copper which had been assessed for duty 25 per cent. *ad valorem* as a "chemical salt," under paragraph 3 of the tariff. The Circuit Court decided that article was free of duty as "subacetate of copper" under paragraph 694.—R. W. M.

CHEMICAL AND OTHER INDUSTRIES OF LYONS IN 1904.

For. Off. Misc. Series, No. 638.

The accompanying table shows the consumption of pyrites for the production of sulphuric acid:—

	Quantity.		
	1902.	1903.	1904.
	Tons.	Tons.	Tons.
Production of mines, St. Bel ..	315,000	320,000	279,000
Exported	65,000	117,000	41,000
Consumption in France of St. Bel pyrites	250,000	203,000	228,000
Export of pyrites	171,000	205,000	195,000
Consumption	421,000	408,000	423,000

The above consumption of 423,000 tons of pyrites presents about 1,100,000 tons of sulphuric acid at $\frac{1}{2}$ B. The decline in the production of St. Bel was due to a strike; nevertheless the home sales were heavier than in 1903. Owing to the revival of the superphosphate industry the French industry in sulphuric acid seems to have regained the activity that marked it in 1902. The concentrated sulphuric acid industry remained much the same as in 1903.

The year 1904 was marked by a fall of 20 to 25 per cent. in the prices of mineral superphosphates, brought about by competition amongst producers. This fall caused an increase in the home consumption. The total consumption of superphosphates is estimated at 1,400,000 tons, which represents a consumption of 7,800,000 tons of sulphuric acid.

The fall in the prices of bone manure, coinciding with the decline in price of glues, placed the latter industry in a very unfavourable position, and caused the closing of several manufactories in France. Factories that do not exclusively produce low-quality glues maintained their activity by producing high-grade glues, which sold well.

The exports of French glue fell from 7940 tons in 1903 to 523 tons in 1904, the imports for the corresponding periods being 2428 and 2129 tons. The fall in imports could have partly compensated for the decrease in exports had there not been a considerable decline in the home consumption, owing to the depression of the trade. Production has fallen off, and several manufactories have been closed.

This reduction has been incidental with a falling-off in the production of leather trimmings throughout the French tan yards. The import of bones, another raw material, was also less, falling from 38,000 tons in 1903 to 3,000 tons in 1904. The export, on the other hand, which is principally to Belgium and Germany, increased from 6,500 to 9,000 tons.

No change was noticeable in the stearine and soap industry during 1904. The export increased from 43,813 quintals in 1903 to 49,251 quintals in 1904.

VIII.—GLASS, POTTERY AND EARTHENWARE.

GLASS EXPORTS OF BELGIUM.

For. Off. Ann. Series, No. 3501.

The exports of glass again showed a considerable falling-off in comparison with the year 1903, the decline amounting to 47,655 tons and 555,520*l.*, the figures for 1904 being 189,846 tons, valued at 3,022,600*l.* The decrease in the exports is largely due to the diminished quantity of glass of all kinds sent to the United Kingdom, the United States of America, Japan, Canada, Denmark and Egypt. The decrease in the exports to Japan was very marked, amounting to nearly two-thirds of the total exports to that country in 1903.

This dulness in the glass export trade is due to the smaller output of the factories owing to a general strike in the industry in the early part of 1904, and a consequent cessation of the glass supply. Orders have been placed more freely since the month of June in the present year (1905), and prices are keeping up to a fair standard, particularly in regard to special qualities of glass exported to Japan, China and Canada. The trade with the United Kingdom is not, however, very prosperous, and the lack of orders from that quarter has necessitated the lowering of prices for certain qualities of glass.

ELECTRITE; U.S. CUSTOMS DECISION.

Electrite, an earthy substance obtained by heating bauxite in the electric furnace and intended to be used after grinding as a substitute for emery, was held to be dutiable at 2 dols. per ton, under paragraph 93 of the tariff, as an "earth wrought or manufactured," and not at 20 per cent. *ad valorem*, as a "manufactured article unenumerated," under section 6, as assessed for duty.

—R. W. M.

IX.—BUILDING MATERIALS, Etc.

TIMBERS OF NEW SOUTH WALES.

Bull. Imp. Inst., 1905, 3, 119—124.

A description of the more important timbers exhibited in the New South Wales Court of the Imperial Institute is given, the timbers being grouped according to their suitability for special purposes.

Paving Timbers.—Tallow-wood (*Eucalyptus microcorys*, F. v. M.), blackbutt (*E. pilularis*, Sm.), red mahogany (*E. resinifera*, Sm.), forest red gum (*E. tereticornis*, Sm.), bloodwood (*E. corymbosa*, Sm.) and brush box (*Tristania conferta*, R.Br.). The red gum, spotted gum, and blue gum trees, which are species of *Eucalyptus*, and the "turpentine" tree are also used for paving purposes.

Timbers for Staves.—Silly-oaks (*Grevillea robusta*, A. Cunn. and *Orites excelsa*, R.Br.), red silly-oak (*Stenocarpus salignus*, R.Br.), mountain hickory (*Acacia penninervis*, Sieb.), blackwood (*Acacia melanoxylon*, R.Br.) and coachwood (*Ceratopetalum aptatum*, D. Don.).

White Ant-resisting Timbers.—Cypress pine (*Callitris* species), native teak (*Flindersia Bennettiana*, F. v. M.), red mahogany, brush box, red cedar (*Cedria australis*, F. v. M.), and "turpentine."

Teredo-resisting Timbers.—"Turpentine," tallow-wood, red mahogany, and ironbarks (*Eucalyptus* species).

Timbers suitable for railway wagons and sleepers, for carriage building, cabinet-making, veneers, gunstocks, turnery, and for panels, picture frames and walking sticks are also described.—A. S.

CEMENT EXPORTS OF BELGIUM.

For. Off. Ann. Series, No. 3501.

The exports of home-manufactured cement from Belgium declined from 599,091 tons in 1903 to 588,295 tons in 1904, the respective values for the two years being 623,040*l.* and 564,762*l.* The exports to the United Kingdom show an increase of 11.6 per cent. in volume, and of 2.6 per cent. in value, the figures for 1904 being 234,213 tons, of a value of 221,964*l.* While large amounts are sent to the United States of America, the Netherlands, Brazil, Argentine Republic and other countries, the amount exported to the United Kingdom far exceeds any of these, and comprises alone more than one-third of the total exports. The average prices for cement during 1904 continued to be very low and the profit to manufacturers was but small. The prices quoted for Belgian cement are still below those of Germany and the Netherlands, and it is, therefore, very probable that the exports of home-manufactured cement will show a satisfactory increase by the end of 1905.

During the first five months of 1905, 257,960 tons were exported, compared with 184,715 tons in the same period of 1904, forecasting a large increase for 1905.

CEMENT IN LYONS IN 1904.

For. Off. Misc. Series, No. 638.

The total annual production of cement of the Department of the Isère is about 180,000 tons. The Department of the Ain produces 100,000 tons; the Departments of Savoie and Haute Savoie conjointly about 30,000 tons. There is, besides, a small production in the Jura.

Argillaceous and calcareous strata are found in the neighbourhood of Grenoble. Fuel, which enters largely

*N.B.—The Australian turpentine tree, *Tristania Albicans*, is a species of myrtle.

into the cost of manufacture of cement, is provided by the anthracite mines of Lamure in close proximity to Grenoble, and a cheap and plentiful supply is always available. Rotary kilns, however, cannot be used, as the Lamure anthracite does not contain the necessary amount of ash, and produces abundant ash in combustion. Water-power is easily obtainable, and about 3,000 horse-power are now used for the manufacture of cement in the Department of the Isère. The amount of coal used is about 35,000 tons at 16s. per ton. The cost of labour is estimated at 60,000*fr.* per annum.

In 1885 the cement produced in the Grenoble district amounted to 175,000 tons of all qualities, representing a value of 320,000*fr.* and employing 1,250 hands.

To-day the cement industry is represented in the Department of the Isère by nine firms, employing 1,500 workmen, producing 180,000 tons, of which 135,000 tons are for home consumption and 45,000 tons or 25 per cent. for export via Belfort, Vallorbes, Geneva, Modane and Marseilles. The sale price at works varies from 12s. to 1*l.* 16s. per ton.

Whereas the price of fuel used in the manufacture of cement has increased of late years, and labour has become dearer, the sale prices of Grenoble cement tend to decrease. This has been brought about (1) by the excessive cost of transport in a district where the absence of canals gives a monopoly to the railways; (2) because cement works have been started in many other parts of France; and (3) because exports are daily decreasing. There are now cement factories in Algeria, Tunis, and Egypt, and excessive customs rates in Italy and Switzerland have killed the trade.

X.—METALLURGY.

IRON MINES IN TUNIS.

For. Off. Ann. Series, No. 3492.

The following particulars with reference to five important iron mines discovered in the north-west of Tunisia within recent years, are extracted from the report of H.M. Consul-General at Tunis:—

The concession for the working of the Djebel Zerissa mine was granted in 1901. This iron mine is situated at a distance of about 122 miles from the port of Tunis and about three-quarters of a mile from the railway running from Tunis to Kalâ-es-Senam, which will probably be opened to traffic during the latter part of this year. It is calculated at present that some 4,000,000 tons are available, and it is reported that there is a likelihood that this amount may be doubled when the mine is in full working order. The assays have shown this mineral to contain from 50 to 60 per cent. of iron and $\frac{1}{2}$ to 2 per cent. of manganese.

The concession for the Djebel Slatâ mine, which lies in the Kef district (to the north-west of Tunis), has been applied for by a Brussels syndicate. It is situated 131 miles from the Port of Tunis and about half a mile from the railway line running from Tunis to Kalâ-es-Senam. From recent researches which have been made in this mine it has been found that about 3,000,000 tons of ore are available. The analysis of the extracts is reported to be as follows:—55.77 per cent. of iron, 2.25 per cent. of manganese.

The concession for the Djebel Hammeima mine, which lies in the Kef district, has recently been applied for by the same syndicate. It is situated about 137 miles from the port of Tunis and about two and a half miles from the line running between Tunis and Kalâ-es-Senam. It is reported that some 6,000,000 tons of the mineral are available. From 70 assays the following result has been obtained:—59.53 per cent. of iron, 2.05 per cent. of manganese.

The Nabour mine is situated 112 miles from the port of Tunis and about 19 miles from the railway station of Souk-el-Arba (about 100 miles from Tunis) and lies at the feet of the Kef mountains. From several assays it has been found that it contains 48 to 53 per cent. of iron, and 2 to 4 per cent. of manganese.

The Djebel-Hallouf mine, which is said to extend for

about three-quarters of a mile, is situated 122 miles from the port of Tunis. The extracts are reported to contain 53.29 per cent. of iron and 0.90 per cent. of manganese.

In conclusion, Mr. Berkeley says, "It is asserted the between phosphates and these new iron mining developments something like 30,000,000 tons of extracts will be available for shipment within the near future."

ORE EXPORTS OF NEW CALEDONIA.

Bl. de T. adv. J., Sept. 21, 1905.

The "Quinzaine Coloniale" gives the exports of ore from New Caledonia during the first half of 1904 as follows:

	1904.	First half of 1905
	Kilos.	Kilos.
Nickel ore	98,655,104	65,172,164
Cobalt ore	8,964,183	5,283,222
Chrome ore	42,197,477	26,942,109

ALLOY; U.S. CUSTOMS DECISION. June 26, 1905.

The United States Circuit Court held that an alloy composed of 62 per cent. of iron, 32 per cent. of tin, and 6 per cent. of manganese, used as hardener in the manufacture of manganese bronze, is dutiable at 20 per cent. *ad valorem*, as a "metal unwrought" under paragraph 183 of the tariff, and not at 45 per cent. *ad valorem* as a "manufacture of metal" under paragraph 193.—R. W. M.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

KRYPTOL; U.S. CUSTOMS DECISION. July 19, 1905

Kryptol, a resistance material consisting of practically pure carbon, was held to be dutiable at 35 per cent. *ad valorem*, under paragraph 97 of the tariff, as an "article composed of carbon."—R. W. M.

XII.—FATTY OILS, FATS, Etc.

SOAP; U.S. CUSTOMS DECISION. July 27, 1905.

An analysis of the merchandise showed water, 62.89 per cent.; fatty acids, 28.81 per cent.; alkali as sodium carbonate, 7.49 per cent.; insoluble matter, 0.81 per cent. and the article was assessed for duty as "soap" under paragraph 72. The importer claimed it was free of duty as "soap stock" under paragraph 568. The Board of General Appraisers affirmed the assessment of duty and overruled the claim of the importer.—R. W. M.

OIL DISTILLED FROM WOOL GREASE ["WOOL OIL"] U.S. CUSTOMS DECISION. June 23, 1905.

An oil distilled from yellow grease and variously invoiced as wool oil, pure oleine, and pure oleine grease is dutiable at 25 per cent. *ad valorem* under paragraph of the tariff as an "expressed or rendered oil." The analysis of the sample showed:—Specific gravity at 15° 0.9085; free fatty acids, 53.90 per cent.; neutral fat 1.32; unsaponifiable matter, 44.78 per cent. The testimony showed that it was distilled from grease recovered from the suds resulting from wool scouring. The claim of the importer that it was dutiable as "wool grease" at $\frac{1}{2}$ cent. per lb. under paragraph 279 was overruled on the ground that it was no longer wool grease but a product obtained from wool grease.—R. W. M.

XIII.—PIGMENTS, PAINTS, Etc.

COLOURS FOR GLASS AND CHINA CONTAINING LEAD U.S. CUSTOMS DECISION. Aug. 30, 1905.

Colours used to colour glass and china containing lead are dutiable at five cents per lb. under paragraph 54

colours containing lead." The assessment of duty at per cent. *ad valorem* as "colours" was overruled.

—R. W. M.

UNT MIXED WITH VARNISH. U.S. CUSTOMS DECISION. July 17, 1905.

Following a decision of the Circuit Court, the Board of General Appraisers held that enamel white, consisting of fat ground in varnish, is dutiable at $1\frac{1}{2}$ cents per lb. under paragraph 57 of the tariff act, and not as "varnish" 35 per cent. *ad valorem*, nor as "paint" at 30 per cent. *ad valorem*. The Department has ordered an appeal on this decision if representative samples of the merchandise have been retained.—R. W. M.

OIL AND PAINT IMPORTS OF CAPE COLONY.

Chem. and Drug., Sept. 23, 1905.

Owing to the increasing importations of adulterated white and red lead, white zinc, linseed oil, and turpentine to Cape Colony, representations have been made to the Cape Government with the object of making illegal such seneous trade descriptions. Instructions have now been issued stating that all importations of white-lead, white-zinc, red-lead, and similar compositions, linseed oil, and turpentine shall only be passed by the customs authorities when marked "reduced," "mixed," "boiled," "mineral," but that if adulterated to the extent of 50 per cent. or more the actual percentage of such adulteration must also be conspicuously marked.

XIIC.—INDIA-RUBBER.

RUBBER INDUSTRY OF FEDERATED MALAY STATES.

Bd. of Trade J., Sept. 28, 1905.

The Report on Experimental Plantations in the Federated Malay States in 1904 states that agricultural interest in these States is almost entirely centred in the cultivation of the "Para" rubber tree. This cultivation has now got well beyond the experimental stage, and there is no longer any doubt as to whether the tree is suited to the conditions obtaining in the Federated Malay States, or whether its cultivation will prove remunerative. Tapping on a commercial scale has commenced on several estates, and exports for the year ending Dec. 31 last amounting to 105 pikuls (about 14,000 lb.) valued at over 28,000 dollars. It, as the oldest estates are just coming into bearing, its amount will be greatly exceeded in the near future, and prices realised have exceeded the most sanguine expectations, having averaged almost 1s. per lb. more than fine Para," the price of which has advanced nearly 10 per cent. during the last 12 months. The fact that "plantation Para" advanced 1s. 6d. per lb. during the year 1904, as against a rise of 1s. 2d. per lb. for "fine Para" would seem to show that, in the opinion of the manufacturer, the value of "plantation Para" increases on acquaintance. The Report adds:—"There is little doubt, if the quality is kept up to the present high level, that if the supply of high-grade rubber ever exceeds the demand, the cultivated product will be the last to suffer: moreover, it seems more than probable that, owing to its quality, the facility and comparatively low cost at which it can be harvested, 'plantation Para' will eventually displace the native product from the markets of the world."

XIV.—TANNING, LEATHER, GLUE, Etc.

UTGALLS; EXTRACT OF —. U.S. CUSTOMS DECISION. June 14, 1905.

The United States Circuit Court decided that aqueous extract of nutgalls is dutiable at $\frac{1}{4}$ cent per lb. and 10 per cent. *ad valorem*, under paragraph 20 of the present tariff, as "drugs such as nutgalls advanced in value or condition." This decision reverses a decision of the Board of General Appraisers, which held the merchandise to be dutiable as "tannin," at 50 cents per lb., under paragraph 1, and sustains a former decision of the Board. The Court also found that the extract was not com-

mercially known as tannin or tannic acid, and not dutiable as such nor as a "chemical compound," since the only chemical added was a preservative and maintained rather than changed the character of the extract. It is understood that this decision will be appealed, on the part of the Government, to the Circuit Court of Appeals.—R. W. M.

LEATHER IN LYONS IN 1904

For. Off. Misc. Series, No. 638

The Department of the Rhone is advantageously placed as regards leather, and raw material is easily obtained. Oxen, cows, calves and sheep slaughtered at Lyons provide skins of good quality. The Dauphiny and Italy furnish kid and lamb-skins, Algeria, Tunis and Morocco contribute goat-skins through Marseilles.

The quantity of hides and skins treated are: (1) 100,000 ox and cow hides, valued raw at 140,000*fr.*, and representing between 200,000*fr.* and 210,000*fr.* finished; (2) 500,000 to 600,000 calf-skins of a value of 200,000*fr.* to 240,000*fr.*, raw and of 240,000*fr.* to 320,000*fr.* finished; (3) 1,500,000 goat-skins of an estimated value of about 200,000*fr.*, raw and about 280,000*fr.* in the finished state; (4) 300,000 sheep-skins, valued at 28,000*fr.* to 32,000*fr.*, raw and 40,000*fr.* finished.

The total production of leather at Lyons is estimated at about 850,000*fr.* The immediate neighbourhood consumes about one-third of the total output, one-third is consumed in other parts of France and the remaining third is exported.

For the last 10 years, however, the hide and skin trade has not been flourishing. The dressed calf and kid-skins, which formed the speciality of the Lyons industry, were rejected by buyers, who preferred chrome-tanned skins. The introduction of chrome tanning was somewhat slow, and this revolution in the industry caused many failures among the less prosperous factories. At the present time, however, the French tanning industry is well equipped and capable of holding its own against foreign competition. Three years ago the "Ecole française de tannerie" was started in Lyons, with excellent results, and now supplies the scientific branch of the leather industry with capable experts.

XVI.—SUGAR, STARCH, Etc.

SUGAR PRODUCTION OF GERMANY.

Bd. of Trade J., Sept. 21, 1905.

The "Reichsanzeiger" for 13th September publishes statistics of the production of sugar in Germany during the campaign 1904-5 (from Sept. 1st, 1904, to Aug. 31st, 1905). In 1904-5 the quantity of raw beet used in sugar manufacture was 10,080,538 metric tons as compared with 12,677,099 metric tons during the 1903-4 campaign; the amount of raw sugar produced in 1904-5 was 1,362,732 metric tons against 1,665,352 metric tons in 1903-4, whilst the production of refined sugar amounted to 1,298,515 metric tons in 1904-5 as compared with 1,410,553 metric tons in 1903-4. The total output of sugar (raw and refined) during the period 1904-5, expressed in terms of raw sugar, was 1,615,189 metric tons as compared with 1,929,415 metric tons in 1903-4.

SUGAR PRODUCTION OF ITALY.

For. Off. Ann. Series, No. 3496.

As was anticipated in a former report, the production of sugar in Italy has continued to increase largely, resulting in a considerable loss to the customs on the duties on imported sugar. There are now 34 factories in Italy for the production of the article, of which the most important produces 61,309 quintals annually. The total output of Italy for the year 1903-04 is 1,308,606 quintals, or 354,515 quintals* more than in 1902-03. The supply is, in fact, greater than the demand, and there are considerable stocks standing over.

* Quatal=110.2 lb.

The duty on the home-grown sugar produced 64,115,000 lire in 1902-03 in contrast to 52,558,000 lire in 1903-04, a loss to the revenue of 11,557,000 lire (462,280%).

This loss, however, is due in part to the new methods of collection of the duty. Formerly the duties were paid at fixed and frequent periods, now they are collected when the sugar is sent out for consumption. For example, on the old system the whole tax on the sugar produced (1,308,606 quintals) that is to say, 88,973,246 lire, would have been levied and would have figured to the credit of the revenue, but by the new system as only 782,107 quintals were issued to consumers, the tax received amounted only to 52,558,000 lire.

The importation of foreign sugar is reduced to a negligible quantity, and has been falling steadily for the last four years. Thus we have:—

Year.	Quantity.
	Quintals.
1910	552,559
1911	371,895
1912	200,095
1913	52,678
1914	4,599

XVII.—BREWING, WINES, SPIRITS, Etc.

ALCOHOL TAX: FRENCH — : U.S. TREASURY DECISION.

Aug. 25, 1905.

The Treasury Department has ordered the refund of the excess of duties exacted on certain brandy and preserved fruits containing alcohol, in which the French revenue taxes known as "Octroi" and "droit de ville" had been included in the market value on appraisal. This addition had been declared unwarranted by the United States Circuit Court of Appeals.—R. W. M.

BREWERIES OF BRITISH INDIA.

Bd. of Trade J., Sept. 28, 1905.

According to a memorandum received at the Board of Trade through the India Office, the quantity of beer brewed in India in 1904 amounted to 6,219,761 galls., of which 46 per cent. was bought by the Army Commissariat. There are 27 breweries, of which one at Delhi was idle, 21 are private property. The quantity of beer brewed in India and imported compare as follows, in galls.:—

Year.	Brewed in India.	Year ended 31st March.	Imported.
1900	4,947,841	1900-01	3,226,534
1901	5,554,453	1901-02	3,673,852
1902	6,474,860	1902-03	3,820,938
1903	6,067,041	1903-04	4,062,016
1904	6,219,761	1904-05	4,606,827

XX.—FINE CHEMICALS, Etc.

OIL OF GARDENIA: U.S. CUSTOMS DECISION.

June 26, 1905.

Oil of gardenia, containing 27.7 per cent. of alcohol, was held to be dutiable at 60 cents per lb., and 45 per cent. *ad valorem*, as an "alcoholic compound," under paragraph 2 of the tariff.—R. W. M.

CHEYSAROBIN: U.S. CUSTOMS DECISION.

The Treasury Department has decided not to appeal from a decision of the United States Circuit Court which held chrysarobin to be dutiable under paragraph 20 of the

tariff, at $\frac{1}{2}$ cent per lb., and 10 per cent. *ad valorem*, as "drug advanced in value or condition by refining," &c. The contention of the Government that it was dutiable at 25 per cent. *ad valorem*, under paragraph 68, as a "medicinal preparation," was not sustained.—R. W. M.

ACETIC ANHYDRIDE: U.S. CUSTOMS DECISION.

June 28, 1905.

The Treasury Department has decided not to contest the decision of the Circuit Court which held acetic anhydride to be dutiable as "acetic acid" under paragraph 1 of the present tariff at 2 cents per lb. The claim of the Government that it was dutiable at 25 per cent. *ad valorem* under paragraph 3 as a "chemical compound" was not sustained.—R. W. M.

CHLORIDES OF PLATINUM, IRIUM AND RHODIUM: U.S. CUSTOMS DECISION Aug. 25, 1905.

The above-mentioned salts were held to be dutiable at 25 per cent. *ad valorem* as "chemical salts" under paragraph 3 of the tariff. The Board held that they were not free of duty as "minerals crude" under paragraph 61 or as "mineral salts obtained by the evaporation of water from a mineral spring," under paragraph 615.—R. W. M.

MUSK: ARTIFICIAL — : U.S. CUSTOMS DECISION

Sept. 5, 1905.

Artificial musk, or trinitro-isobutylxylool, which results from the interaction of 106 parts of xylool, 74 parts isobutyl alcohol and 189 parts of nitric acid, is not "preparation or product of coal tar," dutiable at 20 per cent. *ad valorem* under paragraph 15 of the tariff, but "chemical compound" dutiable at 25 per cent. under paragraph 3.—R. W. M.

Patent List.

N.B.—In these lists, [A.] means "Application for Patent," and [C.S.] "Complete Specification Accepted."

Where a Complete Specification accompanies an Application, asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journal in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open inspection at the Patent Office immediately, and to opposition within two months of the said dates.

JOURNAL OF THE Society of Chemical Industry.

A RECORD

FOR ALL INTERESTED IN CHEMICAL AND ALLIED MANUFACTURES.

ISSUED TWICE A MONTH.

No. 20.—Vol. XXIV.

OCTOBER 31, 1905.

No. 20.—Vol. XXIV.

Subscription of Members 25 - per annum;
Entrance Fee 21/-;
Election by the Council.

Price to Non-Members 36 - per annum;
To Members 25 - per Set of extra or back numbers.
Single copies (Members and Subscribers only).
1882—1901, 2 6 each; 1902 *et seq.*, 1 9 each.

The Society of Chemical Industry.

Past Presidents:

Sir Henry E. Roscoe, B.A., D.C.L., LL.D., Ph.D., F.R.S.	1881—1882.
†Sir Frederick A. Abel, Bart., K.C.B., G.C.V.O., D.C.L., D.Sc., F.R.S.	1882—1883.
†Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, LL.D., Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Sir James Dewar, M.A., LL.D., F.R.S.	1887—1888.
Ludwig Mond, Ph.D., F.R.S.	1888—1889.
†Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
†E. Rider Cook	1890—1891.
J. Emerson Reynolds, M.D., F.R.S.	1891—1892.
Sir John Evans, K.C.B., D.C.L., LL.D., Sc.D., F.R.S.	1892—1893.
†E. C. C. Stanford	1893—1894.
T. E. Thorpe, C.B., LL.D., Sc.D., Ph.D., F.R.S.	1894—1895.
Thomas Tyrer	1895—1896.
†Edward Schunck, Ph.D., F.R.S.	1896—1897.
Frank Clowes, D.Sc.	1897—1898.
George Beilby	1898—1899.
C. F. Chaudier, D.Sc., M.D., Ph.D., LL.D.	1899—1900.
Sir Jos. W. Swan, D.Sc., M.A., F.R.S.	1900—1901.
Ivan Levinstein	1901—1903.
Sir W. Ramsay, K.C.B., D.Sc., LL.D., F.R.S.	1903—1904.
Wm. H. Nichols, M.Sc., LL.D., D.Sc.	1904—1905.

† Deceased.

LIST OF COUNCIL, 1905—1906.

President: Dr. Edw. Divers, F.R.S.

Vice-Presidents:

Dr. L. Baekeland.	Dr. J. Lewkowitsch.
J. Carter Bell.	N. H. Martin.
Dr. Virgil Coblentz.	Max Muspratt.
Prof. W. R. E. Hodgkinson.	Dr. Wm. H. Nichols.
David Howard.	T. J. Parker.
Ivan Levinstein.	Sir Wm. Ramsay, K.C.B., F.R.S.

Ordinary Members of Council:

Dr. J. T. Dunn.	Dr. K. E. Markel.
Oscar Guttmao.	B. E. R. Newlands.
H. Hemingway.	Prof. W. J. Pope, F.R.S.
Prof. W. R. Lang.	Sir Boverton Redwood.
A. R. Ling.	Walter F. Reid.
J. S. McArthur.	Dr. W. S. Squire.

Sectional Chairmen and Secretaries:

BIRMINGHAM.	F. R. O'Shaughnessy.
Prof. Percy F. Frankland, F.R.S.	CANADIAN.
Dr. F. J. Smale.	Alfred Burton.
Estace Carey.	LIVERPOOL.
A. Gordon Salamoun.	W. Roscoe Hardwick.
Dr. G. H. Bailey.	LONDON.
Prof. H. Louis.	Julian L. Baker.
Henry Howard.	MANCHESTER.
Dr. Russell W. Moore.	Julius Hübner.
J. M. C. Paton.	NEWCASTLE.
David Perry.	Dr. F. C. Garrett.
Prof. A. Liversidge, F.R.S.	NEW ENGLAND.
Prof. H. R. Procter.	Alan A. Claffin.
	NEW YORK.
	Dr. H. Schweitzer.
	NOTTINGHAM.
	S. R. Trotman.
	SCOTTISH.
	Dr. Thos. Gray.
	SYDNEY, N.S.W.
	T. E. Walton.
	YORKSHIRE.
	Thos. Fairley.

Honorary Treasurer:

Samuel Hall, East London Soap Works, Bow, E.

Hon. Foreign Secretary:

Dr. Ludwig Mond, F.R.S.

General Secretary:

Charles G. Cresswell, 59, Palace Chambers, Westminster, S.W.

Birmingham Section.

Chairman: Percy F. Frankland.

Vice-Chairmen:

W. Waters Butler, Frank E. Lott,* Alex. E. Tucker.

Committee:

Robt. B. Batty.	Edward Jackson.	T. Slater Price.
Wm. B. Davidson.	Thos. Lawton.	Walter Rosenhain.
Alex. Findlay.	Alex. McKenzie.	Harry Silvester.
Henry L. Heathcote.	Frank Platten.	Thos. Turner.

Hon. Local Secretary and Treasurer:

F. R. O'Shaughnessy, Tyburn, nr. Birmingham.

Canadian Section.

Chairman: F. J. Smale.

Vice-Chairmen:

W. H. Ellis, A. McGill, B. J. Harrington.

Committee:

J. H. Bowman.	Chas. H. Heyes.	M. J. Taylor.
Jeffrey H. Burland.	W. R. Lang.	Harold Vander Linde.
Thos. Davies.	W. Lash Miller.	W. H. Van Winckel.
Milton L. Hersey.	Jas. P. Murray.	

Hon. Treasurer: J. W. Bain.

Hon. Local Secretary:

Alfred Burton, 44, York Street, Toronto.

Liverpool Section.

Chairman: Eustace Carey.

Vice-Chairman: Frank Tate.

Committee:

T. Lewis Bailey.	J. T. Conroy.	C. Longuet Higgins.
J. Campbell Brown.	H. E. Davies.	E. L. Peck.
Arthur Carey.	A. Foden.	W. Collingwood.
G. C. Clayton.	G. Watson Gray.	Williams.

Hon. Treasurer: W. P. Thompson.

Hon. Local Secretary:

W. R. Hardwick, 13, Batavia Buildings, Hackins Hey, Liverpool.

London Section.

Chairman: A. Gordon Salamon.

Vice-Chairman: R. J. Friiswell.

Committee:

E. J. Bevan.	D. L. Howard.	Boverton Redwood.
H. G. Colman.	G. C. Jones.	Walter F. Reid.
J. N. Connah.	A. R. Ling.	F. Napier Sutton.
M. O. Forster.	B. E. R. Newlands.	Chas. Wightman.
Oscar Guttman.	Wm. Pearce.	

Hon. Local Secretary:

Julian L. Baker, Stainesbury Holt, Kingston Road, Staines.

Manchester Section.

Chairman: G. H. Bailey.

Vice-Chairman: F. Scudder.

Committee:

J. Barnes.	B. Hart.	J. H. Lester.
J. Bürger.	W. B. Hart.	H. Porter.
W. H. Coleman.	R. S. Hutton.	T. Stenhouse.
J. Grossmann.	W. E. Kay.	W. Thomson.

Hon. Local Secretary:

Julius Hübner, Ash Villa, Cheadle Hulme, Cheshire.

Newcastle Section.

Chairman: H. Louis.

Vice-Chairman: J. T. Dunn.

Committee:

P. P. Bedson.	John Pattinson.	Harry Smith.
H. S. Collins.	W. W. Proctor.	A. Spiller.
Ellwood Holmes.	W. L. Renuoldson.	J. E. Stead.
N. H. Martin.	Geo. Sisson.	C. E. Stuart.

Hon. Local Secretary and Treasurer:

F. C. Garrett, Armstrong College, Newcastle-on-Tyne.

New England Section.

Chairman: Henry Howard.

Vice-Chairman: F. E. Atteaux.

Committee:

C. R. Borland.	L. A. Olney.	Charles R. Sange.
W. A. Gallup.	Edw. D. Pearce.	F. H. Thorp.
A. F. Hobbs.	A. Reuter Dahl.	W. H. Walker.

Official Notices.

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

SIXTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY, ROME, 1906.

The Sixth International Congress of Applied Chemistry will be held in Rome in April, 1906, during Easter week. All communications should be addressed to the President, Prof. E. Paternò, Via Panisperna, 89 Rome.

List of Members Elected.

October 23rd, 1905.

Barraclough, C. E., Wood View, Manningham, Bradford, Chemist.
 Beckers, Dr. Wm., 40, Stone Street, New York City, U.S.A., Chemist.
 Bone, Dr. W. A., F.R.S., Rokeby House, Enwood Road, Levenshulme, Manchester, Lecturer in Chemistry and Metallurgy.
 Crabbrook, Geo. Hale, Taunton, Mass., U.S.A., Manufacturer.
 Brettell-Vanhan, E., S. St. Ann's Road, Wandsworth, S.W., Storage Battery Analyst.
 Bristol, H. Stanley, 74, Pinekney Street, Boston, Mass., U.S.A., Chemist.
 Campbell, Wm. A., 309, 14th Street, Milwaukee, Wis., U.S.A., Chemist, Wadhams Oil Co.
 Carleton, Philip H., Wamesit Station, Tewksbury, Mass., U.S.A., Selling Agent.
 Clark, Alfred N., Box 168, Wallaceburg, Ont., Canada, Technical Chemist and Engineer.
 Crosskey, A. N., Mundesley Sanatorium, Norfolk, Analytical Chemist.
 Culver, Ralph F., 53, Meadow Street, Pawtucket, R.I., U.S.A., Chemist.
 Cumming, R. Burns, Currie Street, Adelaide, S. Australia, Manufacturing Chemist.
 Dearman, E., "Highcliffe," Gladstone Avenue, Woolwich, N.S.W., Australia, Tar Distiller.
 Duché, E., 6, Eastcheap, London, E.C., Merchant.
 Easton, Herbert Fyfe, Herodsfoot, St. Keyne, R.S.O., Cornwall, Manager of Explosives Factory.
 Emmett, Jas. R., 36, Purchase Street, Boston, Mass., U.S.A., Chemist.
 Fynon, Lewis, 57, Darent Road, Stamford Hill, N., Chief Chemist, London Beetroot Sugar Association.
 Ish, Chas. H., Coheco Manufacturing Co., Dover, N.H., U.S.A., Textile Manufacturer.
 Lance, Edward W., Philadelphia Textile School, Broad and Pine Streets, Philadelphia, Pa., U.S.A., Director.
 Ordner, Franc E., 633, North Western Avenue, Chicago, Ill., U.S.A., President Gardner-Barada Chemical Co.

George, J. K., 145, La Salle Street, Chicago, Ill., U.S.A., Manufacturer.
 Gorsline, William H., Rochester Sewer Pipe Co., Rochester, N.Y., U.S.A., Secretary and Manager.
 Hartshorne, Wm. D., 40, Pleasant Street, Methuen, Mass., U.S.A., Agent (Arlington Mills).
 Hartwell, F. O., c/o Holyoke Card and Paper Co., Springfield, Mass., U.S.A., Purchasing Agent.
 Heberlein, Dr. Edward, c/o H. T. Enthoven and Sons, Ltd., 247, Rotherhithe Street, London, S.E., Works Manager.
 Hough, Warwick M., 902, Rialto Building, St. Louis, Mo., U.S.A., Attorney-at-Law.
 Johnstone, John Swanston, National Distilleries Co., Bond Street, Durban, Natal, Distiller.
 Joseph, A. F., 95, Marylands Road, Maida Vale, London, W., Lecturer in Chemistry.
 King, Alex. E., 18, The Common, Woolwich, S.E., Lieut. R.A.
 Laycock, Thomas P., The Hawthorns, London Road, Peterborough, Manager of Wrigleys, Ltd.
 Lévy, René J., c/o Société L'Air Liquide, 62, Rue Saint Lazare, Paris, France, Chemist and Technical Manager.
 McCaw, Major Walter D., Library, Surgeon General's Office, Washington, D.C., U.S.A., Officer, Medical Department, U.S. Army.
 Metzis, Josef, Anglicia Petroleum Co., Drohobycz, Galicia, Austria, Manager of Refinery.
 Neymann, Dr. Percy L., Republican House, Milwaukee, Wis., U.S.A.
 Norden, Julius, United Chemical Works, 94, Leadenhall Street, E.C., Chemical Manufacturer.
 Potter, N. S., jun., c/o Western States Portland Cement Co., Independence, Kas., U.S.A., Chemist.
 Prentiss, George L., c/o Parson Manufacturing Co., 299, Broadway, New York City, U.S.A., Treasurer.
 Ridge, H. M., c/o Inst. of Mining and Metallurgy, Salisbury House, London Wall, E.C.; and (Journals), c/o 13, King Edward's Mansions, Shaftesbury Avenue, W.C., Mining Engineer.
 Ryland, Chawner, 53, Park Road, Aston, Birmingham, Brewer and Chemist.
 Schweizer, Alfred, 14, Rue de Calais, Paris, France.
 Seeker, Albert F., 528, Eighth Street, Brooklyn, N.Y., U.S.A., Food Analyst.
 Stanley, Harry, 3, St. Michael's Park, Bristol, Lecturer in Applied Physics and Engineering.
 Steiger, George, U.S. Geological Survey, Washington, D.C., U.S.A., Chemist.
 Tolson, Stanley, c/o The Dunlop Rubber Co., Ltd., Manor Mills, Aston, Birmingham, Chemist.
 Van Linge, Dr. A. R., Maarssen, Holland, Manufacturing Chemist.
 Watson, James, 41, Sherburn Street, Holderness Road, Hull, Works Chemist.
 Webber, W. J., 55, Kilby Street, Boston, Mass., U.S.A., Manufacturing Chemist.
 Weber, Nicholas M., 71, Mail Street, West Lynn, Mass., U.S.A., Leather Manufacturer.
 White, William, Beloeil Station, Province Quebec, Canada, Chemist.
 Whitehead, Walter, 82, Ship Avenue, Medford, Mass., U.S.A., Manufacturer of Textile Chemicals.
 Wilson, J. E., c/o General Chemical Co., 25, Broad Street, New York City, U.S.A., Chemical Salesman.
 Wright, Daniel, 287, Maverick Street, East Boston, Mass., U.S.A., Manufacturer of Dyestuffs and Chemicals.
 Zimmermann, Chas., 9 and 10, St. Mary-at-Hill, London, E.C., Chemical Merchant.

Changes of Address.

When notifying new addresses, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is also to be avoided as tending to create confusion. When sending subscriptions, the use of the form attached to the application helps in the verification of addresses, on which the safe delivery of the Journal depends.

Bradbury, S., 1/o Castleton; Ferncliffe, Milton Grove, Glebelands Road, Ashton-on-Mersey.
 Bryant, V. Seymour, 1/o Camborne; 80, Beeches Road, West Bromwich.
 Cheke, Thos. W., 1/o Stroud Green; 43, Hockerill Street, Bishop's Stortford, Essex.
 Conroy, Dr. Jas. T., 1/o Howard Drive; Adirondack, Grassendale Park, Liverpool.
 Crowther, J., 1/o Adelaide; retain Journals.
 De Cew, J. A., 1/o Quebec; 14, Sun Life Building, Montreal, Canada.
 Doolittle, O. S., 1/o Reading; c/o Somet-Solvay Co., 17, Battery Place, New York City, U.S.A.
 Ewing, Dr. A. R., 1/o Lennoxton; 8, Glasgow Street, Hillhead, Glasgow.
 Feilmann, Dr. E., 1/o Derby; c/o Jno. Feilmann and Co., Ltd., 12, Short Hill, Nottingham.
 Fernberger, H. M., 1/o Niagara Falls; Dollar Bay, Houghton Co., Mich., U.S.A.
 Graham, C. C., 1/o Ilkley; Oriel House, Scarborough.
 Gross, H. B.; Journals to 18, Hyde Park Place, London, W.
 Hall, Max M., 1/o Gloucester Street; Laby., 188, Metcalf Street, Ottawa, Ont., Canada.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—8d. each, to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, E.C.

United States.—1s. each, to the Secretary of the Society.

French.—1 fr. 25 c. each, to Belin et Cie, 56, Rue des Francs-Bourgeois, Paris (3^e).

I.—PLANT, APPARATUS, AND MACHINERY.

Vacua; Dewar's Method of Producing High ——. Lord Blythwood and H. S. Allen. Phil. Mag., 1905, 10, 497—512.

DEWAR'S method for producing high vacua, depending on the absorption of gases by charcoal at low temperatures (see this J., 1905, 793), can be applied to the exhaustion of large receivers, it being only necessary to increase the size (or number) of the charcoal receptacles. Only moderate amounts of liquid air are necessary for the method. The volume of air absorbed by charcoal (at the temperature of liquid air) is, "to a first approximation," independent of the quantity originally present in the apparatus. The rate of absorption was found to be practically independent of the pressure, and to stand in a constant ratio to the amount of air which the charcoal is still capable of absorbing.—T. F. B.

ENGLISH PATENTS.

Volatile Liquids; Apparatus for Separating and Condensing the Vapours of ——. H. Heymann, Bradford; and H. Hey, J. Smith, H. L. Mitchell, and W. H. Askham, Dowsbury. Eng. Pat. 17,435, Aug. 10, 1904.

FIG. 1.

FIG. 2.

IMPROVEMENTS are claimed for condensers and separators or use in connection with the vapours of volatile liquids or solvents used in the cleaning of woollen cloth and other goods in india-rubber waterproofing, &c. One form of the condensing and separating apparatus consists of a cylinder *a* (see fig.), terminating in two funnels *m* and *n*,

and containing baffle-plates *c* and a vertical sheet of wire gauze *d*, the latter of which projects into a cooling jacket *b* surrounding the cylinder. The vapour to be condensed is forced through a pipe *g* into a vessel *p* filled with oil. The unabsorbed vapour passes thence, with or without oil from the vessel *p*, through the cylinder *a*, downwards to a casing *t* at the bottom of the cylinder. Here the mixture of oil and condensed vapour or the condensed vapour alone, being lighter, collects as an upper layer, floating on the top of the simultaneously condensed water. The former flows over the partitions *u* into the outer part of the casing, whence it is withdrawn through the pipe *w*, whilst the latter is removed through a tap *e*. Air and uncondensed vapours escape through a pipe *y*.

Another form of the condenser consists of a cylinder in which a system of vertical tubes is arranged in layers between horizontally placed baffle-plates and sheets of wire gauze. The outer cooling-jacket is, in this modification, dispensed with, the cooling water circulating directly outside the pipes.—E. B.

Separators; Impts. in Centrifugal ——. Aktiebolaget Separator, Stockholm. Eng. Pat. 20,276, Sept. 20, 1904. Under Int. Conv., Oct. 3, 1903.

THE claim relates to improvements in centrifugal separators described in Eng. Pat. 14,128 of 1902. The heavier liquid, instead of being discharged through a hollow screw in the neck of the drum, is discharged through a slot or slots *d*, formed in the neck of the drum and the discharged liquid is thrown clear of the drum casing *a2* by the flange or collar *m*. The lighter liquid is discharged through the hollow screw *h, l, i*, placed in the upper portion of the neck of the drum and provided with the inlet *g*. —W. H. C.

Separators; Impts. in Centrifugal ——. M. K. Bamber, Colombo, Ceylon. Eng. Pat. 23,070, Oct. 26, 1904.

THE separator consists of a conical drum *a*, carried by the spider *b* on the shaft *c*, which is rotated in the bearing *d*, by the pulley *e*. The bottom of the drum is formed by a plate of "spring steel" *f*, secured to the shaft *c*, and abutting against, but not fastened to the bottom flange of the drum *a*. The material to be separated is fed into the drum and the solid matter collects in the angle at the bottom; when the weight of the accumulated solids is sufficient to overcome the elasticity of the "spring steel" bottom, the edge of the latter is deflected downwards and allows some of the solid matter to pass out. The extruded solids collect in the outer casing *g*, from which they are expelled on to the conveyor *l*, by the scrapers *i, i*, through

the opening *k*. (See also Eng. Pat. 27,473 of 1902; this J. 1903, 1188).—W. H. C.

Water or other Liquid; Extraction of — from Mineral, Vegetable and Animal Substances. Meister, Lucius und Brüning. Eng. Pat. 24,670, Nov. 14, 1904. XIA., page 1072

Secret Manufacturing Processes of Chemical Treatment; Means for and Methods of Carrying out — G. Wilkinson, Harrogate. Eng. Pat. 1769. Jan. 30, 1905.

THE reservoir containing any liquid of secret composition, the nature of which it is desirable to hide from the men engaged in any process in which it is to be added to another body, is enclosed in a locked casing along with a measuring and diluting apparatus. The manipulation is effected from without the casing and the "secret" liquid is delivered by a siphon passing through the wall into a mixing tank placed without. The apparatus may be so arranged that the liquid is not delivered by the siphon into the mixer until the agitator in the latter has begun to work. In this way no sample of the secret liquid can be got until it is mixed with the liquid previously placed in the mixer. This may be effected by causing the agitator to revolve before the vacuum pump, which starts the siphon, has begun to work.—W. H. C.

Furnaces; Impts. in — T. Suzuki, Tokio. Eng. Pat. 3015, Feb. 14, 1905.

THE invention relates to furnaces having a distilling chamber located within the primary combustion chamber, air-heating flues in the walls of the furnace, a trunk in which the products of distillation and primary combustion are mixed with heated air and from which they are delivered into a secondary combustion chamber, placed below the boiler or other apparatus for the utilisation of the heat. The claim is for providing the secondary combustion chamber with a jacket, so that a second supply of heated air is added to the mixture at its entry into the secondary combustion chamber.—W. H. C.

Furnaces and the like; Manufacture of Refractory — J. Bach, Riga, Russia. Eng. Pat. 7599, April 10, 1905

FURNACES constructed of ordinary hard burnt bricks are rendered highly refractory by lining them with an unburnt material, in the moist state, which is composed of 10–80 per cent. of pure aluminium hydroxide, mixed with pulverised quartz, fire-clay, or washed and purified chromium ore. The furnaces are slowly heated until the material is dried and completely burnt.—R. L.

Filters; Impts. in — A. J. Boulton, London. From E

Goldman and Co., Chicago, Ill. Eng. Pat. 8984, April 28, 1905.

THE filter consists of a cylindrical casing A closed by the top and bottom plates A¹ and A² secured by bolts A³. The outlet of the filter is made up of the tube sections A⁴, b² and c⁵, arranged as shown in the figure. The sections b⁴ and b² carry distributing plates B, B¹, and B², composed of radially corrugated discs b covered with filter-cloth b⁹ secured to the discs by the rings b¹⁰ and fastened to the flange rings or sections b¹ and b² by the flanges and collars b⁶, b⁷ and b⁸. The sections c⁵ carry the collecting plates C placed alternately with the distributing plates and formed of radially and concentrically corrugated discs c, covered with filter-cloth c⁹ on both sides, and provided with flanged outer edges c⁶. The space f² between the discs contains the filtering medium, and the liquid to be filtered enters through the pipe f³, passes into the annular space f and thence through the openings f¹ into the distributing plates and through the filtering medium into the collecting plates C. It then flows through the corrugations in the central discharge channel D.—W. H. C.

Filter; An Improved —. H. Lieberich, Neustadt, Germany. Eng. Pat. 13,247, June 27, 1905.

THE claim is for a filter in which the delivery pipes pass through rings on the frames of the filter-plates, the delivery pipes having slots which register with openings in the plates, through which the filtered liquid flows into the slots and pipes. Should only a few plates be needed, the slots in the parts of the delivery pipes projecting beyond the last plate are closed by means of long caps which fit over the pipes and are held in position by screws passing through the closed ends of the delivery pipes. The screws and caps also serve to keep the plates pressed together and the joints are made with strips of rubber or the like, provided with rings to admit the passage of the delivery pipes.—W. H. C.

Gases, Dust-laden Air, and the like; Method of and [Centrifugal] Apparatus for Purifying Blast Furnace —, and for dissolving Gases and other matter in Liquids. E. Barthelmess, Neuss am Rhein, Germany. Eng. Pat. 12,533, June 16, 1905.

VERTICAL rotary disc is mounted within an upright casing, which it divides into two compartments, communicating with each other all round the periphery of the disc. The disc is provided on both sides with concentric series of horizontal pins or rods which, as the disc rotates, pass between similar pins or rods, extending inwards from the sides of the casing, the whole presenting the appearance of a disintegrator cage. The gas to be washed, and the wash-water, are introduced at one side of the disc, near its centre: they are thrown violently to the periphery by the centrifugal action: the water and impurities flow out through a drain at the bottom of the casing; whilst the gas passes through the peripheral space round the disc into the next compartment, then upwards towards the axis, and out through a central opening in the casing.—H. B.

UNITED STATES PATENTS.

Extractor. W. H. Teas, Ridgway, Pa., U.S.A. U.S. Pat. 799,111, Sept. 12, 1905.

THE apparatus claimed, comprises a boiler, an extracting chamber, an internal vessel with perforated bottom for adding the material, a dome provided with a condenser, and an automatic siphon for returning the extract from below the perforated bottom to the boiler, and a second siphon, having its bend at a somewhat lower level than that of the automatic one, and with its longer leg, which can be closed by a stopcock, opening outside the extractor.—M. J. S.

Filter-press. C. C. Thompson, East Liverpool, Ohio. U.S. Pat. 799,417, Sept. 12, 1905.

THE plates or sections forming the filter are recessed on both sides, and the filter-cloth is hung over the upper edge and covers the recessed portion of the plate. The

upper edge of the plate is cut away to form an opening through which the material to be filtered is fed into the spaces between adjacent plates. An expansible top piece is bolted on to the upper edge of each plate to clamp the cloth in position, and to form a cover to the space through which the material is fed.—W. H. C.

Retort. G. Ketchum, Cutler, Ga. U.S. Pat. 799,470, Sept. 12, 1905.

THE retort consists of an outer casing A fitted with the "socket" B connected to a steam pipe C. An inner casing D fits into the outer casing A, and is kept in position by the blocks E, which fit on the guide-rails F. The inner casing has a perforated cover G and a hinged bottom H, which has a "nipple" K fitting into the socket B, and a perforated steam-distributing cone M arranged over the steam inlet.—W. H. C.

FRENCH PATENTS.

Emulsifying, Subdividing and Rendering Homogeneous, Liquids and Semi-liquids, and for Crushing Fatty or Albuminous Particles; Apparatus for —. C. Petitpierre. Fr. Pat. 353,753, April 28, 1905.

THE apparatus claimed consists of a hollow cylinder capable of resisting high pressure and provided with two branch pipes, one at the bottom and one at the side, for the introduction and removal of material. At the top is a chamber in which slides a piston rod, the end of which is hollowed out. At the bottom of the cylinder is fixed a central rod, the button-shaped head of which can pass into the hollow of the piston; and this rod supports several perforated discs, each with radiating grooved channels on their surface. The liquid material introduced into the chamber surrounding the discs, is driven by the pressure through the channels, and thus becomes intimately mixed and sub-divided, as it passes into the central channel formed by the central openings in the discs.—C. A. M.

Separating Solids from Liquids; Centrifugal Apparatus for —. Aktiebolaget Separator. Fr. Pats. 354,414 and 354,415, May 18, 1905. Under Int. Conv., May 27, 1904.

SEE Eng. Pats. 10,862 and 10,873 of 1905; this J., 1905, 958.—T. F. B.

II.—FUEL, GAS, AND LIGHT.

Coals; Contribution to our Knowledge of —. E. Donath. Chem.-Zeit., 1905, 29, 1027–1028.

THE author describes the action of nitric acid (1:10) on coals, and shows that a distinction can be drawn between lignites (brown coals) and pit-coals. On gentle heating

with nitric acid, lignite is attacked with formation of a large number of products, some of which produce a red coloration. Pit-coals are not attacked. As a red coloration is not given by heating cellulose with nitric acid, but is obtained from several varieties of wood and wood charcoal, lignite is supposed to have its origin in substances which contain lignin. (See also Friswell, this J., 1905, 482 and 526; also Proc. Chem. Soc., 1892, 9.)

—C. E. F.

Nernst Lamp: Inter-Relation of Ballast and Glow in the —. L. A. Tervén. Elect. World and Eng., 1905, 46, 305–308; Electrician, 1905, 55, 906–908.

To compensate for the large increase in current and the consequent destruction of the Nernst filament by increase of voltage of the line above the normal, a ballast or bolstering resistance is employed, placed in series with the glow. This ballast consists of a fine iron wire sealed into a glass tube containing hydrogen. Iron wire is employed since this metal has a large positive temperature coefficient of resistance, and it is so proportioned that its normal temperature is of that value at which this coefficient is a maximum. The author shows by curves the sensitiveness of the ballast, and the impossibility of replacing it by an ordinary resistance in series with the filament.—R. S. H.

Tantalum Lamp: Tests of the —. W. Ambler. Electrician, 1905, 55, 941–942.

THE following measurements indicate the efficiency of the 110 volt tantalum lamps, as compared with the ordinary incandescent carbon filament.

	Watts per mean horizontal candle power.	Watts per mean spherical candle power.
Clear bulb, tantalum...	1.75	2.23
Frosted bulb, tantalum.	2.0	2.67
Carbon	3.1	3.72

Curves are given showing the distribution of the light from the three lamps. From these, it is evident that although the tantalum lamps give much more light in a horizontal direction, the amount from the tip of the lamp is much less than from the carbon filament lamp, despite the fact that this was one with a single-curl filament. The change of candle power, with change of voltage, is much less marked in the case of tantalum than with the ordinary filament of carbon. It requires practically twice the percentage change of voltage across the tantalum lamp of that across the carbon lamp, to cause the same change of light. In conclusion, the author enters into calculations, which show that at the present high price of the new lamp, its adoption only results in marked economy when the cost of electric current for lighting is fairly high.—R. S. H.

Coal: Determination of Sulphur in —. O. Brunck. XXIII., page 1086.

Petroleum and Liquid Fuels: Determination of Sulphur in —. A. Goetzl. XXIII., page 1086.

ENGLISH PATENTS.

Incandescent "Fuel" for Gas and Oil-Gas Fires. T. D. Kelly and W. J. Billington, Southend. Eng. Pat. 1671, Jan. 27, 1905.

"METALLIC or basic oxides or carbonates and a silicate and an alkali or alkaline earth" (for example, bog ore in its natural state, mixed with barium carbonate), are powdered together, mixed with water, moulded into desired forms, and baked in an atmosphere of carbon dioxide, for the production of gas-fire "fuel."—H. B.

Smoke: Means for Treating Coal — for Effecting its Combustion. W. Thomas, London. Eng. Pat. 7499, April 8, 1905.

To effect the combustion of the particles of carbon in smoke, the latter is passed, together with steam, into a diffusion chamber of considerably larger area than that

of the chimney, and of considerable height in relation to its diameter. The chamber is provided with two diaphragms, the lower one being perforated with large, and the upper one with smaller holes. The space between the perforated plates is closely packed with asbestos. The asbestos packing is heated to incandescence by a gas ring burner, located below the lower diaphragm.—R. L.

Gas: Process and Apparatus for the Manufacture of, Illuminating —. P. Busse, Crosta, Saxony. Eng. Pat. 26,246, Dec. 2, 1904.

Gas Producers. J. S. Daniels and T. H. and J. Daniels Ltd., Stroud. Eng. Pat. 1307, Jan. 23, 1905.

To overcome the difficulty experienced in quickly obtaining the supply of steam required for the proper production of gas, on starting a suction producer, a chamber, adapted to provide a large evaporating surface for generating steam from water fed upon it, is arranged below the enclosed ashpit, and through this chamber the gases from the producer are led on their way to the scrubber. The top of the chamber consists preferably of flat sheet- or plate iron, forming the floor of the ashpit. Water is fed into the ashpit, on to this plate, and the steam generated is taken up by the air supply, which is drawn through the ashpit into the producer.—H. B.

Gas Producing Apparatus and Method of Working Same. L. G. Vedy and J. Bilbie, London. Eng. Pat. 3174 Feb. 15, 1905.

To the gas outlet of the generator is attached a vertical water-vaporiser, constructed of four concentric tubes. The annular spaces between the central tube and the second tube, and between the third and outermost tubes are adapted to be filled with water, whilst the hot gas flow first downwards between the second and third tubes and then up through the central tube to the scrubber. A steam dome surmounts the tubes, and the steam collecting within it is led into the generator beneath the fire-bars. On starting the generator, water is admitted slowly to the innermost annular space, which then constitutes a starting vaporiser of small water-capacity and large heating surface; and afterwards, larger quantities of water are passed through it, so that it serves to cool the gases, and water is also led through the outermost annular space, which then serves as the main vaporiser.—H. B.

Gas Producers: Impts. in. [Three-way Cock] W. H. Moore and F. H. Livens, Lincoln. Eng. Pat. 12,059, June 9, 1905.

THE pipe connecting the producer with the scrubber and with the blow-off pipe is provided with a three-way cock having a cylindrical or tapered plug, to either end of which the handle may be attached, so that the cock may be worked from either side.—H. B.

Gas: Apparatus for Washing and Scrubbing — Kirkham, Hulett and Chandler, Ltd., and S. Hersey Westminster. Eng. Pat. 24,467, Nov. 11, 1904.

IN gas-washing apparatus of the type in which discs rotating in tanks containing the washing liquor, are built up of segments of material affording a large wetted surface, the patentees construct each segment of several sheets of corrugated metal or wire gauze, laid one against the other, with the corrugations of the sheets alternately at right angles, or at some other angle, to prevent the sheets from fitting closely together; or the sheet may be laid upon flat boards or plates for separating the corrugated portions. The free passage of gas and water into and from the interior of the segment is thus allowed.—H. B.

Gas Producer. A. Fichet and R. Heurtey. Fr. Pat. 350,047, July 8, 1904.

THE apparatus consists of two superimposed producers; the fuel is burned partially in the upper one, and falls into the lower one, where the combustion is completed. An annular space, for withdrawal of the gas produced in both generators, is left round the opening by which they communicate, and an annular boiler, for generating the necessary steam, is provided at the same place. Air, or air and steam, are admitted to the upper producer through water-cooled pipes, which extend more or less, as desired, into the mass of fuel. The lower producer, if the ash of the fuel is but slightly fusible, is of the ordinary type; but if the ash is very fusible and apt to clinker, the base of the producer is formed like a cupola, with crucible, tuyères, and tap-hole, a fluxing material being added, to enable the ash to be removed in the form of slag.—H. B.

Coal; Process of Distilling — for the Production of Coal Gas and Coke. Cie. pour la Fabrication des Compteurs et Matériel d'Usines à Gaz. Fr. Pat. 350,063, July 15, 1904.

THE distillation of the coal is effected in a generator, by passing through the fresh fuel a current of coal-gas, which has been heated by leading it through a body of red-hot

coke. The apparatus may consist of two generators, side by side, the first containing fresh coal, and the second red-hot coke from a previous operation. Coal-gas is passed downwards through the coke in the second generator and then upwards through the coal in the first; when the distillation is completed, the second generator is emptied, and charged with fresh fuel, the first generator now acting as heater for the gas. When the heating column has been cooled somewhat by the stream of gas, it is raised to incandescence by admitting temporarily a blast of air, the products of combustion being led off by a special conduit. Instead of two or more generators, a single generator, resting in a water seal, may be employed, fresh coal being fed in at the top, and coke withdrawn at the bottom. Inlets for coal-gas are provided near the bottom, and outlets at the top; whilst, for heating the coke, when it has cooled to the permitted degree, inlet pipes for air and outlet pipes for the products of combustion are arranged at suitable intermediate points.—H. B.

Gas and Air [Carburetted Air] rich in Combustible matter; Process and Apparatus for the Production of a Mixture of — M. Caracristi. Fr. Pat. 353,674, April 25, 1905.

THE apparatus consists of three superimposed chambers. The top chamber is a reservoir for the volatile hydrocarbon to be used. The second one, constituting the carburettor proper, contains a series of horizontal plates, on to which the hydrocarbon flows from above, pursuing a zig-zag course downwards over the plates, whilst the air supply, which enters beneath the lowest plate, passes upwards in the contrary direction. The lowest chamber encloses a rotating pump, of the meter drum type, driven by clock-work or the like, and serving to draw air through the carburettor and discharge the carburetted air.—H. B.

Suction Gas Generator Plant. C. Whitfield. Fr. Pat. 353,712, April 26, 1905. Under Int. Conv., April 27, 1904.

SEE Eng. Pat. 9608 of 1904; this J., 1905, 793.—T. F. B.

Gas Producer. T. Stapf. Fr. Pat. 353,802, April 29, 1905.

TO prevent the adhesion of clinker to the walls of the producer surrounding the hottest zone of the fuel, the masonry at this part is replaced by an annular metallic section, serving as a cooler, which is bolted on to the metal shell of the producer, or otherwise affixed to an easily accessible part, to facilitate renewals. The cooler may be provided with closed, or partly closed, channels for the circulation of water, steam, or air; or, if the fuel is of a wet nature, such as peat, the channels may be dispensed with and the annular body may be provided with a fluted surface, the loss of heat by radiation being then sufficient.—H. B.

Gas Furnace having Multiple Vertical Retorts for the Simultaneous Production and Admixture of Coal Gas and Water Gas. A. Rummens. Fr. Pat. 353,865, May 2, 1905.

SEVERAL vertical retorts are grouped together in one setting and are heated by means of one or more generators, operating by natural draught. Each retort has double walls, the exterior wall having parallel sides, whilst the interior wall, which is provided with vertical slots to let the gas pass off without ascending through the hot coke, is of conical form, to facilitate the discharge of the coke. Under each retort is a closed chamber, into which the coke is discharged and which encloses a vaporiser, heated by the coke and designed to generate sufficient steam for the production of a limited proportion of water-gas. The vaporiser consists of three vertical, concentric tubes, surrounding a rod, which may be used as a poker; water is admitted into the annular spaces between the tubes, and the steam produced is led up into the retorts.—H. B.

Sulphur and Cyanides from Spent Oxide, &c.; Process and Apparatus for the Extraction of — J. J. M. Bécigneul. Addition dated April 26, 1905, to Fr. Pat. 345,071, July 23, 1904. VII., page 1067.

is liberated by acetic acid. It is only slightly soluble in water and has both acid and basic properties. On heating 0.5 gm. of dianilidomaleic acid dimethyl ester with 2.5 grms. of dry potassium hydroxide over a naked flame and pouring into ice and water, a blue coloration, due to indigo, was obtained, and was increased by passing a current of air through the liquid, but the yield was very small. On merely heating to 320° C. no indigo was obtained. Better results were obtained by melting either the dimethyl ester or the sodium salt with sodium amide. 1.5 grms. of finely-powdered sodium amide is mixed with a very little potassium hydroxide and heated in a test-tube in a paraffin bath to 200° C. 0.5 gm. of the disodium salt of dianilidomaleic acid is then added during a few minutes with constant stirring. In five to six minutes the melt is finished and the evolution of ammonia becomes less. Water is carefully added, a current of air blown through the solution, the indigo filtered off and washed successively with dilute hydrochloric acid, water, alcohol, pyridine, alcohol and ether. The yield is very variable and usually unsatisfactory.—E. F.

α-Anthramine and α-Anthrol. H. Dienel. Ber., 1905, 38, 2862—2867.

WHEN anthraquinone-*α*-monosulphonic acid is reduced with zinc dust and ammonia, the zinc-ammonium salt of anthracene-*α*-monosulphonic acid is obtained in the form of colourless needles. By converting the latter into the potassium salt, melting with potassium hydroxide at 250°—260° C. and decomposing the melt with hydrochloric acid, *α*-anthrol $\text{C}_{14}\text{H}_9\text{OH}$ is formed in light brown flocks, easily soluble in most solvents with blue fluorescence, and crystallising from alcohol in leaflets or small needles melting at 150°—153° C. The acetyl derivative forms colourless needles, which melt and decompose at 128—130° C., and yield on oxidation acetyl-erythrohydroxy-anthraquinone. *α*-Anthramine $\text{C}_{14}\text{H}_9\text{NH}_2$ is formed by heating 1 part of anthrol with 3 parts of acetamide for eight hours at 260° C. and thereafter for one day at 235° C. From alcohol, in which it dissolves readily with yellowish brown colour and green fluorescence, it separates in golden yellow leaflets melting at about 130° C. It is more readily soluble in most solvents than the *β*-compound, behaves like the latter in its reaction with bromine and nitric acid, but differs therefrom in its behaviour with arsenic acid, the *α*-compound when heated therewith melting to a mass having a greyish-green colour, whilst the *β*-compound yields a fine blue colour. The acetyl compound forms green needles melting at 198° C. and is converted into the corresponding aminohydroxyanthraquinone by oxidation with chromic acid. The dihydride obtained by reduction crystallises from alcohol in colourless needles, whilst *α*, *α*-dianthramine obtained by boiling *α*-anthramine with glacial acetic acid forms greenish-yellow leaflets melting at 204° C.—D. B.

2,3-Dihydroxyanthracene. K. Lagodzinski. Annalen, 1905, 342, 90—111.

THE author describes the synthesis of 2,3-dihydroxy-anthracene. By the action of phthalic anhydride and aluminium chloride on veratrol, 3,4-dimethoxy-1,2'-benzoyl-*o*-benzoic acid is obtained. It forms colourless prisms, yields soluble salts with alkalis and ammonia, and reacts with phenylhydrazine with the production of 2-phenyl-4-veratryl-phthalazone. When heated with strong sulphuric acid, it is converted into the dimethyl ether of hystazarin, which yields hystazarin in theoretical quantity when hydrolysed with hydrogen bromide at 170° C. and 2,3-dimethoxyanthracene when reduced with zinc dust and dilute ammonia. The dimethoxy compound crystallises from alcohol in white, short prisms, melting at 204° C., and is converted into 2,3-dihydroxyanthracene on hydrolysis with hydrogen iodide. The latter forms straw-yellow leaflets, readily soluble in organic solvents, does not react with oxidising agents at the ordinary temperature, but is decomposed when heated therewith and apparently without the formation of a quinone.—D. B.

1,2-Anthraquinone. K. Lagodzinski. Annalen, 1905, 342, 59—89.

2-ANTHROL was prepared in a pure form by fusing sodium 2-anthracenesulphonate with potassium hydroxide at 300°—310° C. for 30 minutes, cooling the melt and decomposing it with hydrochloric acid diluted with ice water. From this compound 1,2-nitroso-anthrol was obtained by dissolving in boiling alcohol, filtering the hot solution, cooling the filtrate to 30° C., adding zinc chloride, gradually introducing sodium nitrite, heating for two hours at 50—60° C., and finally boiling for two or three hours in a reflux apparatus. It forms orange-yellow needles sparingly soluble in organic solvents. By reducing the nitroso compound with stannous chloride and hydrochloric acid or hydrogen sulphide in an alkaline solution 1,2-amino-anthrol was obtained. By treating the salts of the latter compound in the cold with weak chromic acid or ferric chloride and dilute sulphuric acid, 1,2-anthraquinone was formed in theoretical quantity. It crystallises from alcohol in orange needles, dissolves sparingly in organic solvents, although more readily than the 9,10 compound, melts and decomposes at 185—190° C., reacts with nitric acid to form a mononitro derivative, and gives with strong sulphuric acid a characteristic bluish violet solution. By gently heating its solution in acetic anhydride with *o*-phenylenediamine, 1,2-anthraphenazine was obtained in the form of yellow leaflets melting at 221°—222° C. without decomposition. When 1,2-triacetylaminanthrol is subjected to oxidation, the corresponding anthraquinone is obtained crystallising in pale yellow needles which melt at 189° C. and yielding on hydrolysis 1,2-aminohydroxyanthraquinone identical with Liebermann's *α*-aminoalizarin. The conversion of the latter into alizarin was effected by heating with strong hydrochloric acid at 250° C. 1,2-anthrahydroquinone formed by reducing the new anthraquinone with zinc dust and acetic acid crystallises in yellowish-green leaflets melting at 131° C. It dissolves readily in organic solvents and regenerates 1,2-anthraquinone when subjected to oxidation. The diacetyl derivative forms pale yellow crystals, dissolves extremely readily in solvents, melts at 145° C. and gives on oxidation diacetylalizarin, identical with Bayer's product. The formation of alizarin in the foregoing experiments, affords a new synthesis of this dyestuff from anthracene whilst the quantitative production of anthraphenazine is direct evidence as to the ortho-position of the two hydroxyl groups in alizarin.—D. B.

Azo Dyestuffs; General Method for Determining the Constitution of —, and a New Mode of Formation of Diazo Compounds. O. Schmidt. Ber., 1905, 38, 3201—3210.

THE author finds that azo dyestuffs are decomposed smoothly, by strong nitric acid, generally with formation of the corresponding diazo compound on the one hand, and of the nitro derivative of the second component on the other. The reaction thus affords a means of determining the constitution of azo dyestuffs, and also represents a new mode of formation of diazo compounds. In carrying out the reaction, the dyestuff is introduced gradually into 10—20 times its weight of red fuming nitric acid at the ordinary temperature, and the mixture is cooled by ice. The dyestuff dissolves in the acid and is decolorised. After standing for about 10 minutes, the solution is poured on to ice. The following cases may now arise:—(1). Both the diazo compound and the nitro derivative are insoluble in water. They are filtered off, and the nitro derivative is separated by extraction with an organic solvent. (2). Both the diazo compound and the nitro derivative are soluble in water. The nitro derivative is extracted from the solution by an organic solvent, either before or after precipitation of the diazo compound as an insoluble azo dyestuff. (3). If one of the products is soluble and the other insoluble, they can be separated by filtration. (4). In the case of polyazo compounds, several different diazo compounds and nitro derivatives may be produced, and a special process of separation must be worked out for each case.

Azo dyestuffs containing hydroxyl or primary amino groups are alkylated before treatment, otherwise the

fuming nitric acid oxidises the phenol and diazotises the amino group. Up to the present the following facts have been demonstrated:—(1). Azo dyestuffs containing auxochrome amino or hydroxyl (or alkoxy) groups in the position para to the azo group, are split up into their components by red fuming nitric acid. (2). If the amino or hydroxyl (or alkoxy) group is ortho to the azo group, the decomposition proceeds smoothly only in the case of β -naphthol dyestuffs, whilst with dyestuffs from *p*-cresol, the reaction only takes place to a limited extent. (3). If the auxochrome group is in the *m*-position, the reaction either fails entirely or takes place only to a very limited extent. (4). Other azo compounds such as azobenzene and *p*-azotoluene are not converted into diazo compounds by nitric acid or only in a very limited degree. (5). On decomposing azo dyestuffs with fuming nitric acid, the alkylated amino compound or the alkoxy compound, is obtained in the form of its nitro derivative, whilst the other portion of the molecule is recovered as the diazo compound. (6). Azoxy compounds containing an amino group para to the azoxy group are also decomposed by red fuming nitric acid, with formation of diazo compounds. The reactions mentioned under (1) and (6) are also caused by chromic acid and permanganic acid dissolved in glacial acetic acid. In the case of azo compounds the action appears to be in the first place an oxidation to the corresponding azoxy compound, the latter being afterwards split up owing to the replacement of the azoxy group by the nitro group.

The following examples of the reaction are given:—Helianthin (sodium salt of dimethyl-*p*-aminoazobenzene-*p*-sulphonic acid) gave good yields of diazobenzene-sulphonic acid—isolated in the form of its compound with β -naphthol—and of *o*-*p*-dinitrodimethylaniline and tetranitromethyl aniline. *p*-Nitro-*p*-methoxyazobenzene yielded *p*-nitro-diazobenzene and *o*-*p*-dinitroanisole. Orange II (sodium salt of the dyestuff from β -naphthol and diazotised sulphanic acid) yielded the diazo compound of sulphanic acid and an impure nitro derivative of β -naphthol. Good yields of the corresponding diazo compounds were also produced from β -naphtholazobenzene-*o*-carboxylic acid (from diazotised anthranilic acid and β -naphthol), *p*-ethoxy-*p*-hydroxyazobenzene, *p*-hydroxyazobenzene-sulphonic acid, benzene-azo- β -naphthol, *p*-ethoxybenzeneazo- β -naphthol, and tetramethyl-*p*-*p*-diaminoazoxybenzene. On the other hand, *m*-hydroxyazobenzene, the dyestuff from diazotised anthranilic acid and *p*-cresol, azobenzene, *p*-azotoluene, and tetramethyl-*m*-*m*-diaminoazobenzene gave only small yields of diazo compounds.—A. S.

Oxazones; Contribution to the Knowledge of — R. Gnehm and L. Bauer. J. prakt. Chem., 1905, 72, 249–277.

THE authors prepared Gallamine Blue, Celestine Blue B, and Corein Blue 2R under various conditions, and give a detailed description of what they consider to be the best method. The yields obtained are shown in tabular form. Gallamine Blue (*p*-dimethylaminodihydroxy-carboxylic acid amide-phenoxazonium chloride) and Celestine Blue B (*p*-diethylaminodihydroxy-carboxylic acid amide-phenoxazonium chloride) are obtained by the action of *p*-nitrosodimethyl- and *p*-nitrosodiethylaniline respectively on gallamic acid (see Eng. Pat. 2941 of 1889; this J., 1889, 981). The free bases obtained by pouring a solution of the dyestuff in dilute sulphuric acid into dilute ammonia are blue substances insoluble in water. The formula

agrees best with the analytical results in each case; but the authors consider the anhydride constitution

far more probable in view of the behaviour of the bases towards arylsulphonic chlorides.

The benzenesulphonic acid ester of Gallamine Blue and Celestine Blue B bases and the benzene-, *o*-toluene-, and *p*-toluene-sulphonic acid esters of Prune base (the methyl ester of Galloeyanine) were prepared, and it is shown clearly that these bases react with only one molecule of arylsulphonic chloride, and that therefore the galloeyanine dyestuffs contain only one hydroxyl group. The benzene sulphonic acid ester of Gallamine Blue is insoluble in dilute alkalis. It was obtained in microscopic moss-green crystals decomposing gradually above 230° C. Its constitution may be represented by the formula

The aryl sulphonic esters of Prune base have a similar constitution, but contain a methoxyl group in place of the amino group in the above formula. It is therefore remarkable that Prune should yield a triacetyl derivative, when heated with acetic anhydride and fused sodium acetate (see also Nietzki and Otto, Ber., 21, 1736, this J., 1888, 559; also this J., 1893, 139, and also Möhlau and Klümmer, Z. Farben. u. Text. Chem. I., 65; and that the arylsulphonic esters of Prune base yield diacetyl derivatives under similar conditions.

The authors acetylated Prune and its arylsulphonic esters in the presence of a reducing agent and also acetylated the leuco compound of Prune. Both methods lead to the production of identical products, a diacetyl derivative of the leuco compound of Prune and mono-acetyl derivatives of arylsulphonic esters of the same. These substances are not changed into the triacetyl compounds by boiling with acetic anhydride and sodium acetate. Moreover the substances of each series behave very differently on hydrolysis with hydrochloric acid. The triacetyl derivative of Prune on hydrolysis yields a product which may be reconverted into the triacetyl body by treatment with acetic anhydride and sodium acetate, but which is not the same as, and could not be converted into Prune hydrochloride. The diacetyl derivative of the leuco compound of Prune, on the other hand, is readily converted into the corresponding hydrochloride by hydrolysis and thence to Prune by oxidation with hydrogen peroxide. The triacetyl derivative of Prune crystallises in lemon-yellow needles, m. pt. 225° C. It is insoluble in water, but soluble in the cold with greenish colour in alcoholic caustic soda. The diacetyl derivative of the leuco compound of Prune is obtained in yellow needles, m. pt. 168° C.; it is insoluble in water. Both substances dissolve in concentrated sulphuric acid with greenish-blue colour. The constitution of the triacetyl derivative of Prune may be represented by formula I., II., or III. The former two are supported by the behaviour towards alkali and concentrated sulphuric acid; the open chain formula III. by the behaviour towards hydrolysis. Formula IV. represents the constitution of the diacetyl derivative of the leuco compound of Prune.

Zinc or stannous chloride double salts of a number of leuco galloeyanine dyestuffs were also prepared (see Eng. Pat. 21,415 of 1898; this J., 1899, 827). All were found to be unstable substances with the exception of

the Prune derivatives. The preparation of the stannous chloride double salt of leucoprune hydrochloride m. pt. 268° C., is described in detail. It is a fairly stable substance which may be dried at 110°–120° and kept for months without decomposition.

The following diethylanilinoazo bodies used for the foregoing experiments have not previously been described. They were prepared by combining diazobenzene, toluene, &c., with diethylaniline in acetic acid solution.

Benzeneazodiethylaniline crystallises from alcohol in orange-brown needles melting at 97.8° C. The hydrochloride crystallises from absolute alcohol in flat, golden orange needles, m. pt. 182° C. The sulphate forms garnet red leaflets, m. pt. 137° C. *p-Toluenazodiethylaniline* is very similar, m. pt. 113° C. The hydrochloride and sulphate both melt at 179° C. *Naphthalene-α-azodiethylaniline* crystallises in shimmering, green needles from glacial acetic acid, m. pt. 108° C. The sulphate crystallises from alcohol in brownish leaflets, insoluble in water, m. pt. 189.5° C. *Naphthalene-β-azodiethylaniline* is obtained from ligroin (light petroleum) in dark brown needles or leaflets melting at 137.6° C. The hydrochloride (golden brown leaflets) melts at 174° C.; the sulphate at 171° C. The above bases are insoluble in water, but readily soluble in many organic solvents. The salts of the two first-named are decomposed by water even in the cold.—H. L.

Aniline Black; Constitution of —. R. Vidal. Z. Farben- und Textil.-Ind., 1905, 4, 458.

p-AMINOHYDROXYDIPHENYLAMINE was produced by heating quinol with *p*-phenylenediamine in alcoholic or phenolic solution in presence of zinc, to about 180° C., in a closed tube. By prolonging the reaction, the "auto-condensation" product was obtained, *viz.*, the leuco base of Emeraldine and Azuline. These two dyestuffs, obtained by oxidation of the leuco base with air in acid and alkaline solution respectively, both give Aniline Black on oxidation with chromic acid. This process serves as further confirmation of the synthesis of Aniline Black by anhydride formation, starting from *p*-aminophenol. It is also considered as a further confirmation of Goppelsroeder's formula for Aniline Black:—

A VERY soluble dyestuff, especially suitable for machine dyeing, is produced by sulphonation of the azo dyestuff obtained by combining 1-diazo-2-naphthol-4-sulphonic acid, or its anhydride, with β-naphthol. The new dyestuff shows, when dyed on wool and subsequently treated with bichromate, the same excellent fastness against light, milling and potting as the original products. H. L.

Thiazol Sulphonic Acids; Production of —. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 353,928, March 6, 1905. Under Int. Conv., May 13, 1904.

BENZYLIDINE compounds obtained by condensing aromatic aldehydes with aromatic aminosulphonic acids are heated with alkali sulphides and sulphur, or with alkali polysulphides, or with substances or mixtures reacting in an analogous manner. In place of these benzylidineaminosulphonic acids, mixtures of aldehydes and aromatic aminosulphonic acids may be employed. Thus benzaldehyde and 2.8-aminonaphthol-6-sulphonic acid yield the compound

a product which combines with diazo substances, producing substantive cotton dyestuffs, which may be re-diazotised on the fibre and combined with β-naphthol. &c. Other aminosulphonic acids, such as 2.5-aminonaphthol-7-sulphonic acid, 1.5-aminonaphthol-7-sulphonic acid, 1.8-aminonaphthol-4.6-disulphonic acid, 1.5-, 2.6-, naphthylamine-sulphonic acids, 2-naphthylamine-6-chloro-4-sulphonic acid, *p*- or *m*-sulphanilic acid, &c., and also other aldehydes may be employed.—H. L.

Dyestuffs of the Anthracene Series, and Intermediate Products for their Production; Preparation of —. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 354,076, April 28, 1905. Under Int. Conv., Sept. 23, 1904.

1.4.8-TRIHIDROXYANTHRAQUINONE (see Eng. Pat. 17,589 of 1904; this J., 1905, 725), and 1.2.5.8-Tetrahydroxyanthraquinone (Alizarin Bordeaux) are sulphonated in the presence of boric acid. A good yield of a monosulphonic acid, probably the 1.4.8-trihydroxyanthraquinone-7-sulphonic acid and 1.2.5.8-tetrahydroxyanthraquinone-3-sulphonic acid respectively, is produced in each case, and may be isolated directly from the melt in a pure state. Both acids are stated to be of great technical value, as they yield green dyestuffs on condensation with primary aromatic amines. The dyestuff obtained by condensing 1.4.8-trihydroxyanthraquinone-sulphonic acid with *p*-teluidine (2 mols.) is identical with that prepared by sulphonating 1.4-di-*p*-tolylidiamino-8-hydroxyanthraquinone in the presence of boric acid. (See Fr. Pat. Application, April 19, 1905.)—H. L.

Dyestuff especially suitable for the Manufacture of Lakes; Production of an [Azo] —. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 353,816, April 29, 1905. Under Int. Conv., Jan. 13, 1905.

DIAZOTISED benzidinesulphonic disulphonic acid is combined

with 2 mols. of phenylmethylpyrazolone. The resulting dyestuff dyes wool orange shades. It is particularly adapted to lake manufacture in the usual way, the lakes being of a brilliant reddish-orange colour, and very fast to light, water and alkalis.—T. F. B.

Dyestuffs; Preparation of Diazo Derivatives of Ortho-aminonaphthol Sulphonic Acids and Conversion of these Derivatives into [Monoazo] —. Kalle und Co. Fr. Pat. 353,786, April 28, 1905.

A NEW process for diazotising 1,2-aminonaphthol sulphonic acids is claimed (compare Eng. Pat. 10,235 of 1905; this J., 1905, 433; and Ger. Pat. 155,083 of 1903; this J., 1905, 542); as well as the monoazo dyestuffs obtained by combining the diazo bodies with β -naphthol or its sulphonic acids, dihydroxynaphthalenes, resorcinol or aminophenol. (Compare Eng. Pats. 15,025 of 1904, and 16,566 of 1905; this J., 1905, 668, 724; also Fr. Pat. 351,125 of 1905; this J., 1905, 840.) The metallic salts of the diazo-oxy-sulphonic acids in question are obtained by the action of alkali nitrites and the salts of certain metals, such as zinc sulphate or chloride, nickel or copper sulphate, preferably in the presence of a small amount of the hydroxides of these metals, on *o*-aminonaphthol-sulphonic acids in concentrated solution or aqueous suspension.

Example: 48 kilos. of 1,2-aminonaphthol-4-sulphonic acid are mixed and well stirred with a solution of 33 kilos. of zinc sulphate in 33 litres of water, containing a little zinc hydroxide. The latter is formed by the addition of about 3 kilos. of ammonia to the solution. A concentrated aqueous solution of 14 kilos. of sodium nitrite is then added.

Expt. No.	Diazo compound.	Free HCl.	Free HNO ₂ .	Sodium Acetate.	Salt.	Time. Hrs.	Temperature C.	Loss. Per cent.
In grms. per litre.								
1a	25.0	2.0	—	—	—	24	19	0.1

9a	18.7	1.2	0.19	30	—	22	22	50.8
9b	25.4	1.2	0.19	30	—	22	22	54.6

The reaction is completed by warming for two hours at about 40 C., and the mass is then acidified with acetic acid. By filtration and recrystallisation, brilliant bronze needles of the composition $C_{10}H_7(SO_3Zn) \begin{smallmatrix} N:N \\ \diagdown \diagup \\ C \end{smallmatrix}$ may be obtained.

The diazo body need not be isolated for the preparation of the dyestuff, but may be directly combined in very concentrated alkaline solution with β -naphthol, &c., forming, it is stated, the zinc salt of the dyestuff. The latter may be converted by treatment with hydrochloric acid into the free acid, which produces fast black shades on wool, when dyed in an acid bath and with after-treatment with bichromate; but the same result, it is stated, can be obtained by employing the zinc salt directly.

Indophenols; Preparation of Acetylated —. [Sulphide Dyestuffs.] Act.-Ges. f. Anilinfabrikation. Fr. Pat. 353,866, May 2, 1905.

ACETYL-*p*-PHENYLENEDIAMINE is oxidised at a low temperature with phenol or one of its derivatives with a free para position. Excellent yields are thus obtained it is stated. The products may be employed for the production of sulphide dyestuffs, either directly or after elimination of the acetyl group.—H. L.

GERMAN PATENT.

Haematoxylin; Process for Preparing a Solid Colouring Matter [Dyestuff] from —. R. Haack. Ger. Pat. 162,010, July 1, 1904.

SODIUM nitrite acts on haematoxylin or logwood extract in the cold, in concentrated solutions, producing a precipitate which, unlike that obtained by oxidation of haematoxylin in the warm by alkali nitrite, is completely soluble in water; it is probably a condensation product. Its aqueous solution is brown, and dyes chrome-mordanted silk grey shades from dilute solutions, and pure black from more concentrated baths; in this respect also it differs from the above-mentioned oxidation product, which dyes silk in blue to blue-black shades.—T. F. B.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

Paranitraniline; Stability of Diazotised —. C. Schwalbe. Z. Farben- und Textil-Ind., 1905, 4, 433—438.

THE subjoined table gives the results of a series of experiments on the stability of diazotised *p*-nitraniline solutions, under varying conditions; the diazo solutions were prepared from purified Nitrosamine Red, and the determination of the strength of the solutions was carried out by titration with β -naphthol solution:—

Nos. 3a and 3b in the above table show the harmful effect of free nitrous acid on solutions containing free hydrochloric acid; in solutions containing free acetic acid (4a and 4b) this influence is much more marked. In Nos. 2a and 2b, the beneficial influence of salt in presence of free acetic acid is exhibited. In mineral acid solution (1a and 1b) the effect is unnoticeable, since the solution is very stable. The good effect of salt in presence of free nitrous and acetic acids is seen in Nos. 5a and 5b. In Nos. 7a and 7b the effect of excess of hydrochloric acid in presence of free nitrous acid is clearly brought out. The decrease of stability with the increase of concentration of the solutions appears in Nos. 8a and 8b. Nos. 6a and 6b show the large decrease of stability due to increased excess of nitrous acid. In practice, excess of nitrous acid should therefore be carefully avoided. Solutions containing free nitrous acid are also more sensitive to light than those from which it is absent. In conclusion, it is stated that, when great stability is desired (e.g., in printing), Azophor Red, the Nitrazols, or purified Nitrosamine Reds should be employed.—T. F. B.

Sulphur in Albuminoid Substances [Wool]; Condition of —. P. N. Raikow, XXIV., page 1088.

ENGLISH PATENTS.

Silk or Hair [from Casein]; Process for the Preparation of Artificial — F. Todtenhaupt, Köln a/ Rhein, Germany, Eng. Pat. 25,296, Nov. 21, 1904.

CASEIN is dissolved in an alkali solution, which is then passed through forcing nozzles into a dilute acid bath; the threads thus formed are stated to be insoluble and very tough and to contain 15 to 16 per cent. of nitrogen; they resemble natural silk very closely, and burn with difficulty. The alkaline casein solution may be prepared by dissolving 1 part of casein in 3 parts of 10 per cent. ammonia and 4 parts of water.—T. F. B.

Woollen and other Materials; Method and Plant for Removing [by means of Volatile Solvents] Grease and other Impurities from — H. Heymann, Bradford; and H. Hey, J. Smith, H. L. Mitchell and W. H. Askham, Dewsbury, Eng. Pat. 17,437, Aug. 10, 1904.

Two cylinders 2 (see Fig.), fitted with steam pipes or

the material has been sufficiently treated, the solvent is withdrawn from the cylinder. If it be still in a suitable condition, it is again used in the same manner in the second cylinder, being finally allowed, when sufficiently saturated with grease, &c., to run off, through the pipes 37 and 38, into the storage-tanks 6, which, during this operation, are connected with the pump 14. The storage-tanks 6 are then put into communication with the lower part of the cylinder from which the solvent has been withdrawn, and the axle is set rotating at a much higher speed than before, whilst heat and reduced pressure are applied to vaporise the solvent still left in the materials. The materials are thus rendered dry and fit for removal from the cylinder. The solvent received in the tanks 6 is passed from these, through a preliminary heater into a still 7, air being admitted into the tanks to enable this to be done. The oils, &c., which are left in the still are withdrawn through a tap 20, while the vaporised solvent, along with water, is condensed

steam jackets, for heating purposes, and with tightly fitting lids, are provided internally with suitable apparatus for carrying the materials to be treated, e.g., with winches for tissues, or with cages for garments and loose materials, mounted upon axes passing through the cylinders, so as to be rotatable by means of external gearing. When the materials have been placed in the cylinders, a grease-solvent is run to a suitable height into one of the latter from a storage tank 13, while the axle is revolved at a slow speed, to effect the saturation of the materials and the extraction of the grease and other matters from them. Any vapours produced during the operation are drawn by means of a vacuum-pump 14, through a pipe 19, to a separator 15, where they are condensed and whence the recovered solvent is removed for further use. When

and received in a collector 9, whence, after removing the water by means of a tap 10, the solvent passes again to the storage-tanks 13.

The circulation of the solvent is effected better, it is declared, by means of reduced pressure than with compressed air or gas, as, less evaporation takes place by the first than by the second method, and the vapours which are formed are much more easily condensed than is the case when they are mixed with air; in fact, it is stated, if during the working of the apparatus, the vapour be allowed to flow direct from the cylinders 2 through the pipe 19, 17, 37 and 38 to the tanks 13, it will condense on its way and reach the latter in a liquefied state.

Instead of two cylinders, one alone may be employed in the process.—E. B.

Volatile Liquids; Apparatus for Separating and Condensing the Vapours of — H. Heyman, H. Rev, J. Smith, H. L. Mitchell and W. H. Askham. Eng. Pat. 17,435, Aug. 10, 1904. I., page 1053.

Benzine Employed for Cleaning Fabrics; Apparatus for Recovering the — E. Delhotel, Paris. Eng. Pat. 7807, April 12, 1905. Under Int. Conv., July 16, 1904.

Velvets, Velveteens and other Pile Goods; Production of Ornamental Patterns on — O. St. L. Davies, Castleton. Eng. Pat. 22,098, Oct. 14, 1904.

IN place of depressing the pile on the portions of the fabric, which it is desired to obtain in relief, by the use of gum, &c., as described in Eng. Pat. 21,427 of 1903 (see this J., 1904, 932), it is found that sufficient depression is produced by merely embossing the fabric with an embossing roller, and subsequently singeing the portions of the pile which are still raised, finally raising, by any suitable means, the parts which have been depressed.—T. F. B.

UNITED STATES PATENTS.

Flax; Process of Retting — C. Vansteenkiste and L. Legrand, Antwerp. U.S. Pat. 799,281, Sept. 12, 1905.

THE flax, contained in a suitable receptacle, is introduced repeatedly (being frequently raised and lowered) by mechanical means, into a scouring tank, and then similarly into a retting tank, filled with water, and containing a constant amount of ferments. The retting tank may be heated by steam or otherwise. After it has been sufficiently treated, the flax is next introduced into a rinsing tank. The water from this latter is passed successively into the retting and scouring tanks, which are provided with false bottoms of linen or similar material. (Compare this J., 1900, 143; 1904, 249; 1905, 84).

—T. F. B.

FRENCH PATENTS.

Alfa [Esparto] and other Similar Plants; Conversion of — into Paper Pulp or Textile Fibres. Mme. M. Kuess, née Solley. Fr. Pat. 354,092, May 8, 1905. XIX., page 1081.

Wool-Washing Machine. G. W. and A. P. Tattersson. Fr. Pat. 352,153, March 7, 1905.

A LOOSE-WOOL washing tank 2 (see fig.) has at its exit-end two squeezing-rollers 1, in front of which is placed a series of rollers 3 which act in the same manner as a travelling-apron. A main driving-shaft 5, communicates its motion to a fork 10, carried by a revolving and oscillating shaft 9, and to a frame 31, bearing a system of rakes 45, and attached to the shaft 9 by means of an arm 42. The apparatus is arranged to operate in the following manner:—As the shaft 9 is moved away from the squeezing-rollers, the fork 10 is lifted above it and is upon the point of entering the water in the tank when the shaft has moved as far back as it can go. During the return of the shaft the fork dips into the bath and lifts upon its prongs a quantity of the loose wool contained in the bath. As the fork approaches the rollers 3, it attains a horizontal position. It then descends upon the rollers for the purpose of enabling the rollers to remove the fibres from it. Simultaneously with this action of the fork, the rake-frame is lifted above the bath, carried back, lowered, and moved forward in the bath.—E. B.

Hydrosulphite [Compound]; Insoluble, Stable, Pulverulent — M. Muntadas. Fr. Pat. 353,765, April 8, 1905.

AN insoluble, stable, pulverulent formaldehyde-zinc hydrosulphite compound is formed by boiling a mixture of sodium bisulphite, formaldehyde, zinc dust and sulphuric acid. The following reaction is stated to take place:—

The insoluble hydrosulphite compound is filtered off, washed, dried, and passed through a sieve. The compound is said to be insoluble in water, acids and alkalis. It can be employed advantageously in discharging dyed textile fabrics; with caustic soda it is said to form a satisfactory discharge for *a*-Naphthylamine Red.—T.F.B.

VI.—COLOURING WOOD, PAPER, LEATHER, &c.

ENGLISH PATENT.

Wood; Method of Colouring — R. Kornmann, Freiburg, Germany. Eng. Pat. 16,316, Aug. 10, 1905. By treating wood with a solution of 4 parts of hydrogen

peroxide (10 vols.) and 1 part of a mineral acid (e.g., hydrochloric acid) and drying, it is stated that it assumes the appearance of old wood; the acid may be subsequently neutralised by ammonia.—T. F. B.

UNITED STATES PATENT.

Feathers; Process for the Preservation of. B. Wolfenstein, Berlin. U.S. Pat. 800,197, Sept. 26, 1905. See Eng. Pat. 11,712 of 1903; this J., 1904, 139.—T. F. B.

VII.—ACIDS, ALKALIS, AND SALTS, AND NON-METALLIC ELEMENTS.

Sulphuric Acid: Refractive Index of —, at Different Concentrations. V. H. Veley and J. J. Manley. Proc. Roy. Soc., 1905, 76A., 469—487.

THE refractive indices of acids containing from 1 to 99 per cent. of sulphuric acid were determined for the three hydrogen lines α , β , and γ and the sodium line, and the temperature coefficients in the neighbourhood of 15° C. measured. The results are tabulated in the paper. The refractive indices show a maximum corresponding approximately with the hydrate $\text{H}_2\text{SO}_4 \cdot \text{H}_2\text{O}$, but there are no clear indications of the existence of other hydrates. The refractive indices, the constants of Cauchy's dispersion formula, and the Lorentz factor, all show irregularities between 92 and 100 per cent., consistent among themselves, and with a maximum density about 97 per cent. and a minimum point between 99 and 100 per cent. On this ground the authors doubt the existence of the substance represented by the simple formula H_2SO_4 .—J. T. D.

Sulphuretted Hydrogen and Arsenic Pentoxide; Interaction of — in presence of Hydrochloric Acid. F. L. Usher and M. W. Travers. Chem. Soc., Trans., 1905, 87, 1370—1373.

IN the purification of commercial hydrochloric acid by treatment with sulphuretted hydrogen, the arsenic present in the trivalent condition is immediately and completely precipitated, but that present in the quinquevalent condition separates slowly and is precipitated sometimes as arsenic pentasulphide, sometimes as the trisulphide mixed with sulphur. Experiments at 15° C. with hydrochloric acid of different strengths, but containing in every case 0.3664 per cent. of arsenic pentoxide gave the following results:—

Hydrogen Chloride. Per cent.	Composition of Precipitate.
1.8	As_2S_5 , 91 per cent.
7.9	As_2S_5 pure.
10.76	As_2S_5 pure.
14.34	As_2S_5 pure.
25.10	As_2S_5 , 58 per cent.
32.27	As_2S_5 pure.

It was found that the effect of the presence of hydrochloric acid in the reaction between arsenic acid and sulphuretted hydrogen is due to its influence on the arsenic acid. The rate of reduction of a solution containing 0.684 per cent. of arsenic pentoxide by a solution of sulphur dioxide in presence of varying concentrations of hydrochloric acid is shown in the following table:—

Sulphur Dioxide.	Hydrogen Chloride.	Result.
Per cent.	Per cent.	
3.272	4.9	Complete reduction in 45 secs.
3.272	20.3	28.3% reduced in 45 secs.
3.272	32.0	Complete reduction in 45 secs.

IN the reaction between arsenic acid and either sulphuretted hydrogen or sulphur dioxide in presence of con-

centrated hydrochloric acid, the first change is probably that expressed by the equation:—

further instantaneous reactions then taking place involving the formation of arsenic trisulphide and sulphur from the sulphuretted hydrogen. As the concentration of the hydrochloric acid increases, the condition of equilibrium expressed by the equation is rapidly displaced to the right. —A. S.

Vanadium Compounds; Some — [and the Detection of Hydrochloric Acid]. C. Matignon. Chem.-Zeit., 1905, 29, 986—987.

IN the decomposition of ammonium metavanadate (NH_4VO_3) by heat, any reduction of the resulting vanadic anhydride may be avoided by proper working. The pure salt should be roasted in an oxidising muffle with slowly-rising temperature, and care exercised to prevent melting until the decomposition of the ammonium salt is complete. A platinum dish must be employed, since silicates are attacked and iron causes reduction. In the above decomposition an intermediate product may be isolated. By slow heating of a thin layer, the colour is seen to pass through yellow, brown, ruby-red, and a metallic steel-blue, and finally to become brick-red. The metallic-looking body proved on analysis to have the formula $5\text{V}_2\text{O}_5 \cdot 2\text{VO}_3 \cdot \text{NH}_4$.

A paper soaked in ammonium metavanadate solution is coloured yellow immediately by a trace of hydrochloric acid, an acid vanadate being formed. This test may be used for the detection of hydrochloric acid.—F. SPS.

Carbon Dioxide; Disintegration of Iridium in —, and Dissociation of the Gas. F. Emich. Monatsh. f. Chemie, 1905, 26, 1011—1020.

THE author has attempted to utilise the disintegration of iridium by oxygen at high temperatures (see this J., 1902, 1332; 1903, 633) for the purpose of determining the degree of dissociation of carbon dioxide at high temperatures. Thin strips of iridium were heated by an electric current to temperatures measured by a Holborn and Kurlbaum optical pyrometer, in a current of carbon dioxide, comparative experiments being made in mixtures of nitrogen with oxygen, the proportion of oxygen being varied till the loss of weight of the iridium during a given time in the carbon dioxide was the same as that in the mixture, or lay between those in two neighbouring mixtures. The proportion of free oxygen in the carbon dioxide was then assumed to be the same as that in the mixture of equal disintegrating power, and the percentage dissociation calculated from that. Check experiments showed that the disintegration caused by nitrogen or carbon monoxide was negligible. The results as yet obtained are as follows, the corresponding figures calculated by Le Chatelier in 1888 and by Trevor and Kortwright in 1894 being given for comparison:—

Temperature °C.	Percentage dissociation.		
	Emich.	Le Chatelier.	T. & K.
1500	about 0.1	0.8	1
1970	4.5	4.0	8
2150	10—11	9.0	14

Sulphur [from Spent Oxide, &c.]; Extraction and Purification of —. A. V. Cornillaux, Deville, France. Eng. Pat. 7616, April 10, 1905.

THE spent material, which has been used for the removal of sulphur from coal gas, is treated with carbon bisulphide, which extracts the sulphur along with some tarry matters, and the resultant solution is then passed through a bed of acidulated coke or coke dust, which absorbs the tarry matters. On evaporation of the bisulphide solution, the sulphur obtained is yellow and of saleable quality. Preferably coke, the hydrocarbons of which are not exhausted (such as that coming from metallurgical workshops) is employed, and it may either be acidulated with 2–10 per cent. of concentrated sulphuric acid, or not acidulated.—H. B.

Alkali and Alkaline-Earth Metal Hydrides; Process of Producing —. F. J. Machalske, Brooklyn, N.Y., Assignor to F. Darlington, Great Barrington, Mass. U.S. Pat. 800,380, Sept. 26, 1905.

A COMPOUND of an alkali, or of an alkaline-earth metal, is electrically heated to a high temperature, and is then acted upon by a saturated hydrocarbon, such as methane (marsh gas) for instance, to produce the hydride. (Compare U.S. Pats. 742,340 and 745,637 of 1903; this J., 1903, 1298, and 1904, 21.)—E. S.

Sulphur; Process of and Apparatus for Mining —. H. Frasch, New York. U.S. Pats. 799,642 and 800,127, Sept. 19, 1905.

THE invention relates to a process of mining sulphur from porous rock, and consists essentially in melting the sulphur in the deposit and forcing it up to the surface of the ground by pressure. Water is heated to a temperature above that at which molten sulphur begins to darken, by bringing it in contact with high-pressure steam, and is then, together with the water of condensation, forced by steam pressure through two concentric pipes into the deposit. The outer pipe opens near the upper part of the mine cavity, whilst the inner one is closed at the bottom, but has a discharge outlet, a little above its closed end, opening near the lower part of the mine cavity. The hot water melts the sulphur and passes away through the porous rock, means being provided to prevent its return to the surface of the ground. The molten sulphur separates by gravity from the water, and is forced, by the steam pressure, up through an inner pipe which passes down through the closed end of the smaller hot-water pipe, and is provided at its lower end with a strainer. The hot water entering the mine cavity is kept under a steam pressure less than that of a column of molten sulphur, equal to the depth of the deposit below the level of the ground, but compressed air or the like is forced through a pipe, provided at its discharge end with a perforated piece of a metal not corroded by molten sulphur, into the column of molten sulphur, whereby the density of the latter is reduced to near or below that of water, and the molten sulphur is then readily forced up to the surface of the ground by the available pressure in the mine cavity.—A. S.

FRENCH PATENTS.

Sulphuric Acid; Manufacture of —, with Production of Cupric Sulphate and Recovery of Nitrous Products as Nitric Acid. L. J. Ménard-Decz. Fr. Pat. 354,073, April 21, 1905.

THE pyrites kiln, of eupola form, and increasing in diameter downwards, is fed from the top with pyrites in lumps ("pyrite en roche"). The dust-collecting chambers are, relatively, of constricted size, and after passing through them, the gases enter a packed tower in which they are washed by a stream of sulphuric acid and cooled to a temperature not exceeding 500° C. Between the dust chambers and the washing tower, or after the latter, the products of the decomposition of sodium nitrate are introduced. From the washing tower, the gases are led to a second packed tower designed to effect the concentration of dilute sulphuric acid by the passage of the hot gases; the acid flows from one obstruction to another in a thin stream, and is received in a closed vessel, from which the vapours which continue to be emitted, are withdrawn. The gases, now charged with sulphuric acid and water vapours, are led through a series of cylinders, packed with copper turnings, or with an oxide copper ore, and the cupric sulphate solution formed is collected for crystallisation. From these cylinders the gases pass to any ordinary system of lead chambers. The residual nitrous gases, instead of being led through a Gay-Lussac tower, for absorption by sulphuric acid, are treated in packed cylinders, such as those used in prior stages of the process, with air and water, for direct recovery of nitric acid.—E. S.

Hydrocyanic Acid; Manufacture of —. H. C. Woltereck. Fr. Pat. 354,081, May 5, 1905.

A GAS-GENERATOR filled with wood charcoal, is lit at the grate, below which air is continuously admitted; as the heat increases, ammonia gas is introduced in a zone sufficiently hot to reduce (in presence of carbon) carbon dioxide to the monoxide, and to decompose the water formed by the reaction ($\text{NH}_3 + \text{CO} = \text{HCN} + \text{H}_2\text{O}$), since in the presence of carbon dioxide or of water vapour, other nitrogenous compounds than the hydrocyanic acid desired, are liable to be formed. The hydrocyanic acid produced may be absorbed by, for instance, a caustic alkaline solution (See also Eng. Pat. 19,804, of Sept. 10, 1902; this J. 1903, 1129.)—E. S.

Sulphur and Cyanides from Spent Oxide, &c. : Process and Apparatus for the Extraction of — J. J. M. Bécigneul. First Addition, dated April 26, 1905, to Fr. Pat. 345,071, July 23, 1901. (See this J., 1904, 1216.)

INSTEAD of the toluene specified in the principal patent, a mixture of toluene and carbon tetrachloride, which is practically non-inflammable, is employed for the extraction of the sulphur. The hot solvent, at about 105° C., is admitted into the vessel containing the spent oxide, from below, through the false bottom; and the solvent, containing the sulphur and tarry matter, is treated with carbon (coke, charcoal, carbonised tar, &c.) in a jacketed tank provided with an agitator, until all the tarry matter has been absorbed. The hot, filtered solvent is then passed through inclined pipes enclosed in a cooling tank, the precipitated sulphur being retained by a filter, through which the solvent passes on its way to the receiver. The upper parts of all the vessels in the apparatus are connected by means of pipes, to equalise the pressure throughout.

—H. B.

Sulphur; Process for Extracting and Purifying the — contained in Materials which have been used for Purifying Illuminating Gas. A. V. Cornillaux. Fr. Pat. 353,932, March 25, 1905.

Sulphur; Sublimation of — E. L. Lalbin. Fr. Pat. 353,830, May 1, 1905.

THE invention consists in subliming free sulphur from sulphuretted ores or earths in a furnace or chamber by means of products of combustion furnishing a neutral, or slightly reducing flame. The ore is delivered into the top of a vertical tower or furnace, into the sides of which tuyères pass, conveying fire-gases from a neighbouring gas-producer or furnace, and air, in proportions to give the conditions necessary for heating the ores and subliming the sulphur. Powdered ores are treated in a slowly revolving horizontal chamber, under similar conditions adapted to the case. If required, combustibles, such as oil or the like, may be added to the ores, the air admitted being suitably adjusted for burning the same. (Compare Fr. Pat. 333,094 of 1903; and First Addition thereto; this J., 1903, 1292, and 1904, 62.)—E. S.

VIII.—GLASS, POTTERY, AND ENAMELS.

Glass; Physical Properties of — in Relation to Chemical Composition. E. Zschimmer. Z. Elektrochem., 1905, 11, 629—638.

IN a review of the successful production of new glasses for various technical purposes by Schott, the author gives the results of the hitherto unpublished researches of Schott and Abbe into the connection between the

refractivity of a glass and its chemical composition. By treating certain series of glasses as solutions of metallic oxides in vitreous silica, boron trioxide, and alkali silicate, curves are obtained which show (1) that the addition of metallic oxides to these solvents raises the refractivity, roughly in the order of the molecular weights of the oxides; (2) that the optical effect of lithium oxide upon boron trioxide, sodium oxide upon silica, and zinc oxide upon boron trioxide or alkali silicate decreases relatively with increasing concentration; and (3) that the effect of heavy oxides, such as baryta and lead oxide, increases relatively as the concentration increases. The optical effect of boron trioxide upon vitreous potassium silicate reaches a maximum at about 15 per cent., then decreases, and eventually proceeds in a negative direction.

Attention is drawn to the recent researches towards producing glasses having selective transparencies towards certain parts of the spectrum. The author's own U V glass, which transmits ultraviolet rays relatively very well, and is useful for stellar photography and for applications of the mercury vapour lamp, is now being improved upon in the direction of selective transmission of definite lines of the mercury spectrum by special glasses.

ENGLISH PATENTS.

Wood; Treatment of — for Rendering it Fireproof. W. H. Perkin, jun., and Whipp Bros. and Todd, Ltd., Manchester. Eng. Pat. 22,169, Oct. 14, 1904.

THE process consists in treating wood so as to cause, within its pores, interaction between a salt, especially sodium stannate, containing in its acid radical the oxide of a metal and a salt not containing such metallic oxide in its acid radical, or an ammonium salt, with or without addition of ammonia or an organic acid. For example, the wood is treated in a closed vessel for six hours under a pressure of 500 lb. per sq. in. with a solution of sodium stannate of 32° B., or a mixture of 2 parts of sodium stannate solution of 11° B. and 3 parts of sodium tungstate solution of 32° B., or with a solution of sodium arseniate of 18° B. After draining, the wood is dried by hot air, and may then be further treated under pressure with a solution of ammonium sulphate of 11° B., or a solution of zinc acetate or sulphate of 17° B., or with a mixture of 1 part of the zinc solution and 1 part of tartar emetic solution of 6° B. The wood is now again allowed to drain, and is then dried, after which it may be used, or it may be washed with water and again dried before being used.—A. S.

Stone; The Colouring of [and Producing Grain in] — H. H. Lake, London. From Chem.-Technische Fabrik, Dr. A. R. W. Brand und Co., G.m.b.H., Charlottenburg, Germany. Eng. Pat. 23,292, Oct. 28, 1904.

Furnace; Clay-Treating — D. B. Williams, Assignor to J. R. Stauffer, both of Scottsdale, Pa. U.S. Pat. 799,127, Sept. 12, 1905.

THE furnace comprises an upright covered furnace casing

provided with a fixed interior chamber of lesser height and width. This interior charge-chamber is open at the top and is provided with a side test-opening at the bottom and with bracing webs in the space between it and the furnace walls. Supporting arches adjoin the bottom of the charge-chamber, being spaced apart to provide intervening fuel-spaces in communication with the fuel-space at the sides of the charge-chamber. The furnace casing is provided with a blast-connection at its bottom. —A. G. L.

X.—METALLURGY.

Steels; Thermal Transformations of Carbon ——. J. O. Arnold and A. McWilliam. Iron and Steel Institute, Sept. 1905. [Advance Proof.]

THE general summary of the authors' results is as follows: —*Unsaturated Steel* (0.21 per cent. of carbon). 1. On cooling from 950° C., the hardenite and ferrite remain in mutual solution as a homogeneous mass till Ar_3 is reached (about 810° C.), when segregation of the two constituents begins. This segregation, if the cooling be slow, is probably completed in the β range of temperature; so that in both the α and β ranges of temperature hardenite is insoluble in ferrite. The hardenite remains as such from the end of Ar_3 , about 720° C., to the beginning of Ar_1 , about 680° C., below which temperature it begins to decompose into pearlite. 2. On heating from a low temperature, pearlite at Ac_1 , about 710° C., begins to change into hardenite (so that the B carbide of pearlite is soluble in ferrite in the α range). At 720° C., when Ac_1 merges into Ac_2 , the change to hardenite is far advanced, and the hardenite occupies the space formerly occupied by the pearlite, up to Ac_3 (about 810° C.) when the hardenite and ferrite begin mutually to dissolve, and ultimately form a homogeneous substance. *Saturated Steel* (0.89 per cent. of carbon). 1. On cooling, much heat is evolved at the single point $Ar_{1,2,3}$ (690°—680° C.), marking the transformation of hardenite into pearlite. According as the cooling from 660° C. to the ordinary temperature is very rapid, ordinary, or very slow, the pearlite contains the carbide in a very finely divided or "emulsified" state, is normal, or laminated. "Emulsified" pearlite may also be obtained by tempering hardenite. Osmond has called it "sorbite," but the authors claim that it is simply pearlite. 2. On heating, an absorption of heat occurs at $Ac_{1,2,3}$ (710°—730° C.), when the pearlite changes into hardenite. *Supersaturated Steel* (1.78 per cent. of carbon). On cooling, cementite begins to separate out at about 900° C., with slight evolution of heat, and is completely segregated long before the point $Ar_{1,2,3}$ is reached. On heating, the pearlite changes to hardenite at $Ac_{1,2,3}$, the cementite gradually segregates into larger masses, and above 900° C. the cementite and hardenite mutually dissolve to a homogeneous substance. The transformations of cementite and hardenite seem to have no connection with any of the three critical points, but to be influenced only by temperature. *Pure Iron*.—Test-pieces of pure iron were heated in nitrogen to 990° C., and then quenched from various temperatures in iced brine. The ductility was found to be practically unaltered, whatever the quenching temperature. The tenacity is unaltered up to a quenching temperature of 500° C., and between that temperature and 900° C., it is proportional to the excess of temperature above 500° C. The transformations at Ar_3 and Ar_2 seem to be absolutely without influence on the mechanical properties of the iron.

The authors consider that the carbide Fe_3C of pearlite is not identical with the carbide of the same composition contained in cementite, and propose to distinguish them as the B and A carbides respectively. Their reasons for this are, first, that the B carbide dissolves in iron in the α range of temperature, while the A carbide does not, but dissolves only in the β range; second, that the A carbide is strongly electronegative to the B carbide.

The question of the transformation of cementite into ferrite and amorphous graphite is also touched on, the authors putting forward tentatively the view that in the

slow cooling of a supersaturated steel from 1100° C., the dissolved cementite separates completely at 900° C., and then gradually segregates into nodules. After the $Ar_{1,2,3}$ change, the pearlite separates and becomes laminated, then the carbide of the cementite attracts to it the carbide of the pearlite, over a certain range, leaving the ferrite of the pearlite. Below a red heat the joint carbides dissociate into graphite and ferrite, the graphite occupying the space formerly filled by the carbide masses, and the ferrite adding itself to that arising from the decomposition of the pearlite.

The work is illustrated by many photomicrographs, and includes an appendix defining the terms used, and describing the various constituents of iron-carbon alloys.

—J. T. D.

Steel; Elastic Properties of —, at High Temperatures. B. Hopkinson and F. Rogers. Proc. Roy. Soc., 1905, 76. A. 419—245.

A SMALL test-piece was heated in an electric furnace to temperatures ranging up to 800° C. in a non-oxidising atmosphere, and stresses far below the elastic limit were applied for periods of a minute, with intervals of rest of two minutes between each two successive applications of the stress. The curves of stress show that after the instantaneous elongation, the metal is overstrained and continues slowly to elongate, while on removing the stress the instantaneous contraction is followed by a slow additional contraction or recovery, though some permanent strain remains. The amount of permanent set produced by each loading is less than that produced by the preceding loading, showing that the metal hardens under the process. With iron, the same phenomena were observed as with steel containing 0.5 per cent. of carbon, but the metal flowed at a lower stress; and with both bars the effect at 600° C. was much less than at 750° C., the permanent extension being practically zero. The slow creep in the steel bar at 600° C. amounted to about 15 per cent. of the total deformation.

When the period of application of the stress was much diminished, the observed strain approached a limit; and taking Young's modulus as the quotient of the stress by this limiting instantaneous strain, the authors find that approximately, within the limits of experimental error, the value of Young's modulus for both iron and steel is about 0.6 at 600° C., and about 0.5 at 750° C., the value in the cold being taken as unity.—J. T. D.

Iron; Influence of Nickel and Carbon on —. G. B. Waterhouse. Iron and Steel Inst., Sept., 1905. [Advance Proof.]

THE author's experiments were made with a series of nine ingots of nickel steel containing a practically constant amount (about 3.5 per cent.) of nickel, with percentages of carbon varying from 0.40 to about 1.60 per cent. The ingots were prepared from puddled bar iron ("muck bar"), wood charcoal and pure electrolytically-deposited nickel. The ingots were analysed, tested mechanically after various heat treatments, and examined micrographically. The heating and cooling curves were also determined. *Heat Treatment*. A.—Test-bars, 12 in. long, were heated to 1000° C. in a gas-fired muffle-furnace in the course of 1 hour and 25 minutes, and kept at this temperature for 25 minutes, after which they were cooled in air, the object being to re-crystallise the steels, and to remove any distortion or strain produced during rolling. B.—The bars were placed in an annealing furnace at 500° C., and heated to 870°—880° C. in the course of 5½ hours. After a further three hours at this temperature, they were allowed to cool slowly in a pit, the wrought iron tube containing them being covered with ashes. The results show that nickel causes a distinct increase in the tenacity of the steel, without materially lowering the ductility. The elastic ratio or the ratio of the elastic limit to the ultimate strength is only slightly greater in pure nickel steels than in carbon steels. The high elastic ratio of commercial nickel steels is probably due to the large amount of manganese present. On annealing nickel steels, the tenacity is markedly reduced, whilst the ductility is not greatly increased. Steels with low percentages of

nickel contain, in the unquenched state, ferrite, pearlite, cementite, and graphitic carbon; the pearlite readily segregates into ferrite and cementite, the latter having the composition $\text{Fe}(\text{Ni})_3\text{C}$. The eutectoid ratio in the steels examined appears to lie at about 0.7 per cent. of carbon, but in the rolled steels, no free cementite appeared until the amount of carbon reached about 1.0 per cent. The transformation-points $\text{Ar}_{3.2}$ and Ar_1 were lowered about 20°C . for every 1 per cent. of nickel. It was observed that the cementite showed considerable tendency to separate as "temper graphite." A bibliography is appended to the paper.—A. S.

Steel; Overheated — A. W. Richards and J. E. Stead. Iron and Steel Inst., Sept., 1905. [Advance Proof.]

AFTER reviewing the opinions of those who have specially studied the question, the authors give the following definitions to prevent the confusion which appears to have arisen from confounding "burnt" with "overheated" steel. Overheating is heating at any point below that which produces incipient disintegration and results in the formation of large crystals.

Burning is heating at or above the point at which

especially in places where the martensite is in contact with ferrite or cementite. In distinguishing between troostite and sorbite, the author states that troostite is found when the martensite or austenite has already begun to undergo transformation which ultimately results in pearlite, whilst sorbite occurs when the martensite has not been completely resolved into pearlite. In other words troostite is the first, sorbite the last stage of transformation between martensite and pearlite. For example, if the bulk of a section of the metal is composed of martensite (+austenite), but certain parts become dark on etching, these are called troostite; if the bulk is composed of pearlite, the parts which become dark on etching are called sorbite.—A. S.

Irons; Note on the Occurrence of Copper, Cobalt, and Nickel in American Pig — E. D. Campbell. Iron and Steel Inst., Sept., 1905. [Advance Proof.]

THE author determined the copper, cobalt, and nickel in a number of samples of pig iron procured from charcoal or coke blast-furnaces in various parts of North America, especially in the United States. The results are shown in the following table:—

No.	Kind of ore.	Source of ore.	Fuel used.	Copper. Per cent.	Cobalt. Per cent.	Nickel. Per cent.
1	Mixed limonite, carbonate and hematite	Nova Scotia	Coke	0.011	0.012	0.015
2	Local hematites	Mexico	Charcoal	0.012	0.009	0.006
3	† Mesabi; † Vermilion Range	Minnesota	Coke	nil	nil	nil
4	Gogebic hematite	Wisconsin	Charcoal	nil	nil	nil
5	Magnetic concentrates	New York	Charcoal	0.039	trace	trace
6	Salisbury brown hematite	Connecticut	Charcoal	0.018	0.029	trace
7	† Local hematite; † magnetite	Virginia	Coke	0.169	trace	0.009
8	Local brown hematite	Alabama	Charcoal	0.038	0.048	0.072
9	Native hematite and magnetite	Colorado	Coke	0.039	nil	nil

such disintegration occurs; burnt steel is nearly always coarsely crystalline. The authors believe that burnt steel cannot be completely restored by reheating, but after making a large series of experiments, the details of which are fully recorded, they conclude that overheating reduces the power of the steel to resist fatigue; that reheating such steel more than restores the original good qualities of the rolled bars; and that when the steel has its carbon in the sorbitic condition, its power of endurance is more than doubled. In giving certain "hypothetical conclusions," the authors remark that it would be an ideal condition if free ferrite were absent from carburised steels which are to be subjected to severe vibratory stresses. They also desire to emphasize the fact that they do not maintain that steel, initially bad, brittle, and dangerous, can be made good by any kind of heat treatment (short of fusion).—J. H. C.

Steel used for Motor-Car Construction in France. L. Guillet. Iron and Steel Inst., Sept., 1905 [Advance Proof.]

THE chief steels used are:—Ternary: nickel steels, chrome steels, silicon steels (so-called silico-manganese steels), and tungsten-steels. Quaternary:—chrome-nickel steels, and other steels of unknown composition.

The composition, characters and uses of many varieties of these steels are described and discussed.

—J. H. C.

Troostite; Nature of — C. Benedicks. Iron and Steel Inst., Sept., 1905. [Advance Proof.]

THE author discusses the nature of troostite, more especially with a view to refute the recent conclusions of Boynton (this J. 1904, 608) and Kourbatoff (1904, 1149; 1905, 621). He concludes that Osmond's conception of troostite as an intermediate form between martensite and pearlite is correct. There is a continuous transition between troostite and pearlite, and the former must be regarded as a pearlite with ultra-microscopically small particles of cementite (containing also more or less hardening carbon). It is probable that troostite is formed by a transformation *in situ* of martensite; it is produced by suitable lessening of the intensity of the hardening,

It is noteworthy that samples No. 6 and 8, which are the only ones containing any considerable amount of cobalt or nickel, are stated to have gained a reputation for their valuable properties for car-wheel castings. A. S.

Vanadium; Use of — in Metallurgy. L. Guillet. Iron and Steel Inst., Sept., 1905. [Advance Proof.]

THE preparation, characters, treatment and uses of ferro-vanadium, vanadium steels (normal, quenched and forged), nickel-vanadium steels, manganese-vanadium steels, chromium-vanadium steels, silicon-vanadium steels and tungsten-vanadium steels; as also of copper-vanadium bronzes, alloys of aluminium and vanadium, and certain other vanadium alloys are described and discussed, and the author reaches the following conclusions:—

1. On normal steels vanadium produces a very distinct increase in the tensile strength and elastic limit, and has no influence, or an insignificant one only, on elongation and contraction and upon resistance to shock. It slightly increases the hardness.

2. On quenched steels, vanadium considerably increases the tensile strength and elastic limit; it acts in this way with almost as great an effect as carbon, yet, notwithstanding this, it does not increase the brittleness.—J. H. C.

Nickel; Apparatus for Obtaining — from Nickel Carbonyl. C. Langer, Ynyspenllwch, Glamorgan, S. Wales. Eng. Pat. 13,350, June 28, 1905.

THE vessels containing the nickel carbonyl (see Eng. Pat. 1106 of 1898; this J., 1899, 49) are heated by a number of gas flames, each of which is situated in a chamber formed by ribs on the vessel and the outer casing; the liberated gases pass away by an escape pipe, which is surrounded by an annular cooling chamber.—J. H. C.

Silver Alloys; Impts. in —. A. E. Hobson, New Haven, Conn., U.S.A. Eng. Pat. 13,613, July 3, 1905.

THE alloy is composed of silver and manganese with or without small proportions of copper or zinc, the silver being not less than 925/1000ths of the whole.—J. H. C.

UNITED STATES PATENTS

Iron Sponge; Producing Wrought —. D. Reynolds, Albany, N.Y. U.S. Pat. 799,189, Sept. 12, 1905.

GRANULATED oxide of iron, mixed with carbonaceous material in sufficient quantity is placed within a suitable movable furnace, the inner walls of which have been previously sufficiently heated to deoxidise and carburise the iron. The furnace is then closed and the mixture is agitated until the required sponge is produced.—J. H. C.

Gold; Process of Extracting — from its Ores. F. W. Dupré, Leopoldshall, Germany. U.S. Pat. 799,548, Sept. 12, 1905.

SEE Ger. Pat. 160,738 of 1904; this J., 1905, 894.—T. F.B.

Ores; Treatment of Sulphide and Complex —. C. H. Ward, Sydney, N.S.W. U.S. Pat. 799,696, Sept. 19, 1905.

CRUSHED sulphide ores are roasted, with access of air and water, by passing them through a current of gases, heated to a temperature sufficient to cause the decomposition of the sulphides, and moving in a direction opposite to the movement of the ore. The ore is then mixed with a substance containing chlorine, such as sodium chloride, and subjected to the action of the hot gases produced in the first stage of the process. In this latter stage of the process the ore and hot gases are caused to move together in the same direction, and the temperature is reduced by the introduction of a cooling medium, such as air or water.—A. S.

Zinc Ores; Process of Treating —. P. A. Mackay, Wenona, Ill. U.S. Pat. 799,743, Sept. 19, 1905.

SULPHIDE ores containing cadmium and zinc are subjected to a "dead" roast, whereby the zinc is converted into oxide and the cadmium into sulphate. The product is treated with water to remove the cadmium sulphate, and is then ground and distilled to recover the zinc.—A. S.

Nickel; Process of Separating — from Mattes. R. H. Aiken, Winthrop Harbour, Ill. U.S. Pat. 800,130, Sept. 26, 1905.

NICKEL-COPPER sulphide mattes are heated in a converter to a temperature between 800° and 1700° C., treated with a suitable quantity of a highly-heated flux, containing at least 70 per cent. of silica, and the mixture subjected to an oxidising blast. The amount of flux added at first is only sufficient to slag the iron; after removing the iron silicate slag, a further quantity of flux is added, and the mixture again "blown." The nickel silicate slag produced is removed before the blast has acted appreciably on the copper.—A. S.

Furnace; Roasting —. F. Klepetko, New York. U.S. Pat. 799,063, Sept. 12, 1905.

THE furnace consists of a hollow rabble-shaft divided

into a series of contiguous compartments having structural members radiating from the shaft and forming portions of the division walls between the compartments, with suitable complementary formations located within the shaft for completing said division walls. Hollow arms are provided, passing over said members and forming conduits therewith, these arms establishing communication between two consecutive compartments through the conduits.—J. H. C.

Furnace; Roasting —. A. R. Meyer, Assignor to The United Zinc and Chemical Co., both of Kansas City, Mo. U.S. Pat. 800,588, Sept. 26, 1905.

THE furnace has side and end walls of masonry, with external buttresses at opposite sides, connected by cross-beams. A number of arches, one above the other, extend from end to end of the furnace, and a series of hearths are formed above each arch. Below the hearth-arches are other arches, each of which forms with the hearth-arch above a heating flue; these flues are connected in series. The furnace is also provided with a number of shafts carrying rabblers which pass over the different hearths.—A. S.

Furnace; Metallurgical —. P. A. Mackay, Newcastle, N.S.W. U.S. Pat. 799,745, Sept. 19, 1905.

THE plant claimed has parallel passages or chambers extending longitudinally along its middle and regenerative furnaces extending longitudinally along its sides, with passage ways between the furnaces and chambers. Between the chambers are hollow partitions forming reduction chambers, which communicate by passage-ways with oxidising chambers extending longitudinally over the regenerative furnaces. Each reduction chamber has an opening in its top for the introduction of the material to be treated, and a trap-door in its bottom, through which the treated product is conveyed to a passage-way below.—A. S.

Furnace. M. Leitch, Brooklyn, N.Y. Assignor to Sheet Metal Recovery Co., New Jersey. U.S. Pat. 800,222, Sept. 26, 1905.

THE furnace is intended for the separation of materials melting at different temperatures. It consists of a chamber provided with a sealed inlet and with a discharge outlet dipping into a liquid seal. A centrifugal separating receptacle is mounted in the chamber on a central shaft, which also carries a feeding hopper projecting downwards into the separator and provided on its inner surface with a spiral groove forming, with a similar groove on the shaft, a conveyor by which the material fed into the receptacle is moved forwards to the discharge opening. A "deoxidised atmosphere" having a temperature sufficiently high to melt the more easily fusible constituent of the material under treatment is maintained in the chamber; the melted material is thrown off by the centrifugal force, whilst the unmelted portion is continuously discharged through the sealed outlet of the chamber.—A. S.

Tin Scrap; Treating —. M. Leitch, Brooklyn, N.Y. U.S. Pat. 800,223, Sept. 26, 1905.

THE process relates to the preliminary treatment of tin scrap from which the tin is subsequently recovered by a de-tinning bath. The scrap is heated, for example, in an apparatus such as that described in the preceding abstract, in a "deoxidised atmosphere" to a temperature insufficient to melt the tin, but sufficient to volatilise the volatile matter and carbonise the carbonaceous matter of the "filth" adhering to the scrap. The heated material is subjected to centrifugal force, and to mechanical blows to separate the carbonised matter.—A. S.

Zinc Ores; Treatment of —. E. Demenge. First Addition, dated April 22, 1905, to Fr. Pat. 348,733, Dec. 9, 1904 (this J., 1905, 549).

ACCORDING to the present Addition, the furnace described in the main patent is provided with several rows of tuyères, to ensure that the whole of the zinc is converted into oxide or carbonate.—A. S.

Autoclave for Continuous Saponification and other Purposes [Application to the Treatment of Tin ores]. L. Rivière. Addition, dated April 28, 1905, to Fr. Pat. 352,182, March 8, 1905 (this J., 1905, 933).

SPECIAL claim is made for the use of autoclaves of this type in the continuous treatment of tin ores, and notably sands rich in tin and sometimes containing gold. The mineral is disintegrated by being made to circulate through the autoclave at varying pressures in contact with strong caustic soda lye, which brings the tin into solution and effects the separation of iron oxide and of gold when present. The sodium stannate is decomposed by treatment with an acid, and the resulting sodium salt reconverted into hydroxide by the action of lime in an autoclave. The oxide of tin is reduced by the usual methods.—C. A. M.

Copper and its Alloys; Process for Extracting and Refining — contained in Ashes, Sand, and Foundry or other Refuse. C. Casman. Fr. Pat. 353,784, April 28, 1905. Under Int. Conv., May 7, 1904.

Crucibles or Receivers; Method of Making — for Metallurgical Use. A. L. J. Queneau. Fr. Pat. 354,319, May 16, 1905. Under Int. Conv., May 21, 1904.

THE principal body of the crucibles or receivers is formed of a mixture of refractory clay and sand; linings of refractory clay mixed with a substance capable of resisting the chemical operations concerned are placed inside or outside this; in addition thin linings of clay alone are sometimes interposed or superposed, and the whole is firmly compressed before baking.—J. H. C.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(A.)—ELECTRO-CHEMISTRY.

Nitrates of Potassium, Sodium and Lithium; Electrolysis of — in the Fused Condition. A. Bogorodski. J. russ. phys.-chem. Ges., 1905, 37, 703–759. Chem. Centr., 1905, 2, 954–955.

THE fused nitrates of potassium, sodium and lithium were separately electrolysed at temperatures near their melting points in U-shaped tubes, and the gaseous decomposition products and the portions of the electrolyte surrounding the anode and cathode were analysed. A platinum anode was used with an aluminium or graphite cathode. The gases evolved at the anode consisted exclusively of oxygen and nitrogen peroxide, whilst the aqueous solutions of the electrolyte were found to contain the nitrite and oxide of the metal. During the electrolysis of potassium and sodium nitrates with currents of from 5 to 35 volts, the electrolyte became bright yellow to orange-red in the neighbourhood of the cathode, with separation of yellow precipitates which redissolved in the surrounding liquid. These coloured precipitates are probably higher peroxides of the metals. Fused lithium nitrate on electrolysis remained colourless near the cathode, but became orange-coloured at the anode. With an E.M.F. of more than 6 volts, the separation of metallic lithium at the cathode was observed. Analysis of the gases evolved at the anode gave results corresponding to the equation: $\text{KNO}_3 = \text{K} + \text{NO}_2 + \text{O}$, but the ratio of alkali oxide to nitrite in the cathode-liquid varied according to the cathode employed, as is shown in the following table:—

	Graphite cathode.	Aluminium cathode.
$\text{K}_2\text{O} : \text{KNO}_2$	1:2.0	1:1.0
$\text{Na}_2\text{O} : \text{NaNO}_2$	1:1.6	1:0.8
$\text{Li}_2\text{O} : \text{LiNO}_2$	1:1.0	1:1.0

The author considers that when graphite cathodes are used in the electrolysis of potassium nitrate, the potassium separated is oxidised by the electrolyte to KO, which latter then reacts with the carbon of the cathode, according to the equations:

With aluminium cathodes only the process represented by the first equation takes place. Under the same conditions, lithium appears to be oxidised only to the oxide Li_2O . When aluminium cathodes are employed in the electrolysis of sodium nitrate or potassium nitrate, it is probable that the metal separated is partially oxidised to higher peroxides. This view finds confirmation in the fact that if, after electrolysis, the melt be dissolved in water, oxygen is evolved.—A. S.

Accumulators; Process for Regenerating Electric —. C. Luckow, Cologne. Eng. Pat. 11,353, May 30, 1905.

THE electrodes to be regenerated are immersed in an electrolyte consisting of a very dilute solution of a metallic salt, preferably one containing 1 to 3 per cent. of sulphate, carbonate, or borate of potassium or sodium, or the hydroxides of these metals may be used. The current is passed in the opposite direction to a charge for four to eight days at 2 to 3 volts., and with a current density of 15 to 20 ampères per sq. m. of positive electrode, and the current then reversed for three to six days, when the regeneration is complete.—B. N.

Water or other Liquid; Extraction of — from Mineral, Vegetable, and Animal Substances. O. Imray, London. From Meister, Lucius and Brünig, Höchst a. Maine. Eng. Pat. 24,670, Nov. 14, 1904.

IMPROVEMENTS in the electro-osmotic process of extracting water or other liquids from materials, described in Eng. Pat. 22,301 of 1901 (this J., 1902, 1335) are claimed. The material is caused to travel either continuously or intermittently between two bands which may be either stationary or which may one or both move in the direction in which the material to be treated moves. The wires carrying the electric current may be attached to these bands if they are formed of conducting materials, or, if they are non-conductors, then the current is connected to electrodes placed behind the pervious bands, and which are caused either intermittently or continuously to touch them. The essential point of the improvement claimed is the prevention of any material alteration in the relative position of the component particles of the substance treated.—W. H. C.

Ozoniser; Rotatory —. M. Otto. Fr. Pat. 354,020, May 6, 1905.

THE fixed electrode of the apparatus, which is connected to the earth, consists of a vertical pipe provided on the outside with a series of horizontal ribs or flanges. Concentrically within this pipe are two tubes, the outer one of which has on its exterior a number of longitudinal ribs. A current of cold water passes up the innermost tube and then down through the annular space between it and the enclosing tube. The air or oxygen to be ozonised is forced up through the annular space between the outer pipe and the intermediate tube, escapes through perforations in the former, and is then led away through a conduit provided for the purpose. The rotating electrode consists of a series of hollow metal rings, encircling the perforations in the fixed electrode, and secured to arms mounted on three vertical insulated shafts, equidistant in a radial direction from the central perforated pipe, and connected to the source of current. These shafts are caused to travel in a circular path by means of a motor. The electric discharge is produced between the metal rings and the lateral surfaces of the horizontal flanges or ribs on the fixed electrode.—A. S.

Ozone; [Electrical] Generator of —. A. Bomsel. Fr. Pat. 354,331, May 16, 1905.

A LIQUID, acting as the dielectric, is circulated through the apparatus, and is continuously subjected to the action of the electric discharge. If necessary, contact of the liquid with the ozone may be avoided by the use of a light solid dielectric, such as stretched silk, placed on the surface of the liquid. Two forms of apparatus are described, in one of which a vertical sheet of liquid is delivered over a cylindrical electrode, whilst in the other the liquid forms a series of horizontal sheets, being delivered to one angle of a horizontal basin, and falling through a suitable opening, in the angle diametrically opposite to the angle of delivery, to the basin below.—B. N.

(B).—ELECTRO-METALLURGY.

UNITED STATES PATENT.

Furnace; Revolving Electric —. E. Stassano, Rome. U.S. Pat. 799,105, Sept. 12, 1905.

A CIRCULAR closed chamber, with its axis inclined at an angle to the vertical, is provided with means for rotation, and the two electrodes are connected to the pistons of two hydraulic cylinders, the latter having their ends connected by water pipes, so that the anode and cathode may be fed towards each other. The electrodes are enclosed within "double-walled carbon-holder casings," through which water is continuously circulating, the casings rotating together with the electrodes and the furnace. The casings communicate with a disc rotating on a stationary disc, the latter being fitted with grooves connected to the pipes of a water-pressure supply. Conductors are connected to the electrodes, the conductors ending in brushes sliding on two discs fixed to a stationary pipe.

forming a chimney, the discs being in connection with the electric supply. The chimney is in connection with the waste-gas passage of the chamber, and the pipe dips into an annular cup which is filled with sand or other finely pulverised heat-resisting material so as to form a seal at the joint, the cup being fixed to the rotating body of the furnace.—B. N.

Metal; [Electrolytic] Process of Depositing—on Non-metallic Bodies. C. F. Blackledge, Washington, D.C. U.S. Pat. 799,218, Sept. 12, 1905.

A MOULD of non-conducting material is prepared, and coated with a substance that will conduce to the precipitation of metallic silver. Ammonia is added to a solution of silver nitrate until the precipitate is redissolved, and formaldehyde added to the liquid, the mixture being then applied to the coated mould; a metal, such as nickel, is then deposited on the silver surface of the mould by electrolysis.—B. N.

Electro-plating Apparatus. L. Potthoff, Brooklyn, N.Y. U.S. Pat. 799,402, Sept. 12, 1905.

A TRAVELLING belt carries a series of hooks which form the cathode terminal for supporting the work in a horizontal position, and means are provided for moving the bars or rods to be coated with metal from one portion of the hook to another, in order to change the point of contact. An arrangement, for automatically discharging the bars from the belt after leaving the tank, is provided.—B. N.

Galvanising Wire; [Electrolytic] Process of—G. L. Meaker, Evanston, Ill., Assignor to The American Steel and Wire Co., of New Jersey. U.S. Pat. 799,869, Sept. 19, 1905.

THIS invention relates to a method of depositing zinc on a wire, and consists in continuously passing the latter as a cathode through a "ferriferous zinc solution" in the presence of a series of insoluble anode-sections. The latter have a greater surface area than the cathode in order to render the iron insoluble, and the solution is oxidised by aeration. The solution is regenerated by retaining therein the active dissolving agents, and by circulating it over a mass of zinc or zinc-bearing compound. A current density of at least 400 ampères per sq. ft. of cathode surface is used, and the current is conducted from the moving cathode wire at a series of connection points, so as to superpose on the deposit formed at the latter points, the deposit formed at intermediate parts by giving the wire an adequate speed of travel.—B. N.

Electrolytic Apparatus. G. L. Meaker, Evanston, Ill., Assignor to The American Steel and Wire Co. of New Jersey. U.S. Pat. 799,861, Sept. 19, 1905.

THIS invention consists of an electrolytic apparatus comprising a series of anode-sections of insoluble material, such as carbon, each provided with a number of channels to receive cathode wires dropped into them from above. Between the anode-sections is interposed a series of cathode contacts provided with yielding surfaces so as to permit of the passage of a joint in the wire. Each cathode-contact consists of a pocket or receiver of conducting material, open on one side to receive the wire and with slots on the opposite side, through which the wire may enter and leave the pocket. A number of loose balls is contained in the pocket, of a size larger than the openings for the wire. A series of independently-journalled sheaves is provided at each end of the apparatus, these corresponding to the number of anode channels, and in line therewith. Insulating guides, covering the anodes and having openings in line with the channels, prevent contact of the wires with the adjacent surfaces of the anode-sections. Metallic rods extend along the anodes, opposite and transverse to each of the channels, and connect a "bus-bar" to the anode-sections, an electric switch between each of the rods and the bus-bar acting as a regulating means to equalise the potential at each of the channels.—B. N.

Zinc Compounds; [Electrolytic] Process of Separating "Ferriferous"—G. L. Meaker, Evanston, Ill., Assignor to The American Steel and Wire Co. of New Jersey. U.S. Pat. 799,862, Sept. 19, 1905.

THIS invention relates to a process of separating "ferriferous" compounds of zinc, and consists in dissolving the compounds by circulating over them an acid solution, afterwards passing the solution through an electrolytic cell containing an insoluble anode adjacent to a moving cathode of smaller superficial area. The solution is oxidised, the iron being precipitated in an insoluble basic ferrous or ferric form, and the zinc is deposited on the cathode. A current density of at least 400 ampères per sq. ft. of cathode surface must be employed.—B. N.

Tantalum Metal; Process for Purifying—W. V. Bolton, Assignor to Siemens and Halske Akt.-Ges., Berlin. U.S. Pat. 799,141, Sept. 12, 1905.

Iron or Steel; Process of Cementing—C. C. Davis, Germantown, Pa. U.S. Pat. 799,542, Sept. 12, 1905.

THE articles are maintained at 800° to 850° C. while packed in contact with carbonaceous material between two metal plates, and a direct electric current of suitable strength and character is passed through them, from a common positive electrode placed between the plates. J H. C.

FRENCH PATENTS.

Furnace; Electro-Metallurgical—Soc. D'Exploitation des Brevets Dolter. Fr. Pat. 353,391, April 15, 1905.

THIS invention relates to an electro-metallurgical furnace shown in sectional elevation in Fig. 1 and in plan in Fig. 2. The metallic bath is composed of two channels *bb'* united together, the channels being concentric with, and at the same height as the bobbins of the primary *d* of a transformer, the bath of metal acting as the secondary. The

FIG. 1.

FIG. 2.

portion *bb'*, which connects the channels and which is adjacent to the tapping hole *c*, has a transverse section twice that of the other parts of *b* so as to increase, at this point, the fluidity of the metal. The transformer is made in two separate movable pieces, one portion *e*,

which carries the primary *d*, fitting into appropriate cavities in the stonework *a* of the furnace, and the other portion *f*, carried by a waggon *g*, completing the magnetic circuit. A single alternating monophasic transformer may thus be used to serve a series of such furnaces. —B. N.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

Sesamé Oils of Different Origin; Characteristics of — [and Detection of Sesamé-Oil in Butter]. H. Sprinkmeyer and H. Wagner. Z. Untersuch. Nahr. u.-Genußsm., 1905, 10, 347—353.

SAMPLES of Indian, Levant and African sesamé oil obtained by hot and cold expression were examined by the authors, but no material differences were observed in the chemical or physical values of the two first-named. The African oil, however, had a considerably higher iodine value, optical rotation and refractometer reading than the other two. Thus:—

Sesamé Oil (cold-drawn).	Iodine Value.	Rotation.
Indian	108.51	+ 1.03°
Levant	108.84	+ 1.11°
African	114.11	+ 1.42°

Similar differences were observed between the oils obtained by extraction of the press-cake with ether or petroleum spirit, and extraction of the original seeds with a solvent. The African seeds also gave a larger yield of oil on extraction, viz., 52.54 to 54.14 per cent., as against 47 to 49.76 per cent. for Indian seeds and 47.57 to 50.14 for Levant seeds. The following modification of Baudouin's test was found to be capable of detecting with certainty 0.1 per cent. of sesamé oil (corresponding to 1 per cent. of margarine) in butter fat:—50 to 100 grms. of the clarified and filtered butter fat are thoroughly shaken in a separatory funnel with 20 to 30 c.c. of glacial acetic acid, preferably at a temperature of 60° C. The acid extract is drawn off, and the extraction repeated with a fresh portion of acetic acid. The united extracts are evaporated on the water-bath, the residue saponified with 5 c.c. of a saturated solution of barium hydroxide and 10 c.c. of alcohol, and the soap dried on the water-bath. The dried mass is now powdered in a mortar and extracted several times with petroleum spirit, which dissolves the substance giving the characteristic coloration in the Baudouin reaction, whilst the dyestuffs added to butter and margarine are left in the insoluble residue. The united petroleum spirit extracts are filtered through a baryta filter and the colourless filtrate concentrated to 1 or 2 c.c. in a porcelain basin, and shaken in a narrow test tube with 1 c.c. of hydrochloric acid (sp. gr. 1.19) and 2 drops of a 1 per cent. solution of furalin in alcohol.—C. A. M.

Wheat Oil and Maize Oil. H. Snyder. Der Seifenfab., 1904. Z. Spiritusind., 1905, 28, 369.

THE wheat germ contains only 17.5 per cent. of oil, whereas the maize germ contains about 50 per cent. For the separation of the maize oil, the corn is steeped in water containing sulphurous acid, and is then crushed between fluted rolls. The elastic germ resists this treatment, whilst the starch of the endosperm is liberated. The separation of the starch is completed by heating the mass between blunt knives rotating at a high speed in a trough. The milky fluid is then diluted to 8° Beaumé, and the germs are separated, dried and pressed. The oil of the wheat amounts to 1.0—1.8 per cent. of the corn. It cannot be obtained by pressure, but is separated by extracting the wheat germs by solvents. The crude oil has a pure yellow colour; it is a non-drying oil, showing a

slight tendency to go rancid. A ton of wheat germs yields about 280 lb. or 30 galls. of oil. The oil is applicable for soap making and might be refined for purposes of food. The extracted cakes are more suitable for cattle fodder than the original germs. The extraction of the oil increases the yield of flour from the wheat, since the oil is an obstacle to the complete separation of the flour.—J. F. B.

GERMAN PATENT.

Fats, Oils, Waxes and the like; Process for the Hydrolysis of — by means of Steam. O. Mannig. Ger. Pat. 160,111, Dec. 29, 1903.

STEAM under a pressure of 8—10 atmospheres is projected against the under side of a plate or baffle mounted in a closed vessel. The neutral fat or oil is forced into the vessel under strong pressure, and on striking against the upper side of the baffle is converted into a spray, which becomes intimately mixed with the steam rising round the edges of the baffle-plate. It is stated that by this process the hydrolysis of the fat is effected in so short a time that the fatty acids do not become discoloured. —A. S.

XIV.—TANNING, LEATHER, GLUE, SIZE.

Pelts; Plumping Effect of Various Organic Acids on —. J. Paessler and W. Appellius. Deutsch. Gerber-Zeit., 1905; through Collegium, 1905, 295–300; 302–305.

THE authors have previously examined the plumping action of lactic, oxalic and other acids (see this J., 1902, 1461) and they have now extended the investigation to formic acid and acid oxalate of potassium, which have lately been recommended for the same purpose.

The quantity of acid absorbed by the pelt and the time in which the maximum of plumping is attained does not depend upon the concentration of the plumping solution only, but largely upon some other insufficiently known factors. The pelt increases in weight as it swells, but it may be considered plump without showing an excessive (maximum) increase of weight and volume. The results tend to show that there is no means of expressing numerically the degree of swelling attained, even if both increase of weight and volume are known. Oxalic acid acts very quickly, and care should be exercised when it is used for plumping purposes. Acid oxalate of potassium, as anticipated, is slower in its action and equally suitable as formic or lactic acid for the plumping process.

—F. K. K.

Leather; Composition of Japanese — J. Paessler. Deutsche Gerber-Zeit., 1905; through Collegium, 1905, 257–260; 265–266.

THE leather examined is manufactured in Jakagimuro in the vicinity of the town of Ilimoji, chiefly from cow and ox hides, without the use of tannin substances. The treatment consists in sprinkling the hides with common salt to prevent putrefaction, and immersing them repeatedly in the river Ichikawa at a certain spot. It is stated that the water of this river exerts a specific tanning action. The hides are finished by "striking out" and oiling them with rape oil. A specimen of white Japanese leather gave the following results on analysis:—

	Per cent.
Water	11.6
Ash	0.6
Fat	4.6
Nitrogen	17.7
Hide substance (calculated from nitrogen)	82.8

Composition of Ash in Per cent.

Alumina (including traces of ferric oxide)	0.14
Lime	0.08
Magnesia	0.09
Sodium chloride	0.02
Sulphuric acid	0.17

The resistance to tearing of the leather amounted to 5.8 kilos. per sq. mm. of cross-section, and the extension at the moment of breaking was 36 per cent.—A. S.

XVI.—SUGAR, STARCH, GUM, Etc.

Sugar; Diffusion Process for the Manufacture of Beet — A. Herzfeld. Z. Ver. Deutsch Zucker-Ind., 1905, 5 835—868.

THE conditions were examined under which diffusion and pressing gave pulp containing the highest percentage of dry solids, the results having an incidental bearing on the recent maceration process of Steffen. Instead of the short maceration at 80° C. adopted by him, it was found that richer products which would press equally well could be obtained, if the temperature of the juice were raised only to the coagulation point of albumin, and, consequently to that of the agglomeration of the protoplasmic contents of the cells, that is, not higher than 75° C. provided the duration of the maceration were correspondingly prolonged. The general conditions to be observed when the whole of the press water is returned to the battery are as follows:—(1) The preparation of sharp-cut chips, which give as little fine pulp as possible in pressing and which have a good firm consistency; overheating in the battery must be avoided. (2) The exhaustion should be as slight as agricultural conditions will allow, having regard to the relative values of sugar produced at the factory as compared with the value of the pulp fodder. (3) The pressing should be as slight as possible without materially increasing the cost of the subsequent drying process, since with stronger pressure more pectous and albuminous substances find their way into the press water, and these are only partially precipitated by defecation with lime, the metaplectic acid of Scheibler forming a soluble lime salt. When these conditions are observed, it is possible, with a short-cut battery, to obtain pulp with as high a percentage of dry solids, and a juice as rich in sugar, as by the use of special maceration trough. One point worthy of notice was remarked during the investigation, namely, that when the chips used had partially dried or withered, the swelled and increased in weight more than could be accounted for by the juice and water left adhering to them. Chips from stored beetroots in good condition when treated similarly showed a slight diminution in weight. —L. J. DE W.

Juices of [Beetroot] Sugar Works; Formation of Jelly — C. Maassen. Arb. a. d. biolog. Abteil. f. Land u. Forstwirtschaft, am Kais. Gesundheits-Amte, 5, 1—3. Chem. Centr. 1905, 2, 908—9.

Streptococcus (Leuconostoc) mesenteroides was not found in a filter-press cake in which formation of gum had occurred, but a spore-forming bacterium of the group of bacilli causing a red colour in potatoes, which give a culture media containing sugar a jelly-like consistency. These bacilli consist of various species difficult to separate one from the other. The commonest form, from its pear or spindle shape is named *Semidostridium communis*. During the formation of gum from the cane sugar present, hexoses, carbon dioxide, alcohol, formic, acetic, and d-lactic acids are produced, whilst potassium nitrate is denitrified. This organism appears to be the agent bringing about foaming fermentation of sugar juice. As it is not very sensitive to strong solutions of calcium chloride, a broth containing 5 or 6 per cent. of this salt may be used to separate it from other organisms in mill-ferries, or soil, with or without the addition of glycerol at 40°—50° C. —L. J. DE W.

Defecation and Carbonating [Beetroot Juice]. Besson and Rosset. Bull. Assoc. Chim. Sucr. et Dist., 1905, 2 80—86.

THE authors endeavoured, by laboratory experiments, to decide on the relative merits of hot and cold defecation. It was found that when the time of contact of lime with the juice is prolonged, the quotient of purity first increases and then diminishes, the maximum being more quickly reached when the temperature is higher; at 50°—55° C. the maximum is attained in half an hour. The quantity of calcium salts dissolved by the juice increases uniformly with rise in temperature, but the amount only becomes appreciable in 8 to 10 hours at 50°—55° C. The colour

f the juice is not affected by prolonged contact in the cold, but becomes darker with rise in temperature. These results show that the conveyance of med juice in the Linnard pipe system has no injurious effect since the temperature is not high and the time of exposure is rarely prolonged. The scums of the cold defecation are greasy and voluminous, and the viscosity increases with the time of contact; in hot defecation this does not occur. Cold liming, therefore, means slow filtration and loss of sugar, outweighing any economy of time. Juices defecated hot show a lower alkalinity than those treated cold; the escape of ammoniacal vapours can scarcely explain this phenomenon since it is equally evident in juices taken immediately after liming. The cold defecation, however, appears to yield stable precipitates of colouring matter and lime, thus giving juices which may be carbonated completely without showing the dark discoloration which juices defecated hot would give under these circumstances. Increasing the amount of lime reduces a better quality of juice but is limited by the cost. Dilution of juice contributes slightly to augmentation of purity. Oxidising the raw juice by passing a current of air or oxygen through it, did not affect the result in the case of the carbonated juice, but it is quite different in the case of limed juice. There is then a marked diminution of purity and increase in calcium salts.—L. J. DE W.

ENGLISH PATENTS.

Milk Sugar and Casein from Milk; Process of Obtaining — J. R. Hutmaker, Paris, Eng. Pat. 21,860, Oct. 11, 1904.
When separated or ordinary milk is evaporated to dryness, the casein becomes insoluble in water. Dried milk, prepared in any suitable manner, is treated with water as to extract the milk sugar in the form of a concentrated solution, which is purified and evaporated, whilst the washed casein remains behind.—J. F. B.

UNITED STATES PATENTS.

Sugar; Composition [Sulphonated Rosin Oil] for Cleansing —, and *Process of Making same*. C. A. Spreckels and C. A. Kern, Assignors to Federal Sugar Refining Co., Jersey City. U.S. Pat. 799,876, Sept. 19, 1905.
Compound for cleansing sugar is made by sulphonating resinous or oleaginous substance (e.g., rosia oil) at a low temperature, separating the sulphonated compound from the mixture, and dissolving it in a hydrocarbon (e.g., kerosine). (See also U.S. Pats. 698,150 and 60,099 of 1902; this J., 1902, 715 and 784.)—T. F. B.
Gum Tragacanth from Locust Beans; Obtaining —. R. Gray, G. Osborn, H. B. Stocks and H. G. White, Assignors to The Gum Tragacanth Supply Co., Ltd., Hooton. U.S. Pat. 800,369, Sept. 26, 1905.
See Eng. Pat. 27,186 of 1903; this J., 1904, 1156.—T. F. B.

FRENCH PATENTS.

Sugar Syrups [Masseccuits]; Continuous Apparatus for Boiling. H. Roy. Fr. Pat. 353,817, April 29, 1905.
The principle described in Fr. Pat. 353,317 (see this J., 1905, 1024) for boiling two layers of masseccuite of different densities in the same pan, and for withdrawing a portion of the bottom layer without breaking the vacuum, may be extended, so as to make the process really continuous, by increasing the number of separate boiling systems to such an extent that the lowermost layer is always ready for discharging. The diagrams show, in section and in plan, an arrangement containing four superposed boiling systems, each provided with separate circulating apparatus, re-heater and mixer. The pan consists of a wide upper part A and a narrower, elongated lower portion A₁. Four circulating pumps, P, withdraw masseccuite from the pan A₁ at four different levels through the tubes G₁ and deliver it, after the admixture of feed syrups of

FIG. 1.

FIG. 2.

suitable concentrations, through the re-heaters D-D₃ on to the tables G-G₃ situated in the evacuated space of the upper portion of the pan. From these tables the masseccuits are delivered through the pipes F-F₃ each to a lower point of the pan A₁ than that from which it was withdrawn. The basis of fine grain, on which the masseccuite is built up, is prepared in an external evaporator and delivered through a pipe U and overflow L into the top section of the pan A₁. A perforated metal filter O is adjusted at the surface of the contents of the pan, so as to enable any accumulation of syrup to be removed from the system if necessary. The finished masseccuite is withdrawn continuously from K.—J. F. B.

Inulin and Levulose; Process of Preparing —. The Levulose Co., Ltd. Fr. Pat. 353,670, April 25, 1905.

Ligneous "Starch" ("Amidon de lignine"). Amyloid, Dextrose and Alcohol from Wood Wastes; Process of Manufacture of —. Mlle. M. Holabek. Fr. Pat. 353,730, April 27, 1905. XVII., page 1079.

GERMAN PATENT.

Sugar Solutions Obtained from Wood Containing Tannin; Process for Rendering — Easily Fermentable. A. Classen. Ger. Pat. 161,644, Nov. 22, 1904.

Up to the present fir has been the only kind of wood used for the preparation of sugar solutions by inversion. If woods containing a considerable quantity of tannin be used, the sugar solutions obtained are not readily fermentable owing to the presence of gallic acid. According to the present patent, the gallic acid is precipitated by the addition of a suitable salt, for example, ferrous sulphate. The free acid is then neutralised by the addition of calcium carbonate, and calcium hydroxide is added in small portions until the solution has a faintly alkaline reaction.—A. S.

XVII.—BREWING, WINES, SPIRITS, Etc.

Barley; Valuation of —. C. Bleisch and P. Regensburger. Z. ges. Brauw., 1905, 28, 625—631.

The authors have studied in the case of about 80 samples of barley, principally of Bavarian origin, the variations of the different factors which influence the malting value from the economic point of view, and have compared the relative variations amongst each other by means of curves. As the protein-content of the barley increased, the yields of extract both from the barley and the malt prepared from it decreased. The curve for the malt extract was not exactly parallel to that for the barley extract, owing probably to differences in the composition of the substances lost in the malting process. The maximum yield of extract, both with the barley and the malt prepared from it, did not correspond with the minimum protein-content (8 per cent.), but occurred at a protein-content of about 9 per cent. The size of the corns decreased with increase in the protein-content of the barleys, and the maximum size corresponded with the maximum yield of extract. The proportion of hulls, varying in the barleys examined between the limits of 8.0 and 10.1 per cent., increased as the protein-content increased, i.e., with decrease in the extract values. The coarse-hulled barleys contained a larger proportion by weight of hulls than the fine-hulled barleys. The loss of dry weight during the malting process was determined both on the large scale and in the laboratory. It was remarked that determinations of malting loss in the laboratory alone, afforded no measure of the losses occurring on the large scale, owing to the difficulty of maintaining constant temperature and other conditions on the large scale. The loss of substance during malting on the large scale varied very erratically when compared with the protein-content, but there was a general tendency for the loss of weight to increase with the protein-content. This tendency was perfectly well defined in the case of malting experiments in the laboratory, where, owing to perfect control, the variations were more regular.

As a general rule the yield of extract from the malt varied inversely as the loss of weight which had been suffered during malting, but the curves showed great irregularities. The best measure for the valuation of barley from an economic standpoint is the extract yield of the malt referred to the barley dry substance, since it includes both the yield of malt and the extract yield of that malt. The curves showed that with increase of the protein-content of the barley, the yield of malt extract derived from the barley substance decreased, both under practical conditions of malting and in the laboratory. The protein-content of the malt was not proportional to that of the barley, but the loss of protein in malting increased with increase of the protein-content of the barley.—J. F. B.

Barley; The Degree of Mellowness of — and its Relation to the Protein-Content. E. Prior. Allgem. Z. Bierbrau und Malzfab., 1905, 33, 345.

STEELINESS in barley may be of two kinds, one of which

has no effect on the proper modification of the malt, whilst the other kind yields steely, badly modified malt. In order to distinguish between real and apparent steeliness, the barley is submitted to the cutting test both in its original form and after steeping and re-drying. The author has worked out a formula for expressing the true condition of the barley endosperm on the basis

of these two tests:— $A = \frac{(M_1 - M)100}{100 - M} + M$, where A = the

degree of mellowness of the barley and M = the percentage of mealy corns in the original state, whilst M_1 = the percentage of mealy corns after steeping and drying. In this formula the first portion gives the percentage of corns which have become mealy after steeping and drying. The author points out, however, that the mealy corns originally present in the sample, give the best results in practice, and the value represented by A is the percentage of corns which have been made mealy, plus the percentage of originally mealy corns in the sample. The author has endeavoured to correlate the degree of mellowness thus determined with the protein-content of the barley. He found that, although certain individual values and extreme numbers showed no definite relations, yet, when the barleys were divided into classes containing those with equal or nearly equal protein-contents, the average values for mellowness indicated that the percentage of steely corns tends to increase with increase in the protein-content. Thus barleys rich in protein may be, but are not necessarily, badly adapted for malting and brewing; the question is rather one of the nature of the proteid constituents. The author has further remarked that the degree of mellowness of barleys varies in different years.—J. F. B.

Saccharomyces Thermaetitonum. G. Johnson. J. Inst. Brewing, 1905, 11, 466—480.

S. Thermaetitonum (see Eng. Pat. 10,093 of 1903; this J., 1904, 499) is a yeast which resists pasteurisation at 180° F. for a certain length of time, and which performs its functions of budding and fermentation most energetically at temperatures between 105° and 112° F. It readily forms spores on gypsum blocks at 25° C., and is therefore a true saccharomyces. It shows certain peculiarities in its demands for nutrition, and all-malt worts, especially those mashed on the English plan, are not suitable media for its industrial application. This yeast possesses an unusually high inverting power, which must be utilised if the best results are to be obtained. Further, the cell structure does not appear to be adequately provided for by malt alone, and in such worts the yeast becomes brown and does not "break." The peculiarity of the carbohydrate nutrition can be accommodated by restricting the malt diastase by high mashing temperatures, but the best results are got by mashing an unusually large proportion (35—40 per cent.) of flaked maize or rice with the malt, or else by the addition of crystallised cane sugar. Worts made from malt alone also appear to be too rich in nitrogen for the proper development of the yeast. These peculiarities, in addition to the very high temperature of fermentation, make this yeast eminently suitable for fermentation industries in tropical climates. In working with this yeast, it is advisable to discard the mash tun and to work with a converter for the raw grain and a filter-press for the mash. Wort-refrigerators are entirely suppressed, and the boiled, hopped wort is run through a cooling coil into the fermentation vessel. Fermentation, dropping and racking vessels should be made of enamelled metal or some equivalent material, capable of being sterilised by steam. The vessels should be practically closed and only supplied with filtered air. Freedom from infection at all stages is an absolute essential. Fermentation takes place with extraordinary rapidity, and the yeast settles out in remarkably compact clots.—J. F. B.

Saccharomyces Cerevisiae; Influences regulating the Reproductive Functions of —. A. J. Brown. Chem. Soc. Trans., 1905, 87, 1395—1412.

PREVIOUS investigations (Chem. Soc. Trans., 61, 369 and 65, 911) had shown that the reproduction of yeast under

normal conditions is limited by the volume of the liquid in which the yeast grows, and is independent of the number of cells originally sown, and, within wide limits, of the quantity of nutrient available. The author has now studied the relative rates of cell reproduction under varying conditions of crowding, by sowing increasing numbers of cells in equal volumes of liquid and counting the number of cells present per unit volume after a constant interval of time. The results showed that reproduction proceeds at a maximum rate when the number of cells present is at a minimum, and that the rate of reproduction falls with a decreasing velocity as the number of cells sown is increased. From this latter observation it would appear that the arresting influence of crowding is not due to the accumulation of injurious products of cell metabolism, but rather to the exhaustion of some influence which originally favours the reproduction. The author disposes of the theory of the specific arresting action of metabolic products (see Delbrück; this J., 1903, 154) by testing the influence of the volatile, non-volatile and gaseous products of fermentation upon the rate of reproduction separately. The only product which caused any appreciable retardation of the reproductive function was the alcohol, and this was without any marked action on the rate of reproduction until the quantity initially added to the liquid exceeded 3 per cent. If the quantity of alcohol produced during the fermentation were taken into account, it seemed probable that the rate of reproduction of yeast was uninfluenced by proportions of alcohol below 5 per cent. The author concludes that the essential factor in cell reproduction is the presence of oxygen in the liquid, and that reproduction comes to an end when the original supply of oxygen dissolved in the liquid is exhausted. Consequently, when the supply of oxygen is constantly renewed by passing a current of air through the liquid, the influence of the volume on the reproductive function is removed and the limit of reproduction is then determined by the quantity of nutrient matter present.

—J. F. B.

Fermentation in Presence of Rosin. J. Effront. *Monit. Scient.*, 1905, 19, 721–722.

WHEN a saccharine liquid is fermented by a pitching yeast containing a small infection, say, 5 per cent., of bacteria, a selective sedimentation takes place during fermentation. A layer of very nearly pure yeast will be found at the bottom of the vessel, but in samples taken at higher levels the ratio of bacteria to yeast cells will be found to increase in proportion to the distance from the bottom, until, near the surface, 400–450 bacteria may be counted for every 100 yeast cells. Thus it happens that a small infection of bacteria may have a chance of developing and producing disastrous results, owing to the removal of the deterrent influence of the yeast, which, if it could be maintained in its original proportions, would eventually suppress the bacteria altogether. It is claimed that the rosin process of fermentation (this J., 1903, 223, 876) produces this desired result. The addition of 0.3–0.5 gm. per litre of rosin soap to the wash at the time of pitching produces a uniform milky turbidity which subsequently “breaks” to a flocculent precipitate. The action of the rosin is a physical one; in the first phase it weights the bacteria relatively more than the yeast, so that the specific gravity of the two becomes virtually the same; in the second phase, the coagulation ensures the contiguity of the bacteria with a preponderant number of yeast cells. By this process, which is employed for the manufacture of 90 per cent. of all the molasses spirit now produced in France, sterilisation of the washes can be omitted, whilst only as much sulphuric acid as is necessary to neutralise the molasses is employed.—J. F. B.

Metals; Corrosion of — by *Denatured Spirit*. G. Heinzelmann. *Z. Spiritusind.*, 1905, 28, 368–369.

IN continuation of his study on the corrosion of metallic surfaces by denatured spirits (see this J., 1904, 995), the author observes that aluminium is to be added to the list of metals which are somewhat readily attacked. The different denatured wood-spirits of commerce show considerable variations in composition and in the

readiness with which they corrode metals. The corrosive influence of the wood-spirit is ascribed to the esters contained therein, the proportions of which vary between wide limits. Those wood-spirits which contain the lowest proportions of esters are the most suitable for denaturing purposes. The esters and the aldehydes can be destroyed by suitable treatment with caustic soda in the process of rectifying the wood-spirit; the acetone and acetals are unaffected by this treatment.

—J. F. B.

ENGLISH PATENT.

Brewers' Wort and the like; Apparatus for Heating or Boiling —. H. J. Wotssam, London. Eng. Pat. 10,198, May 15, 1905.

A SINGLE or multiple steam drum is supported on feet inside the pan, at such a distance from the bottom that free circulation of the liquid can take place beneath it. The drum is fed with steam either through one of its feet suitably extended inside the drum for the purpose or through a central column. The condensed water is withdrawn in a similar way from a recess in the bottom of the drum, or in the central column. The sides of the drum and the circulating tubes are so attached that no sharp corners or pockets are present in which deposits might settle. A composite form of steam drum, made up of a series of superposed cylinders, of continuously reduced diameters, and provided with circulation tubes, is also described.—J. F. B.

UNITED STATES PATENT.

Brewing; Art of —. J. Schneible, Assignor to the J. Schneible Co., Weehawken, N.J. U.S. Pat. 799,407, Sept. 12, 1905.

IN preparing malt for mashing, the hulls only of the malt are moistened, the starchy portion is then ground well dry to a fine powder, and the whole is carried forward by a current of air, through a machine which moistens the mixture, and finally into the mashing where the mashing is completed.—J. F. B.

FRENCH PATENTS.

Ligneous "Starch" ("Amidon de lignine"), Amyloid. *Dextrose and Alcohol from Wood Wastes; Process of Manufacture of* —. Mlle. M. Hohnbeck. Fr. Pat. 353,730, April 27, 1905.

THE raw material is digested for about 72 hours with a 2–5 per cent. solution of a manganate or permanganate; it is then boiled, filtered and pressed. The solid matter is then mixed with dilute sulphuric acid until it is completely gelatinised. The amyloid or “starch” is then thrown out by a 5 per cent. solution of sodium sulphate and is saccharified by boiling with a suitable quantity of acid; the solution is finally neutralised and fermented. If the oxidation be effected by a manganate in presence of hydrochloric acid, the addition of sodium sulphate is not necessary. If it be desired to obtain the cellulose, the raw material is digested for 70 hours with dilute alkalis, acids or salts, and the amyloid in the extract is saccharified by acids.—J. F. B.

Phlegms, Wines and Fermented Musts; Continuous Direct Rectification of —. A. Baudry. Second Addition, dated July 6, 1904, to Fr. Pat. 338,992, Aug. 19, 1903 (see this J., 1904, 1107).

THE volatile impurities in the alcoholic vapours coming from the distillation column are classified and concentrated on the plates of a double separating column, provided with a refrigerating condenser, in two distinct zones, from which they are continuously removed as they accumulate, so that the intermediate alcoholic liquid of the neutral zone is practically freed from volatile impurities, but still retains odours, which are removed by the injection of direct steam at a higher temperature than that in the column on the plates of which the alcoholic liquid is boiling. The liquid thus purified is passed into the rectifying column. Means are provided by which the “tail products,” which, having escaped the first

action of the separating column, have passed into the rectifying column are returned to the separating column.

—J. F. B.

Phlegms, Wines and Alcoholic Liquids: Continuous Rectification of —. A. Baudry. Second Addition, dated July 9, 1904, to Fr. Pat. 339,079, Oct. 2, 1903. (See this J., 1904, 1231.)

MEANS are described for the continuous elimination of the higher boiling impurities which may have found their way into the rectifying column, and which would contaminate the spirit if no exit were provided for them other than the upper part of the rectifying column. The most impure products from the lower plates of the rectifying column are passed in the form of vapours into the separating column for the "tail products," by employing a small special column, which also receives the impure returns from the above separating column, so as to avoid mixing these two very impure returns with the fresh liquid in the distilling column.—J. F. B.

Phlegms, Wines and Alcoholic Liquids: Continuous Rectification of —. A. Baudry. Third Addition, dated July 15, 1904, to Fr. Pat. 339,079, Oct. 2, 1903. (See also preceding abstract.)

THE least contaminated alcoholic liquids from the upper plates of the lower part of the rectifying column are purified in the preliminary distillation column in which the fresh wine is first treated. The most impure fractions, highly charged with "tail products," are concentrated in a special column, and the alcoholic vapours derived from this special column are treated in the concentrating column devoted to "head products." The concentration of "tail products" is effected either by a condenser or by alcoholic liquids derived from the neutral zone of the "head products" concentrating column, or from one of the plates of the rectifying column, in regulated proportions.—J. F. B.

Rectifying Apparatus for Stills. J. Guillaume. Fr. Pat. 354,074, April 26, 1905.

THE apparatus is intended for the distillation of weak alcoholic liquors. The vapours from the still are first bubbled through a layer of the condensed distillate, and then pass in succession through a perforated plate, a perforated horizontal coil cooled by condensed liquid, a compound seal cup plate, a hollow seal cup plate, the seal cup being cooled by a current of liquid, and finally another perforated plate. No limit is placed on the number of the plates in the apparatus.—W. H. C.

Sewage and other similar Sludges; Treatment of —. [Recovery of Fatty Substances]. F. M. Spence, H. Spence, and P. Spence and Sons, Ltd., Manchester, and R. Ockel, Lower Walton. Eng. Pat. 23,640, Nov. 2, 1904.

THE solid press-cake yielded by the process described in Eng. Pat. 12,124, 1900 (this J. 1901, 830, and 1904, 334), is treated with sufficient mineral acid, preferably sulphuric acid, to decompose the soapy matters present. The cake is then re-dried and the fatty matters extracted by means of a suitable solvent. The quantity of acid added depends on the nature of the sludge, and the mixing may be carried out in a mortar mill.—W. P. S.

FRENCH PATENTS.

Water; Process for the Purification of —. J. D. Delavierre. Fr. Pat. 353,910, May 3, 1905.

THE process more particularly applies to the purification of dirty river water. After a preliminary straining and settling, the water is allowed to flow through a number of cylindrical vessels placed in series so that each stands at a slightly lower level than the preceding one. The water as it enters each of these vessels passes down a side partition and then rises up the centre of the vessel where it is subjected to the action of a current of electricity. On leaving the last electrolytic vessel the water is conducted into a settling chamber provided with baffle plates, &c. Means are supplied for drawing off the sediment from all parts of the apparatus. Chalk or other substances may be added to the water before treatment.—W. P. S.

Water; Process for Dissolving Ozone in — [for Sterilisation]. Comp. Franç. de l'Ozone. Fr. Pat. 354,298, May 15, 1905.

THE water is pumped in at the top of a tall vertical pipe

into which the ozone is also forced. A short distance below the inlet for the ozone, is an "emulsifier" for the purpose of effecting an intimate mixture of the water and ozone. This "emulsifier" may consist of a constriction in the pipe, or of two superposed cones opening into a conical enlargement in the pipe. The water, after admixture with ozone, is discharged from the bottom of the pipe into an outer concentric pipe filled with water, and the sterilised water overflows from the top of this outer pipe, and passes to the delivery pipe.—A. S.

Celluloid, Horn, Ebonite, and similar Substances; Process for Making a Substitute for —. W. H. Story. Fr. Pat. 353,995, May 5, 1905.

COMMERCIAL phenol (50 parts) or an equivalent quantity of another phenol, is boiled with 40 per cent. formalde-

hyde solution (30 parts), for about eight hours in a vessel provided with a reflux condenser. The product is then rapidly concentrated at a temperature somewhat above 100° C., and poured into moulds, when it hardens on cooling, and forms a transparent mass. If an opaque product is desired, a small quantity of a metallic salt or a fatty oil may be added; the product may also be coloured by the addition of a suitable dyestuff. When the substance is still viscous, it may be dissolved in an organic solvent, the solutions serving as varnishes. When it has hardened, it is stated to be insoluble in every solvent, and not attacked by alkalis or acids, excepting fuming nitric acid. (See Fr. Pat. 345,398 of 1904; this J., 1904, 1233.)

—T. F. B.

Celluloid and Similar Substances; Process and Apparatus for Treating Waste —. E. Garbin, and C. and C. Gérard. Fr. Pat. 354,389, May 17, 1905. Under Int. Conv., Dec. 1, 1904.

SEE Eng. Pat. 19,319 of 1905; this J., 1905, 1028.—T. F. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

Quinine Hydrochloride; Neutral —. H. Caritte. J. Pharm. Chim., 1905, 22, 299—303.

THE author has previously stated (this J., 1904, 1041) that neutral quinine hydrochloride, when crystallised from alcohol, contains $1\frac{1}{2}$ mols. of alcohol of crystallisation. C. Erba, having examined the same salt, came to the conclusion that the true formula is

(this J., 1905, 208). The analytical figures obtained by the two investigators were identical, but were differently interpreted. It is now found that when the salt is crystallised from perfectly absolute alcohol, it forms white opaque cauliflower aggregations of needles containing 1 mol. of alcohol; this new salt has therefore the formula $C_{20}H_{24}N_2O_2 \cdot 2HCl + C_2H_6O$. When exposed to the air, these crystals rapidly part with their alcohol, and absorb $2\frac{1}{2}$ mols. of water. When the salt is crystallised from ordinary absolute alcohol, containing traces of water, the crystals obtained contain 1 mol. each of alcohol and water, of which the whole of the alcohol and $\frac{1}{2}$ mol. of water are lost on drying in dry air at 37° C. From a mother liquor consisting of absolute alcohol to which a trace of water was added, crystals having the formula $C_{20}H_{24}N_2O_2 \cdot 2HCl + C_2H_6O + H_2O$ were obtained; these occur as large transparent crystals, unstable in the air, losing 1 mol. of alcohol, and forming the salt with $2\frac{1}{2}$ mols. of water, similar to the salt obtained by crystallisation from an aqueous medium.—J. O. B.

Quinine Salts and Salts of Ammonium. P. Guignès. J. Pharm. Chim., 1905, 22, 303.

It has previously been recorded that the presence of ammonium arsenate in the mother liquor facilitates the crystallisation of quinine arsenate. The phenomenon is found to be general. With quinine sulphate, dissolved by means of a small amount of sulphuric acid, and neutralised with ammonia, a dense crystalline precipitate is obtained on adding any ammonium salt in sufficient quantity to destroy the fluorescence of the solution. The crystals formed consist of a mixture of quinine sulphate and the quinine salt corresponding to the ammonium salt added. When ammonium oxalate or tartrate are used, however, the resulting crystals consist of pure quinine tartrate or oxalate. If instead of the sulphate of quinine, hydrated quinine freshly precipitated by ammonia and dissolved in the acid corresponding to the salt it is desired to produce, be employed, and the ammonium salt of the same acid be added to the solution, the pure quinine salt readily crystallises out. This method of salting out a given salt of quinine with the corresponding salt of ammonium, affords a ready means of preparing it in a pure state.—J. O. B.

Coniine Alkaloids; Separation of the ——. J. v. Braun. Ber., 1905, 38, 3108—3112.

THE bases to be separated are contained in the hemlock, and consist of coniine, methyl-coniine, γ -coniine and conhydrine. By fractionation, it is possible to separate the bulk of the coniine from the other substances. The mixture of four bases is then distilled until the temperature of 190° C. is reached. The small quantity of residue left is the *conhydrine*. The distillate is treated with benzoyl chloride and sodium hydroxide, which gives benzoylconiine and benzoyl-4-aminobutylpropylketone with the coniine and coniine respectively. These form a reddish oil, which is taken up by ether, and from which the *methylconiine* is separated by shaking with dilute acid. The ethereal solution is dried, concentrated, and treated with ligroin (light petroleum spirit), which precipitates the bulk of the benzoylaminobutylpropylketone. The solution is evaporated, and distilled *in vacuo* up to 220° C. The residue is taken up with ether, and precipitated with ligroin. The precipitate is added to the rest of the benzoylaminobutylpropylketone, from which the *coniine* is obtained. The distillate contains the benzoylconiine which gives the *coniine*. The methylconiine obtained in this separation gives a smaller rotation (positive) than d-methylconiine, and yet it does not appear to be a mixture of d- and l-methylconiine.—C. E. F.

Thebaine; Decomposition Products of ——. [Constitution of Opium Alkaloids.] L. Knorr and R. Pschorr. Ber., 1905, 38, 3172—3181.

AN account is given of the decomposition products of thebaine, and then the more important results obtained by the decomposition of the opium alkaloids and their derivatives, together with references to the literature on the subject, are collected in a table.

At the present time the following facts in respect to the constitution of the opium alkaloids may be regarded as proved. (1) The three alkaloids are derivatives of 3,6-dihydroxyphenanthrylene oxide.

In codeine one, and in thebaine both of the hydroxyl groups are methylated. (2) The divalent complex— $C_2H_4 \cdot N \cdot CH_3$ is attached to the phenanthrene nucleus as a side chain. (3) In thebaine, four, and in morphine and codeine, six of the CH groups of the phenanthrene nucleus are reduced to CH_2 . The six additional hydrogen atoms of morphine are divided among the rings II. and III., whilst the ring I. is a true benzene nucleus. The group $C_2H_4 \cdot N \cdot CH_3$ is attached to the reduced portion of the phenanthrene nucleus.—A. S.

Chelidonium; Chemistry of ——. J. O. Schlotterbeck and B. S. Knapp. Amer. Pharm. Assoc., Sept., 1905. Pharm. J., 1905, 95, 443.

THE authors have made a further study of chelidonium (see this J., 1902, 273), and find that it contains one hydroxyl group. When saturated with hydrochloric acid gas at -29° C., and then allowed to stand in a sealed tube for six days at the ordinary temperature, it is apparently converted into amorphous trichelidonium. By treatment with cold phosphorus pentachloride, a mixture of white amorphous monochlorchelidonium, $C_{20}H_{18}ClNO_4$, and an amorphous lencu compound containing one atom of hydrogen less are produced. On heating with phosphorus pentachloride, the two compounds mentioned above are produced, and also a colourless crystalline chloro-base. This latter yields bright red crystalline salts with acids; the hydrochloride has the composition $C_{20}H_{15}ClNO_4 \cdot 5H_2O$. On oxidation with a mixture of nitric and glacial acetic acids, chelidonium yields a crystalline acid melting above 390° C.—A. S.

Myrtle Oil; New Terpene Alcohol in ——. H. von. Soden and Fr. Elze. Chem.-Zeit., 1905, 29, 1031.

THE characteristic smell of myrtle oil is chiefly due to the

acetic ester of an alcohol having the formula $C_{10}H_{18}O$, which is contained in the higher-boiling fractions of the oil. To prepare the alcohol, the portion of myrtle oil boiling above 160°—180° C. is fractionated repeatedly by vacuum distillation, and a middle fraction of 0.975 sp. gr. is collected. This is hydrolysed with alcoholic potash, and then distilled, first with steam, and afterwards in a vacuum. The crude alcohol is further purified by making the phthalic acid ester (m. pt. 116°), and then hydrolysing. The alcohol is an oil boiling at 220° C. (751 mm.).—C. E. F.

UNITED STATES PATENTS.

Benzoylsalicylic Acid and Process of Making same. E. Bloch, Basel, Switzerland. U.S. Pat. 799,706, Sept. 19, 1905.

BENZOYLSALICYLIC acid is obtained in the form of its sodium salt by the interaction of equal molecules of benzoyl chloride and disodium salicylate in a suitable solvent (e.g., ether); the free acid is prepared by treating the sodium salt with acetic acid. It is sparingly soluble in water, easily in ether, alcohol or chloroform; after recrystallisation from alcohol its m. pt. is 132° C.; it is resolved into salicylic acid and benzoic acid by boiling with alkali.—T. F. B.

Theobromine Sodium Formate and Process of Making same. F. H. Tritschler, Assignor to F. Hoffmann-L. Roche, and Co., Basel, Switzerland. U.S. Pat. 799,764, Sept. 19, 1905.

AN addition product of the composition $NaC_7H_7N_4O_2 + HCOONa + H_2O$ is produced by the action of anhydrous sodium formate on monosodium theobromine in aqueous solution. It contains approximately 62.5 per cent. of theobromine, and dissolves in water, giving an alkaline solution, from which theobromine is precipitated by acetic acid. It is applicable as a diuretic.—T. F. B.

Guania; Process of Making ——. L. Weber, Darmstadt, Germany. U.S. Pat. 799,955, Sept. 19, 1905.

FRENCH PATENTS.

Ether Vapours; Recovery of ——. Soc. J. Jean et Cie and G. Raverat. Fr. Pat. 350,057, July 13, 1904.

THE process for the recovery of ether, either pure or mixed with other gases or alcohol, air or moisture, is based

on the retention of the ether vapour by concentrated sulphuric acid of about 53° to 66° B. The ether is liberated by the addition of water to the acid, and recovered by decantation or distillation.—F. S.

Dialkylbarbituric Acids; Process of Preparing — Farbennfabr. vorm. F. Bayer und Co. First Addition, dated Feb. 7, 1905, to Fr. Pat. 353,278, Feb. 7, 1905. Under Int. Conv., July 6, 1904.

SEE U.S. Pat. 789,902 of 1905; this J., 1905, 749.—T. F. B.

Dialkylmalonylurea [Dialkylbarbituric Acid]; Process for Producing — C. E. Merck, Fr. Pat. 351,355, March 20, 1905. Under Int. Conv., June 17, 1904.

UNDER all conditions of reaction, the condensation of diuret with a dialkylmalonylchloride gives rise only to a dialkylmalonylurea (dialkylbarbituric acid), and not to an eight-membered ring compound as might have been anticipated. This method for the production of dialkylmalonylureas is claimed.—T. F. B.

Ichthylsulphonic Acids, obtained by the Action of Sulphuric Acid on Mineral Oils Containing Chemically-combined Sulphur; Process of Preparing —, and **Separating them from the Sulphuric and Hydrochloric Acids and Organic Salts.** Soc. Anon. de la Thyolcine. Fr. Pat. 353,708, April 26, 1905. Under Int. Conv., April 28, 1904.

"ICHTHYOL oil" is sulphonated in the usual manner, washed with a solution of salt, and then extracted with petroleum spirit to remove the unsulphonated oil. The residue is then dissolved in ether, benzene, or other suitable solvent, and allowed to stand. After a time the solution separates into two layers, which are separated, and the upper (etheral) layer evaporated, when the ichthylsulphonic acids are obtained in a pure condition. Or, if desired, the ichthyl solution may be neutralised with ammonia previous to distillation.

—T. F. B.

Chloroform; Prevention of Decomposition of — by Air and Light; and **Indication of the Decomposition.** P. J. Breteau. Fr. Pat. 353,858, May 2, 1905.

CHLOROFORM is preserved from the action of air and light by the addition of one or more of the following: — Alder pith, cork, wood-pulp, guaiacol, ionone, spermaceti, eraniol, metamethylprotocatechuic aldehyde or acid, lenthol, methylphenyl ether, saffrol, methylene-protocatechuic aldehyde, camphor, terebenthene, ironell alcohol, terpineol, cholesterol. The pith, cork, or wood-pulp may be soaked in a solution of a dyestuff insoluble in chloroform and dried before putting into the chloroform. Any decomposition changes the colour of the dye. (See this J., 1904, 725).—F. S.

Chloroform and Iodoform; Process and Apparatus for Making —. H. S. Elworthy and D. Lance. Fr. Pat. 354,291, May 15, 1905.

CHLOROFORM is prepared by subjecting a mixture of the necessary proportions of methane and chlorine, diluted with some inert gas, such as nitrogen or carbon dioxide, to the action of strong light. The methane is preferably prepared by passing a mixture of water-gas and hydrogen over heated nickel. The mixture is passed through a series of thick-walled glass tubes exposed to sunlight, or other suitable light. By diluting the gases, it is stated that there is no risk of explosion or of too rapid a reaction. The chloroform is converted into iodoform by mixing it with an alcoholic solution of sodium or potassium iodide.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Silver Chloride and Bromide; Colour-sensitive —. L. Günther, Phot. Chronik, 1905, 361. Chem.-Zeit., 1905, 29, Rep., 287—288.

THE various coloured "photochlorides" were prepared by the author from colloidal silver. The rose-red variety could only be obtained by the use of freshly prepared silver and chlorine solutions, or from silver chloride prepared by precipitating very dilute silver nitrate solution with very dilute hydrochloric acid. The plates prepared from the red-violet and purple-red photochlorides, obtained from colloidal silver, were the most sensitive to colour. Photobromides were prepared in a similar manner, but are not so sensitive to colour; when emulsified in the colloidal state in gelatin and ripened, their sensitiveness to light is increased without increase in colour sensitiveness. The red photochloride gives plates which are most highly colour sensitive, the blue and violet of a spectrum being best rendered, followed by the yellow and red; green is only rendered as bluish-green. A feeble spectrum image on a photochloride plate can be improved by immersion in mercuric chloride solution. A mixture of photochloride and photobromide is not more sensitive than the photochloride; the colour sensitiveness is not improved by the addition of Erythrosin or a cyanine. The author considers, with Wiener, that the colours produced are "body colours," since, on printing a spectrum on to one already printed, the colours of the original spectrum are destroyed, and those of the second one take their places. (See this J., 1888, 230.)

—T. F. B.

Latent Image; So-Called Destruction of the —. Lüppo-Cramer. Phot. Corr., 1905, 42, 319. Chem.-Zeit., 1905, 29, Rep., 288.

THE author finds that by treating the latent image with certain reagents, e.g., nitric acid, bromine water, chromic acid, and halides of heavy metals, it is not destroyed, as has been previously contended, but that the subsequent development is very greatly retarded.—T. F. B.

Negatives; Composition of —. Lüppo-Cramer. Phot. Corr., 1905, 42, 319. Chem.-Zeit., 1905, 29, Rep., 288.

NEGATIVES which have been immersed for a short time in a 2 per cent. solution of chrome alum and dried, can be treated with reagents which would otherwise destroy the gelatin; thus the silver can be entirely removed from a hardened negative by treatment with nitric acid, ammonium bromide or ammonium thiocyanate; it is also removed without hardening the plate by a solution of chromic acid in two minutes, the gelatin remaining uninjured for some hours; the residue, after this treatment, is of a yellowish-brown colour, and contains no silver chromate; the original image has lost only the feeblest details. When a hardened negative has been treated with ammonium bromide or potassium cyanide, no visible residue is left, but when ammonia and ammonium thiocyanate are used, a distinctly visible image remains. Negatives fixed with thiosulphate are unaltered if immersed for a short while in potassium cyanide or ammonium bromide solution. The residue left after removing the silver from a negative has the following properties: It is unaltered by thiosulphate; bleached by iodine vapour and bromine water; permanently destroyed by Farmer's reducer; is slightly sensitive to light, no metallic silver being produced.—T. F. B.

ENGLISH PATENTS.

Films for Photographic and other Purposes; Manufacture of —. J. H. Smith, Zurich, Switzerland. Eng. Pat. 10,372, May 17, 1905. Under Int. Conv., May 18, 1904.

A GELATIN film, protected on either side by a film of nitrocellulose, and which is said to show no tendency to curl up, is produced by preparing two component films by

first coating a suitable support (e.g., glass) with a solution of gelatin, and allowing this to dry, and then coating the gelatin with a nitrocellulose solution, allowing it to dry, and stripping from the support. If the resulting film is to be used for photographic purposes, the gelatin side of one of the component films is damped and coated with a sensitive emulsion, and the other is moistened and pressed with its gelatin surface to the emulsion of the other component. If the film is intended for other purposes, the two components are moistened, and their gelatin surfaces pressed together. The process may be slightly simplified by preparing only one film, moistening the gelatin surface, and then doubling it upon itself, so that the nitrocellulose surface forms a protective coating to the gelatin.—T. F. B.

Pigment Process [of Photography] and New Copying Materials for use therein; The —. H. E. Newton, London. For Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 26,456, Dec. 5, 1904.

FRENCH PATENTS.

Sensitising Films of Gelatin, Gum, and similar Products employed for Photographic Purposes; Chromium Preparation for —. Act.-Ges. f. Anilinfabr. Fr. Pat. 354,220, May 11, 1905.

A SOLUTION of an alkali bichromate in acetone and water is employed for sensitising gelatin and similar substances for photographic purposes. The solution may consist of ammonium bichromate, 8 parts; water, 100 parts; acetone, 120 parts. The use of such a solution enables the papers, &c., to be dried in five or ten minutes; it is also stated that prepared papers can be kept much longer without deterioration than those prepared with aqueous solutions.—T. F. B.

Films for Photographic and other Purposes; Process of Making —. J. H. Smith. Fr. Pat. 354,330, May 16, 1905. Under Int. Conv., May 18, 1904.

SEE Eng. Pat. 10,372 of 1905; preceding these.—T. F. B.

Development; Process of Photographic — in which the Gelatin is Hardened at the same Time. Act.-Ges. f. Anilinfabr. Fr. Pat. 354,005, May 5, 1905.

PHOTOGRAPHIC plates, papers, &c., may be developed and hardened at the same time by adding to the developer a chromium salt; the developer should be composed of a reducing agent which works in presence of an alkali sulphite only, e.g., diamino-phenol or diaminoresorcinol. For example, 2 grms. of 2,4-diamino-phenol and 3 grms. of chromic chloride are dissolved in 300 to 400 c.c. of water, and 6 grms. of anhydrous sodium sulphite are dissolved in the solution. Development of a negative occupies about six minutes; the washing and fixing are performed as usual, when the plate can be washed with water at a temperature of 80–90° C. (which takes about 10 minutes), and dried at the same temperature.—T. F. B.

XXII.—EXPLOSIVES, MATCHES, Etc.

ENGLISH PATENTS.

Percussion Caps, Detonators, Igniters and the like for the Ignition and Detonation of Explosives; Impts. in or Additions to the Materials Employed in the Manufacture of —. King's Norton Metal Co., Ltd., London. T. A. Bayliss and H. W. Brownsdon. Eng. Pat. 23,366, Oct. 29, 1904.

IN order to obtain greater efficiency and certainty of action in the igniting materials of percussion caps, &c., a metal (preferably aluminium) or metals in fine powder, are intimately admixed with the igniting substances. Shellac varnish of a sp. gr. of 0.84–0.86 containing 10 per cent. of aluminium in suspension is added to the cap composition in such a manner that the surface of the explosive is completely covered with the aluminium powder when the

varnish is dry. A sufficient excess of potassium chlorate must be present in the cap composition to produce complete combustion of the aluminium. The addition of shellac varnish serves to protect the metallic powder from actual contact with the composition so that any chemical reaction is impossible.—G. W. McD.

Explosive Compounds; Impts. in —. Curtis's and Harvey, Ltd., London, and A. F. Hargreaves, Rosli N.B. Eng. Pat. 26,146, Dec. 1, 1904.

AN explosive for use in blasting and for shells is made by blending a non-detonating granular explosive (gunpowder), with a granular detonating explosive composed of barium or potassium nitrate, mixed with a nitro derivative of benzene, toluene, naphthalene or phenol. The invention consists essentially in making each explosive separately in a granular form, and then blending the two together in a mechanical mixture in such a way that each explosive retains its individuality, and is capable of performing its own special function, without being impeded by the other, as would be the case when the two are incorporated into one intimate mixture.

The gunpowder constituent may consist of potassium nitrate (78 parts), charcoal (17 parts), and sulphur (5 parts); the detonating constituent of potassium nitrate (75 parts) and dinitrotoluene (25 parts), and they are mixed in approximately equal proportions. The explosive produces shattering effects similar to the detonating class of explosives, but does not require the use of a detonator.—G. W. McD.

Priming or Detonating Compositions suitable for Percussion Caps. J. Wetter, London, From Westfälische Anhalt. Sprengstoff-Akt.-Ges., Berlin. Eng. Pat. 27,005, Dec. 10, 1904.

SEE Fr. Pat. 348,721 of 1904; this J., 1905, 636.—T. F. B.

Nitrocellulose, Nitroglycerin and like Explosives; Manufacture of —. E. Hesketh, London and F. A. Willcocks, Sunderland. Eng. Pat. 1416, Jan. 24, 1905.

IN the operations of mixing acids and in those of nitration and separation in the manufacture of nitrocellulose or nitroglycerin, it is proposed to employ compressed air which has been cooled and deprived of moisture by means of refrigeration. The development of heat by the combination of the atmospheric aqueous vapour with the sulphuric acid is thus avoided, and the acid is more easily maintained at the requisite temperature.—G. W. McD.

Explosives; Impts. in High —. R. Imperiali, Naples. Eng. Pat. 14,545, July 14, 1905.

AMMONIUM nitrate (74 parts), antimony sulphide (6 parts) and dinitrobenzene (20 parts) are incorporated together and the mixture kept at a temperature of 100° C. until melted dinitrobenzene covers every particle of the explosive with an impermeable layer which affords protection against the action of moisture. The whole mass is then subjected to pressure until a sp. gr. of 1.7 is attained. The dinitro compounds of toluene and naphthalene are also claimed.—G. W. McD.

UNITED STATES PATENTS.

Explosive. E. Steele, Berlin. U.S. Pat. 799,687, Sept. 19, 1905.

THE explosive consists of a nitrated mixture of resin and starch-meal, together with potassium chlorate and from 0.5 to 5 per cent. of powdered aluminium.—A. S.

Explosive; Nitroglycerin [Nitromonochlorhydrin] —. M. Bielefeldt, Berlin. U.S. Pat. 799,705, Sept. 19, 1905.

Matches; Paste, free from White Phosphorus, for the Manufacture of —. D. L. Barbé. Fr. Pat. 350,052, July 11, 1904.

According to the present invention the tips of the matches are coated with a mixture of two pastes of suitable composition, for example, a mixture of the pastes used for the boxes and heads respectively of ordinary safety matches.—A. S.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS, Etc.

Mercury Pump; Automatic — with Shortened Column of Mercury. L. Ubbelohde. Ber., 1905, 38, 2657—2659.

The pump is similar in construction to the one described by Stock (this J., 1905, 814), except that it is provided with a device whereby it works automatically. To fill the pump, the rubber tubing connected to the upper part of the small glass vessel *c* is detached from the main part of the pump, and mercury is introduced through it until the vessel *U* is filled up to a mark on its upper narrowed portion. The rubber tube is then again fastened to the pump, and mercury is now introduced through *A* until a tube below the valve *f* is immersed to a depth of 3 mm. in mercury in the hemispherical vessel below. A water-pump is then connected to *A*, and the apparatus together with the vessel in which a vacuum is to be proceeded, and which is attached at *R*, is exhausted, the screw device *W* being fixed in the position shown in the figure by the clamp *b*, whilst the three-way cock *H* is open to *A* and *U*. After the desired degree of vacuum is attained, the clamp *b* is loosened, and the pump will now work automatically. The weight of the mercury in *c*

causes the device *W* to move in such a manner that cock *H* is closed against *U*, whilst the latter is put into communication with the air. The mercury, forcing any air before it, rises through the tube *r*, between *f* and *O*, and the vessel *O* itself, until stopped by the valves *d* and *e*. When the level of mercury in *U* has sunk below a certain level, that contained in *c* begins to flow into *U* through the tube *s*, and after a time, the counter-weight *G* causes the device *W* to swing, whereby the cock *H* is turned and *U* is again put in communication with the water pump. The mercury then begins to fall again into *U* producing a Torricellian vacuum in *O*, and after a time *c* fills again and the whole process is repeated. When *U* is in communication with the air, the screw-clamp on the piece of tubing attached to *H* is so arranged that the air enters with great velocity at the beginning; towards the end the velocity is reduced automatically as the mercury rises in *r*, the tube connecting *U* and *O*. —A. S.

Mercury Pump; A Rotating —. W. Kaufmann. Z. Instrumentenk., 1905, 25, 129—133. Science Abstracts, 1905, 8, A, 537.

The pump consists essentially of a glass cylinder partially filled with mercury, and provided with two branch tubes, which are coiled around it in the form of spirals. The cylinder is mounted in a position inclined to the vertical, and, when rotated round its axis, acts in a somewhat similar manner to a fall-pump, owing to the alternate rise and fall of the mercury in the two spirals. From 200 to 250 c.c. of mercury are required to charge the pump, and it is stated that, by its aid, a bulb of 12 cm. diameter can be exhausted in about 12 minutes from 20 mm. pressure to that at which Röntgen rays begin to appear. —A. S.

ENGLISH PATENT.

Gas; Impts. in the Testing of — [Argand Burner]. C. C. Carpenter, London. Eng. Pat. 13,553, July 1, 1905.

A "WANDSWORTH" argand burner is modified by attaching to its socket a vertical threaded pin, on which is mounted a horizontal disc, which may be screwed up or down on the pin, the disc being of diameter sufficient to cover the air inlet to both the inner and outer surfaces of the annular flame. The proportion of air admitted to the burner may thus be regulated. The modified burner is designed for use in the photometric testing, at a standard rate of consumption, of gases of various compositions. —H. B.

Vanadium Compounds; Some — [and the Detection of Hydrochloric Acid]. C. Matignon. VII., page 1035.

INORGANIC—QUANTITATIVE.

Manganese; Determination of —, in Presence of Chromium. M. Gröger. Chem.-Zeit., 1905, 29, 987—988.

The author has adapted Volhard's permanganate method to the determination of manganese in presence of chromium. Zinc hydroxide precipitates some manganese with the chromium from a chromic solution containing manganese. A basic zinc sulphate is, however, satisfactory. It may be prepared by dissolving 288 grms. of pure crystallised zinc sulphate and 28 grms. of pure caustic potash, each in 500 c.c. of water, and shaking them well together in a closed flask. To a measured volume of the sample solution, containing about 0.1 grm. of chromium, contained in a 250 c.c. flask on a boiling water-bath, the zinc "solution" (well shaken) is added, until the precipitate appears no longer green, but violet. The whole is then cooled, water added up to the mark, and the solution filtered through a dry filter. Fifty c.c. of the filtrate are treated with 20 grms. of crystallised zinc sulphate in 150 c.c. of water, the mixture heated to boiling and titrated with N/10 permanganate solution, shaking vigorously. If

chromium be present as a chromate, the solution is first reduced with sulphur dioxide, and the excess of this boiled off after addition of sulphuric acid.—F. SDX.

Arsenic; Determination of — in presence of Vanadium and Molybdenum. C. Friedheim, O. Decker and E. Diem. Z. anal. Chem., 1905, 44, 665–686.

To every 1 grm. of the substance are added 1–1½ grm. of potassium iodide and 70 c.c. of hydrochloric acid (sp. gr. 1.19) and the mixture is distilled at once, without waiting for solution. A 100 c.c. distillation flask with a well-fitting ground-in delivery tube is employed, and in order to avoid liquid being thrown over, the neck of the flask is enlarged at two points. The receiver is cooled by water to prevent loss of arsenic. Much iodine separates at first, and until all this is over, the flame should be carefully regulated to prevent stoppage of the delivery tube. All the arsenic is distilled over in 20 minutes. The distillate is evaporated to a syrup, chlorine-water being added at intervals as an oxidiser. The arsenic pentoxide may then be weighed as such, over phosphorus pentoxide, after evaporation in a platinum dish and heating to dull redness (435°–450° C.), or be precipitated by magnesia mixture. The vanadium and molybdenum in the residue are separated, as usual, by sulphuretted hydrogen, the former being determined volumetrically by permanganate and the latter as trioxide, according to the known methods.—F. SDX.

Phosphoric Acid; Determination of — as Ammonium Phosphomolybdate. G. P. Baxter and R. C. Griffin. Amer. Chem. J., 1905, 34, 204–217.

It has already been shown (this J., 1902, 1351) that the precipitate formed by adding a solution of phosphoric acid to an ammonium molybdate solution containing an excess of molybdic acid, and heating to 300° C., has approximately the formula $(\text{NH}_4)_3\text{PO}_4 \cdot 12\text{MoO}_3$, but that there is always some excess of MoO_3 above what is given by this formula. The amount of this excess of MoO_3 is found to depend on the conditions of precipitation, but under given conditions is constant. Under the following conditions the number 12.143 represents the number of molecules of MoO_3 in the precipitate. The phosphate solution is poured into the molybdate solution with constant stirring, and the solution allowed to stand for 18 hours at the ordinary temperature. The precipitate is filtered through a weighed Gooch crucible, and is washed with a 10 per cent. solution of ammonium nitrate; it is then heated in an air bath to 300° C. for two hours and weighed. If this method be followed, the precipitate, which is obtained at first, is a diammonium phosphomolybdate, but this is converted after heating (in presence of the ammonium nitrate) into $(\text{NH}_4)_3\text{PO}_4 \cdot 12.143\text{MoO}_3$. In carrying out this precipitation the phosphate solution must be poured into the molybdate solution, and not the reverse; it is also important that the precipitation should be carried out in the cold, if constant results are to be obtained.—C. E. F.

ORGANIC—QUALITATIVE.

Formaldehyde; Modification of Hehner's Test for —. A. B. Lyons. Amer. Pharm. Assoc., Sept. 1905. Pharm. J., 1905, 75, 443.

THE Hehner test for formaldehyde can only be applied to milk or a mixture of the solution under examination with milk, as the presence of proteids is essential to the production of the colour reaction. The author recommends the substitution of beef peptone for the milk. Two duplicate tests are made in the following manner: Two c.c. of the solution under examination are mixed with 20 mgrms. of beef peptone in a test-tube, and 2 c.c. of a mixture of 1 vol. of the official (U.S.P.) tincture of ferric chloride with 20 or 25 vols. of concentrated sulphuric acid are introduced, so as to form a distinct layer at the bottom. One tube is then allowed to stand till the colour-zone develops, whilst the other one is shaken in order to mix the contents. The test is stated to be capable of detecting 1 of formaldehyde in 4,000,000.—A. S.

Sesamé Oils of Different Origin; Characteristics of — [and Detection of Sesamé Oil in Butter]. H. Sprinkmeyer and H. Wagner. XII., page 1074.

ORGANIC—QUANTITATIVE.

Coal; Determination of Sulphur in —. O. Brunck. Z. angew. Chem. 1905, 18, 1560–1562.

COBALT oxide, free from sulphur, is prepared by ignition of the pure nitrate at as low a temperature as possible (heating to redness lowers the efficiency of the oxide; small amounts of nitrate left through imperfect decomposition are not harmful). The finely-powdered coal (1 grm.) is intimately mixed in a glass or glazed porcelain mortar with 2 grms. of a mixture of 2 parts of cobalt oxide and 1 part of anhydrous sodium carbonate, and the mixture transferred to a roamy platinum or porcelain boat. This is placed in a wide glass tube, 30 cm. long, through which a stream of oxygen can be led. Experience shows that the far end of the tube may be left open; but, if desired, absorption vessels may be connected there, containing brominated hydrochloric acid, and sodium carbonate solution with a little hypobromite, to catch any sulphur in the escaping gases. Whilst a gentle stream of oxygen passes, the near end of the boat is heated by a very small flame till the coal ignites, when the flame is removed and the combustion is regulated entirely by the stream of oxygen. Near the end, the whole length of the boat is heated gently till combustion is complete—15 minutes is enough for the whole operation. After cooling, the contents of the boat are extracted with water and filtered through a close filter, using a few drops of sodium carbonate with the wash-water to prevent the cobalt oxide from passing through the filter. The filtrate is warmed with a few c.c. of hydrogen peroxide acidified, and precipitated by barium chloride in the ordinary way. With certain coals the cobalt oxide retains sulphur probably as basic sulphate; if this be suspected, the residue on the filter is dried, the filter incinerated, the whole dissolved in a little hydrochloric acid, filtered, and the filtrate treated with barium chloride, any precipitate being added to the main portion. Comparison of this method with Eschka's and the bomb methods show that usually all give concordant results, but that differences sometimes occur between Eschka's method and the others, seldom between the other two. The method is much quicker than Eschka's, excludes the possibility of error from sulphur from the products of combustion of the gas, and allows of any sulphur escaping in the gaseous products being caught and determined.—J. T. D.

Petroleum and Liquid Fuels; Determination of Sulphur in —. A. Goetzl. Z. angew. Chem., 1905, 18, 1528–1531.

To determine the sulphur in liquid fuel, 2–3 grms. of the oil are weighed into a large platinum crucible, and treated with 4 c.c. of fuming nitric acid. The crucible is covered with a watch-glass, and the two layers of liquid allowed to mix gradually, violent action being avoided. The crucible is allowed to stand over night, and is then gently heated on the water-bath. When all action appears to have ceased the watch-glass is removed, and heating on the water-bath continued until the contents are dry. 6–8 grms. of mixture of pure sodium carbonate and potassium nitrate (5:1) are stirred in, and a layer of this mixture placed on the top. The crucible is then heated with a free flame until the contents are quite white, a little nitre being added if necessary. The resulting mass is dissolved in warm water, hydrochloric acid and barium chloride added, and the sulphur calculated from the barium sulphate obtained.

In the case of a light oil (petroleum) the same method is applicable; 10 grms. of the petroleum are taken, and 12 grms. of the sodium carbonate and nitre mixture are required. The method also gives good results with lignite coals, and animal oils.

For the determination of water in liquid fuel, the method recommended, is the ultimate analysis of the oil before and after drying it with calcium chloride.

—C. E. F.

Gambier or Yellow Catechu; Determination of the Value of —. M. Greshoff. Pharm. Weekblad, 1905, 42, 669—676. Chem. Centr., 1905, 2, 993.

Solubility.—Five grms. of the sample are shaken with one litre of water, heated nearly to boiling, the mixture is allowed to stand in the dark for 24 hours, and the amount of soluble matter in 100 c.c. of the filtered solution determined, the evaporation residue being dried for three hours at 105° C. **Tannin.**—125 grms. of the aqueous extract are shaken vigorously with 2.5 grms. of "voluminous" aluminium chloride, the mixture is allowed to stand for 24 hours, and the evaporation residue of 100 c.c. of the filtered solution determined as described above. The difference between this and the total soluble matter represents the amount of tannin. **Crude Catechin.**—Two grms. of the sample are finely ground up with an equal weight of pumice, and the mixture is shaken vigorously with 50 c.c. of ethyl acetate. After allowing to stand for 24 hours the solution is filtered, the residue washed twice with 5 c.c. of ethyl acetate, and the evaporation residue of the filtrate determined. The difference between this and the weight of tannin represents the amount of crude catechin. **Crystallised Catechin.**—The mixture of crude catechin and tannin is dissolved in 10 c.c. of warm water, the solution filtered and the residue washed with 5 c.c. of warm water. The filtrate is set aside to crystallise, but if no catechin separate, 0.1 gm. of the pure substance is added, and is subsequently deducted from the total quantity obtained. It is stated that catech or brown catechu does not yield crystallised catechin by this method. **Water.**—2 grms. of the sample are finely ground with 2 grms. of pumice, and the mixture dried at 105° C.

A sample of unadulterated gambier gave the following results on analysis:—Insoluble matter, 7.6; tannin, 24; crude catechin, 46; crystallised catechin, 30—35; water, about 15; and ash, at the most, 5 per cent.—A. S.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Grignard's Reaction. A. Baeyer. Ber., 1905, 38, 2759—2765.

GRIGNARD found that magnesium acts on the bromine and iodine derivatives of fatty hydrocarbons in ethereal solution; also that it acts on the halogen derivatives of the aromatic hydrocarbons if a small quantity of iodine be added. Baeyer and Villiger (this J., 1903, 1124) were unable to obtain a similar reaction with halogen derivatives of aniline and dimethylaniline, but Sachs and Ehrlich (this J., 1904, 56) found that the reaction takes place if a little ethyl bromide be used to start the reaction. This last method has, however, some disadvantages. The author has found that finely divided magnesium acts on the halogen derivatives of aniline, if it receive a thin coating of magnesium iodide before being introduced into the ether. To prepare magnesium in the "active" condition, magnesium filings are heated in a round-bottomed flask, and half the weight of iodine added in small quantities at a time; each portion of iodine is allowed to disappear before the next is added, and the temperature is not allowed to rise above the melting-point. The product turns brown if kept, and moisture must be carefully excluded. Such magnesium acts energetically on methyl alcohol, and somewhat less so on ethyl alcohol and water. In ethereal solution, it is without action on chlorobenzene, but acts violently on bromobenzene. It acts on all the iodo-substitution products from aniline and dimethylaniline; the action is most violent with the ortho-derivatives, and weakest with the para-compounds. The reaction is carried out as follows: One part of the iodine derivative of aniline or dimethylaniline is dissolved in two parts of ether, and one-fifth part of magnesium added in small quantities at a time. The solution remains colourless in the case of the ortho-derivatives, but becomes dark brown with the meta- and para-derivatives; the solubility of the magnesium compounds varies greatly.

The magnesium compound of the iodo-derivatives of dimethylaniline react with ketones (e.g., benzophenone) in ethereal solution giving derivatives of triphenylcarbinol.—C. E. K.

Hydroxybenzoic Acids; Some Oxidation Products of the —, and the Constitution of Ellagic Acid. A. G. Perkin and M. Nierenstein. Chem. Soc. Trans., 1905, 87, 1412—1430.

By treating gallic acid in acetic acid solution with potassium persulphate and sulphuric acid, ellagic acid, $C_{14}H_6O_8$ is produced. It melts above 360° C., and gives a tetracetyl compound melting at 343—346° C. Protocatechuic acid when oxidised in a similar manner, but without using any acetic acid, gives *catellagic acid* $C_{14}H_6O_6$, probably identical with the compound isolated by Schiff (Ber., 1882, 15, 2590). It melts above 360° C., and gives a diacetyl compound melting at 322°—324° C. Both ellagic acid and catellagic acid yield fluorene on distillation with zinc dust. *p*-Hydroxybenzoic acid, when treated in a similar manner, yields catellagic acid and a compound $C_{14}H_6O_6$, which melts above 360° C., and gives a diacetyl compound melting at 267—268° C. This compound appears to result from the interaction of protocatechuic acid and *p*-hydroxybenzoic acid, and probably has the constitution

from which it follows that catellagic acid has the formula

In a similar manner ellagic acid would have the formula

identical with that proposed by Graebe (compare this J., 1905, 899). *m*-Hydroxybenzoic acid on oxidation with potassium persulphate and sulphuric acid, gives *metellagic acid*,

m. pt. 273°—276° C., which forms a monoacetyl compound melting at 269—271° C.

The authors find that the compound obtained by Barth and Goldschmidt (Ber., 1879, 12, 1237) by the action of caustic potash on ellagic acid, and considered by them to be hexahydroxydiphenylketone, is really the pentahydroxy derivative of the lactone of 2-hydroxydiphenyl-2'-carboxylic acid (diphenylmethylelide) as suggested by Graebe, and this fact agrees with the formula given above for ellagic acid. The dyeing properties of ellagic acid are somewhat anomalous, since the carboxyl group, when present as a portion of a lactone complex, is not usually associated with this characteristic. It is probable, however, that the diphenyl linkage has the effect of rendering these groups less susceptible to hydrolysis, so that a quinonoid form becomes possible. The pentahydroxydiphenylmethylelide mentioned above gives no precipitate with gelatin in warm aqueous solution, and it is doubtful, therefore, whether ellagic acid can be regarded as a tannin matter in the true sense of the word. (Compare this J., 1905, 899.)—A. S.

Ellagic Acid. G. Goldschmidt. Monatsh f. Chem., 1905, 26, 1139—1148.

THE author describes an addition compound of ellagic acid and phenylhydrazine and also the tetramethyl ether of ellagic acid, prepared with the aid of an ethereal solution of diazomethane. In a discussion of recent work on the constitution of ellagic acid, he supports the conclusion of Perkin and Nierenstein (see preceding abstract) that Graebe's formula for this compound is correct.—A. S.

Sulphur in Albuminoid Substances [Wool]; Condition of —. P. N. Raikow. Chem.-Zeit., 1905, 29, 900—901.

Of the elements present in albuminoids, sulphur is the one generally present in smallest quantity, but the sulphur content varies within much wider limits than the amounts of the other elements in different albuminoids. The sulphur compounds which have been isolated, up to the present, from the decomposition products of albuminoids, can all be regarded as derivatives of hydrogen sulphide, and this has given rise to the opinion that the albumin molecule does not contain any sulphur directly united to oxygen. The author has now found that if wool (or human hair) be allowed to stand for some time at the ordinary temperature, in contact with syrupy phosphoric acid (sp. gr. 1.7) in a closed flask, considerable quantities of sulphur dioxide are produced.—A. S.

New Books.

SELECT METHODS IN CHEMICAL ANALYSIS (Chiefly Inorganic). By Sir WILLIAM CROOKES, D.Sc., F.R.S., &c. Fourth Edition, Rewritten and Enlarged. Longmans, Green and Co., 39, Paternoster Row, London, New York and Bombay. 1905. Price 21s. nett.

LARGE 8vo volume, containing 703 pages of subject matter, with 68 illustrations, a final chapter of "Useful Tables," and the alphabetical index. In his preface the author states, that he has rigidly adhered to the rule of "omitting methods of which he has no personal experience," and that he believes that he thus "added to the value of the book as a work of reference." The text is classified under the following divisions:—I. Potassium, Sodium and Ammonium compounds. II. Calcium, Strontium, Barium, Glucinum and Magnesium. III. Cerium, Lanthanum group, Didymium, Europium, Gadolinium, Samarium and Yttrium. IV. Zinc, Cadmium, Gallium, Radium, Aluminium, Thallium. V. Uranium, Vanadium, Molybdenum, Tungsten. VI. Chromium, Iron, Manganese, Nickel, Cobalt. VII. Silver, Mercury, Copper, Lead and Bismuth. VIII. Antimony, Tin, Arsenic, Tellurium and Selenium. IX. Gold, Platinum, Palladium, Iridium, Osmium, Rhodium, Ruthenium. X. Sulphur, Phosphorus and Nitrogen. XI. Iodine, Bromine, Chlorine, and Fluorine. XII. Carbon, Boron, Silicon. XIII. Electrolytic Analysis. Gas Analysis. XIV. Miscellaneous Processes and General Methods of Manipulation.

CHEMISTRY FOR ENGINEERS AND MANUFACTURERS. A Practical Text-Book by BERTRAM BLOUNT and A. G. BLOXAM. VOLUME II.—Chemistry of Manufacturing Processes. Second Edition. Chas. Griffin and Co., Ltd., Exeter Street, Strand, London. 1905. Price 16s. nett.

8vo volume containing 466 pages of subject matter, bibliographic tables filling four pages, and the alphabetical index. There are 46 illustrations. Whilst the scheme of the first edition has been retained, new matter has been added, increasing the pages from 436 to 466; the scheme of the first edition is given in this J., 1896, 926. The work, it is stated, has also undergone complete revision.

SMOKE ABATEMENT. A Manual for the Use of Manufacturers, Inspectors, Medical Officers of Health, Engineers and Others. By WILLIAM NICHOLSON. Chas. Griffin and Co., Ltd., Exeter Street, Strand, London. 1905. Price 6s. nett.

8vo volume, containing 349 pages of subject matter with 59 illustrations, and the alphabetical index. The scheme of the work is furnished under the following

heads:—I. Introduction. II. General legislation against the Smoke Nuisance. III. Local legislation against the Smoke Nuisance. IV. Foreign Laws in regard to Smoke Abatement. V. Smoke Abatement. VI. Smoke from Boilers, Furnaces and Kilns. VII. Private Dwelling House Smoke. VIII. Chimneys and their Construction. IX. and X. Smoke Preventers and Fuel Savers. XI. Waste Gases from Metallurgical Furnaces. XII. Summary and Conclusion.

RESEARCHES ON THE AFFINITIES OF THE ELEMENTS AND ON THE CAUSES OF THE CHEMICAL SIMILARITY OR DIS-SIMILARITY OF ELEMENTS AND COMPOUNDS. By GEOFFREY MARTIN. J. and A. Churchill, 7, Great Marlborough Street, London. 1905. Price 16s. nett.

LARGE 8vo volume, containing 264 pages of subject matter with five woodcuts, and the alphabetical index. There is also one large plate, 14 tables, and three Appendices.

SUBJECT LIST OF WORKS ON AGRICULTURE, RURAL ECONOMY, AND ALLIED SCIENCES IN THE LIBRARY OF THE PATENT OFFICE. Darling and Son, Ltd., 34-40, Bacon Street, London, E. The Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C. 1905. Price 6d.

RADIUM AND RADIO-ACTIVE SUBSTANCES. THEIR APPLICATION ESPECIALLY TO MEDICINE. By CHAS. BASKERVILLE, Ph.D. Professor of Chemistry and Director of the Laboratory, College of the City of New York. Williams, Brown and Earle, 918, Chestnut Street, Philadelphia, Pa., U.S.A. 1905.

8vo volume, containing 152 pages of subject matter, with 67 illustrations, and the alphabetical index. The subject matter is classified in the following groups:—I. Phenomenon of Radio-Activity. II. Extraction of Radium Salts and their properties. III. Other Radio-Active Substances. IV. Emanations of Radium and Induced Radio-Activity, Ex-Radio. V. Theories of Radio-Activity. VI. Physiological Properties and Therapeutic Applications of Radio-Active Substances. VII. Other Therapeutic Radiations.

CEMENTS, LIMES AND PLASTERS: THEIR MATERIALS, MANUFACTURE AND PROPERTIES. By EDWIN C. ECKEL, C.E. John Wiley and Sons, New York. Chapman and Hall, Limited, London. 1905. Price 25s. 6d. nett.

8vo volume, containing 710 pages of subject matter with 165 illustrations and 254 tables, followed by an alphabetical index. The subject matter is classified by arrangement in the following groups:—I. INTRODUCTION. Growth of Cement Industries. Classification and Relationships of Cementing Materials. PART I. PLASTERS. (i) Composition: Distribution and Excavation of Gypsum. (ii) Chemistry of Gypsum-Burning. Manufacture of Plasters. (iii) Composition, Properties, and Tests of Plasters. (iv) Flooring-Plasters and Hard-Finish Plasters. (v) Statistics of the Gypsum and Plaster Industries. PART II. LIMES. (vi) Composition, Origin and General Characters of Limestones. (vii) Lime Burning. (viii) Composition and Properties of Lime. (ix) Hydrated Lime: Preparation and Properties. (x) Manufacture and Properties of Lime-Sand Bricks. PART III. MAGNESIA AND OXYCHLORIDE CEMENTS. (xi) Sources and Preparation of Magnesia. (xii) Magnesia Bricks and Oxychloride Cements. PART IV. HYDRAULIC LIMES, SELENITIC LIMES, AND GRAPPIER CEMENTS (xiii, xiv, and xv). PART V. NATURAL CEMENTS. (xvi and xvii) Raw Material and Natural-Cement Rock. (xviii) Manufacture of Natural Cements. (xix, xx, and xxi) Composition and Properties of Natural Cements, &c. PART VI. Portland Cement (xxii—xli). PART VII. PUZZOLAN CEMENTS. (xli, xlii, xliii and xliv) Slag Cement. Composition and Properties. (xlv) Slag Bricks and Slag Blocks.

SELECT METHODS IN FOOD ANALYSIS. By H. LEFFMANS, Ph.D., M.D., and WILLIAM BEAM, M.D. Second Edition. Revised and Enlarged. Reiman, Limited, 129, Shaftesbury Avenue, London, W.C. 1905. Price 11s. nett.

8vo volume, containing 388 pages of subject matter, with 54 illustrations and an alphabetical index. The analytical methods described, are classified thus:—**I. ANALYTICAL METHODS.** Physical Data, Chemical Data. **II. APPLIED ANALYSIS.** General Methods, Special Methods. The latter are sub-classified under (i) Starch, Flours, Meals and Bread, Sugars, &c.; (ii) Fats and Oils; (iii) Milk and Milk Products; (iv) Non-alcoholic Beverages; (v) Condiments and Spices; (vi) Alcoholic Beverages; (vii) Flesh Foods.

Trade Report.

I.—GENERAL.

Bd. of Trade, Oct. 4, 1905.

INFORMATION ON TRADE MATTERS.

The Board of Trade desires to point out to British manufacturers and merchants who wish to obtain information in regard to trade matters in foreign countries, that it is advisable that applications should first be made to the Commercial Intelligence Branch of the Board of Trade, 73, Basinghall Street, E.C., before communications are addressed to His Majesty's Consular officers abroad. By the adoption of this course much delay would be avoided by the inquirer in cases in which the Intelligence Branch is already in possession of the required information.

FACTORY ACT; REGULATIONS FOR LOCOMOTIVES AND WAGGONS ON LINES AND SIDINGS.

Home Office, Oct. 23rd, 1905.

The Secretary of State for the Home Department, in pursuance of section 81 of the Factory and Workshop Act, 1901, has appointed Mr. Chester Jones, Barrister-at-Law, of 1, Paper Buildings, Temple, E.C., to hold an inquiry with regard to the draft regulations for the use of locomotives and waggons on lines and sidings under the Factory Act, published in pursuance of section 80 of that Act.

The inquiry, which is a public one, will be opened at the Caxton Hall, Westminster, London, on Wednesday, November 22nd, 1905, at 10 a.m., and any person who has objected to the draft regulations and any other person who, in the opinion of Mr. Chester Jones, is affected by them, may appear either in person or by counsel, solicitor, or agent.

SWISS CHEMICAL TRADE.

Chem. Trade J., Oct. 7, 1905.

The Bâle Chamber of Commerce, in its report on the Swiss chemical and colour trades for 1904, states that the tanning material for the Bâle trade comes chiefly from the Levant and China, and it was kept moderate in price. In the course of the year dyewood extracts to the value of 392,000 frs. were exported, against corresponding imports to the value of 341,000 frs. The export of fluid tanning extracts were valued at 337,000 frs., the imports thereof were 470,000 frs.; whereas the export and import figures for solid tanning extracts were 352,000 frs. and 155,000 frs. respectively. The report further shows that in the pharmaceutical-chemical branches good business was done, resulting in a rise in values. The exports under this head, including drugs, alkalis and pharmaceutical preparations, valued 8,400,000 frs., against 7,270,000 frs. in the preceding year. The total value of the exports for 1904 was 17,888,269 frs., the principal customers having been the United States of America, 4,338,734 frs.; Ger-

many, 3,733,309 frs.; England, 2,724,398 frs.; Italy, 1,331,926 frs.; Austria-Hungary, 1,064,809 frs.; and British India, 909,167 frs. The imports, amounting in value to 1,657,875 frs., were almost entirely from Germany.

TRANSVAAL; TRADE OF THE —

Bd. of Trade J., Oct. 12, 1905.

The following tables, showing the value of certain articles imported into and exported from the Transvaal during the six months ended 30th June, 1905, as compared with the corresponding period of the preceding year, have been compiled from official figures published in the *Transvaal Government Gazette*:—

Imports.

Articles.	Six Months ended 30th June.	
	1904.	1905.
	£	£
Metals and manufactures thereof	1,387,000	1,353,000
Drugs and chemicals	212,000	321,000
Leather and manufactures	238,000	270,000
Beverages (includes ale, spirits, wine and mineral waters)	207,000	200,000
Arms and ammunition (includes dynamite and other explosives)	137,000	191,000
Groceries and oilmen's stores (includes oils, paints, turpentine and varnish) ..	142,000	147,000
Soap and candles	115,000	146,000
Glass and glassware	37,000	31,000

Exports.

Articles.	Six Months ended 30th June.	
	1904.	1905.
	£	£
Gold	7,711,000	10,076,000
Diamonds	341,000	628,000
Coal	67,000	46,000
Wool	35,000	37,000
Skins, hides and horns	13,000	24,000

III.—ACIDS, ALKALIS, Etc.

GASES; CARRIAGE OF COMPRESSED — IN INDIA.

Chem. and Drug., Oct. 14, 1905.

The Railway Board of India have issued the following new rules regarding the carriage of compressed oxygen, compressed or liquefied carbonic acid gas, compressed coal-gas, compressed hydrogen, liquefied anhydrous ammonia or compressed ammonia gas, liquefied or compressed nitrous oxide, liquefied or compressed sulphur dioxide:—

1. These gases must be packed in cylinders.
2. Cylinders must be made of wrought iron or mild steel of the best quality, containing not more than 0.25 per cent. of carbon, thoroughly annealed after manufacture, of sufficient strength and efficiently tested, and must not exceed 8 ft. in length and 10 ins. in diameter.

3. Cylinders must be separately and securely packed in a strong wooden case, or in a covering made of closely-plaited 1 in. (circumference) hemp or coir; except that several small cylinders not exceeding 18 ins. in length and 4 ins. in diameter may be packed in one box, provided each cylinder is contained in a separate compartment or is separately incased in closely-plaited 1 in. (circumference) hemp or coir. Each box must not contain more than 25 cylinders, and the gross weight of each box and contents must not exceed 3½ maunds (86.4 lb.).

4. Cylinders containing atmospheric air, coal-gas, hydrogen or oxygen must not be charged to a greater pressure than 1800 lb. per square inch.

5. No cylinder may contain, per pound of water capacity, more than ¾ lb. of carbon dioxide; ½ lb. of anhydrous ammonia; ¾ lb. of nitrous oxide; or 1¼ lb. of sulphur dioxide respectively.

6. Cylinders must be carefully handled, and must not be exposed to the rays of the sun, nor to the heat of a fire, stove, or other source of heat.

GRAPHITE PRODUCTION OF THE UNITED STATES.

U.S. Geological Survey, 1905.

The U.S. Geological Survey reports that the value of Acheson graphite produced in 1904 was 217,790 dols., while the total graphite mined amounted to 341,372 dols., of which amount New York State produced 119,509 dols. worth. The International Acheson Graphite Co. has recently doubled the capacity of its graphite plant, and has contracted with the Niagara Falls Power Co. for another 1000 h.p. of electrical energy, in addition to the 1000 h.p. previously used.

X.—METALLURGY.

IRON TRADE STATISTICS AND COAL OUTPUT OF SWEDEN FOR 1904.

Ed. of Trade J., Oct. 12, 1905.

The following table, showing the production of iron ore, pig iron, &c., in Sweden in 1904, with comparative figures for 1903, is based on official statistics recently published:—

	1903.	1904
	Metric tons.	Metric tons.
Iron ore	3,677,841	4,084,647
Pig iron	506,825	528,525
Blooms from pig iron in charcoal hearths	192,342	189,246
Bessemer ingots and castings	84,229	78,577
Open-hearth ingots and castings	232,878	252,832
Crucible	1,105	1,162
Iron and steel bars	178,538	181,775
Wire rods, iron and steel bands and rods	106,628	102,976

The output of coal in 1904 was 320,981 metric tons, as compared with 320,390 tons in 1903.

XIV.—TANNING; LEATHER; GLUE, Etc.

TANNERIES IN JAPAN.

Cham. of Com. J., Oct. 1905.

In the great Japanese industrial centre, Osaka, there are nearly 50 tanneries, almost all of small importance, employing 1150 workmen and 360 women. These tanneries deal annually with hides to the value of about 766,000 yen,* of which 727,000 yen represent large ox-hides. The hides are almost exclusively of Japanese origin, chiefly from the slaughter-houses of Osaka and Kobe. The price of the hides has risen recently to 12 to 13 yen each. For the tannage oak bark from the islands of Shikoku and Hokkaido is employed, but tanning materials from America are also imported. Osaka also possesses a large manufactory of machine belting, which has existed for twenty years and uses European machinery. The raw material comes principally from Germany, for the Japanese hides are not suitable for this manufacture. This factory has produced during one year about 600,000 yen of merchandise, of which 60,000 yen were exported to China and Corea. About 150 hands, working 10 hours a day, are employed all the year round.

XVII.—BREWING, WINES, SPIRITS, Etc.

SPIRIT TAXATION LAW IN ITALY.

Ed. of Trade J., Oct. 12, 1905.

The Italian "Bollettino di Legislazione e Statistica Doganale e Commerciale" for July, contains the text of an

* Ten yen equals approximately 12.

Italian Law, dated the 29th June, 1905, modifying various provisions of the Spirit Taxation Law of 30th January, 1896.

Article 7 of the present Law abolishes the special tax of 15 centesimi per degree and per hectol. imposed, by the Law of 22nd March, 1903, on spirit derived from non-vinous products, denatured and intended for lighting, heating, motive, or other industrial purposes.

By Article 8 of the Law the manufacturing tax on spirits, other than adulterated spirits destined exclusively for industrial purposes, is increased by 10 centesimi per degree and per hectol. The countervailing surtaxes on imported spirits, and on products containing spirits or prepared therewith, are consequently increased in proportion, and are now as follows:—

	Rate of Surtax.	
	Lire.	Cts.
Spirits, other than adulterated—spirits intended exclusively for industrial purposes		
Per degree, per hectol.	2	00
Ether and chloroform	4	66½
Spirituous essences of rum or cognac; and other essences containing spirit	1	13½
Alcoholic perfumery	1	60
Spirit varnish	1	33½
Medicinal preparations, compound medicines, and chemical products not specially mentioned containing spirit or in the manufacture of which spirit has been used	Surtax, at above rate, on spirits contained or used in their manufacture.	

* Without deduction of weight for the immediate recipient.

Patent List.

N.B.—In these lists, [A.] means "Application for Patent," and [C.S.] "Complete Specification Accepted."

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

- [A.] 20,144. Schumacher. Device for mixing liquids.* Oct. 5.
 „ 20,318. Brown. Regenerative furnaces.* Oct. 7
 „ 20,431. Snell. Apparatus for compressing gas or air. Oct. 10.
 „ 20,697. Kestner. Machine for atomizing liquids Oct. 12.
 „ 20,752. Ostertag. Drying furnaces.* Oct. 13.
 „ 20,808. Pickering (Dixon). See under XVI.
 „ 20,865. Trent. Agitating or mixing apparatus.* Oct. 14.
 „ 20,866. Trent. Filters.* Oct. 15.
 [C.S.] 20,938 (1904). Shiels. Apparatus for heating, condensing, evaporating, &c. Oct. 15.
 „ 23,983 (1904). Ray. Process of and apparatus for continuous distillation. Oct. 18.
 „ 25,832 (1904). Eldred. Reverberating furnaces. Oct. 11.
 „ 1304 (1905). Ter Meer. Centrifugal separating machine. Oct. 11.

- [C.S.] 2795 (1905). Mitchell. Apparatus for generating steam from hot slag. Oct. 11.
- " 5458 (1905). Hurrell and Houze. *See under VIII.*
- " 10,538 (1905). Seitz. Filters. Oct. 18.
- " 11,875 (1905). Hawkes and Klepetko. Water jackets for cupola, blast, and similar furnaces. Oct. 11.
- " 17,946 (1905). Clamond. Method of and apparatus for separating mixed gases. Oct. 18.

II.—FUEL, GAS, AND LIGHT.

- [A.] 19,995. Hutmacher. Carburation of gases.* Oct. 3.
- " 20,175. Just, Hanaman, Landesberger, Salzmann, and Verein. Electricitäts A.-G. Manufacture of incandescing bodies for electric incandescence lamps.* Oct. 5.
- " 20,330. British Thomson-Houston Co., Ltd. (Allgem. Elektricitäts-Ges.). Arc lamp electrodes. Oct. 9.
- " 20,360. O'Sullivan-Beare. Process for preparing peat for use as fuel, peat moss, &c. Oct. 9.
- " 20,445. Wesselsky. Gas generators.* Oct. 10.
- " 20,783. Bickerton, Bradley and Clerk. Gas producers. Oct. 13.
- [C.S.] 21,408 (1904). Perrier. Production of gas by the combination of compressed air with petroleum. Oct. 11.
- " 21,755 (1904). Márton. Manufacture of fuel and other briquettes. Oct. 18.
- " 25,578 (1904). Armstrong, Whitworth and Co., Orde and Sodeau. Combustion of liquid fuel. Oct. 18.
- " 25,879 (1904). Wilton. *See under III.*
- " 27,571 (1904). Hall Brown. Gas producers. Oct. 11.
- " 28,295 (1904). Thorneycroft, and J. I. Thorneycroft and Co. Purifying the gas from gas producers, blast furnaces, &c. Oct. 11.
- " 28,811 (1904). Koppers. Gas furnaces or coke ovens. Oct. 11.
- " 347 (1905). Middleton. Agglutinants for use in solidifying pressed fuel. Oct. 18.
- " 10,706 (1905). Fichet and Heurtey. Gas producers. Oct. 18.
- " 16,993 (1905). Towns. Purifier for gases. Oct. 18.
- " 11,751 (1905). Moores and Bailey. Material for use in manufacturing air gas. Oct. 11.
- " 14,090 (1905). Towns. Gas producers. Oct. 11.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

- [A.] 19,988. Dreyman. Conversion of unsaturated into saturated compounds.* Oct. 3.
- " 20,448. Daum and Co., and Thyarks. Process for the incorporation of petroleum or mineral oil in soaps. Oct. 10.
- [C.S.] 23,727 (1904). Kuess. Process for transforming into soap mineral oils in general and petroleum in particular. Oct. 11.

- [C.S.] 25,879 (1904). Wilton. Distillation especially of tars or tarry products and for use in the manufacture of carburetted water gas and like processes. Oct. 18.

IV.—COLOURING MATTERS AND DYE STUFFS.

- [A.] 20,359. Newton (Bayer und Co.). Manufacture of a new dyestuff of the anthraquinone series and of intermediate products. Oct. 9.
- " 20,780. Abel (Akt.-Ges. f. Anilinfabr.). Manufacture of amidosulphonic acids of phenyl-1,2-naphthimidazole and intermediate products. Oct. 13.
- [C.S.] 26,345 (1904). Holliday and Sons, Turner and Dean. Black colouring matters containing sulphur. Oct. 11.
- " 26,361 (1904). Ransford (Cassella und Co.). Manufacture of benzene derivatives and dye-stuffs therefrom. Oct. 11.
- " 26,477 (1904). Abel (Akt.-Ges. f. Anilinfabr.). Manufacture of a yellow sulphurised dyestuff. Oct. 11.
- " 27,001 (1904). Abel (Akt.-Ges. f. Anilinfabr.). Manufacture of new sulphurised dyestuffs. Oct. 18.
- " 27,092 (1904). Abel (Akt.-Ges. f. Anilinfabr.). *See under XIII.A.*
- " 27,093 (1904). Abel (Akt.-Ges. f. Anilinfabr.). *See under XIII.A.*
- " 27,094 (1904). Abel (Akt.-Ges. f. Anilinfabr.). *See under XIII.A.*
- " 27,292 (1904). Abel (Akt.-Ges. f. Anilinfabr.). Manufacture of sulphurised dyestuffs and of a parent material therefor. Oct. 18.
- " 28,593 (1904). Johnson (Badische Anilin und Soda Fabrik). Manufacture of new colouring matters of the anthracene series. Oct. 18.
- " 28,734 (1904). Newton (Bayer und Co.). Manufacture of a dyestuff of the anthracene series. Oct. 11.
- " 1062 (1905). Newton (Bayer und Co.). Manufacture of oxyanthraquinones. Oct. 11.
- " 5572 (1905). Ellis (Chem. Fabr. vorm. Sandoz). Manufacture of yellow sulphur dyes. Oct. 18.

V.—PREPARING, BLEACHING, DYEING, PRINTING AND FINISHING TEXTILES, YARNS, AND FIBRES.

- [A.] 20,011. Waidmann. Machines for dyeing yarns in hanks. Oct. 3.
- " 20,218. Textile Fibres, Ltd., and Tickle. Treating reën, ramie, or china grass, flax and similar fibres. Oct. 6.
- " 20,220. Hanitzsch. Production of effects or designs on paper, textile fabrics or the like.* Oct. 6.
- " 20,268. Ainley. Machine for drying, tentering and steam blowing fabrics. Oct. 7.
- [C.S.] 27,871 (1904). Inray (Meister, Lucius und Brüning). Method of and apparatus for distributing dyestuffs on fabrics, warps or the like. Oct. 18.

- [C.S.] 20,130 (1904). Adam (Erste Triester-Reisschäl-Fabriks A.-G.). Manufacture of sizing or finishing media. Oct. 11.
- .. 1281 (1905). Bloxam (Verein. Glanzstoff-Fabrik A.-G.). Manufacture of threads and films of cellulose. Oct. 11.

VI.—COLOURING WOOD, LEATHER, PAPER, Etc.

- [A.] 20,220. Hanitzsch. *See under V.*

VII.—ACIDS, ALKALIS, AND SALTS.

- [A.] 19,839. Worsey and Hoal. *See under XIII A.*
- .. 19,986. Johnson (Chem. Fabr. Griesheim-Elektron). Concentration of dilute nitric acid. Oct. 3.
- .. 20,312. Moharrem. Preparation of carbeneum from the carbonic acid of all carbonates. Oct. 7.
- .. 20,454. Reaney. Process for hydrating lime.* Oct. 10.
- .. 20,837. Grossmann. Method of manufacturing sulphate of ammonia. Oct. 14.
- [C.S.] 21,393 (1904). Souheur. Preparation of briquettes of arsenious acid. Oct. 11.
- .. 6759 (1905). Westhauser. Manufacture of hydrochloric and hydrobromic acid. Oct. 11.

VIII.—GLASS, POTTERY, AND ENAMELS.

- [C.S.] 5458 (1905). Hurre and Houze. Regenerative furnaces for the manufacture of glass and for other purposes where a high temperature is required. Oct. 11.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

- [A.] 20,070 Thom. Artificial stone. Oct. 4.
- .. 20,296. Baur. Machinery for preparing or treating loam clay and the like. [Swiss Appl., Dec. 3, 1904.]* Oct. 7.
- .. 20,868. Ford. Manufacture of artificial stone. Oct. 14.
- [C.S.] 25,837 (1904). Eldred. Method and means for burning cement. Oct. 11.
- .. 26,286 (1904). Constable and Hart. Manufacture of tarred paving, macadam and the like. Oct. 11.

X.—METALLURGY.

- [A.] 19,860. Blackmore and Howard. Treatment of complex ores containing lead, zinc and other sulphides. Oct. 2.
- .. 19,892. Siemens und Halske A.-G. Process for hardening tantalum metal. [Ger. Appl., Oct. 13, 1904.]* Oct. 2.
- .. 19,941. Blood. Method of utilising iron ore waste in the manufacture of iron and steel. Oct. 3.
- .. 20,004. Goldschmidt and Weil. Method of manufacturing metals according to the aluminothermic process. Oct. 3.

- [A.] 20,322. Wolf. Separation of metals from their ores. Oct. 7.
- .. 20,380. Bousfield (Mackay and Beckwith). Treatment of sulphide ores.* Oct. 9.
- .. 20,884. Kühne. Process for the production or isolation of metals, metalloids, or their alloys.* Oct. 14.

- [C.S.] 22,422 (1904). Auchinachie. Process of obtaining metallic vanadium from its ores or other vanadium compounds. Oct. 18.
- .. 26,881 (1904). Perret. Method of treating ores of vanadium. Oct. 18.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

- [A.] 20,024. Harris. Electro-deposition apparatus. Oct. 4.
- .. 20,107. Swan and Hyde. Coating metals with metals. Oct. 5.
- .. 20,217. Vareille. Apparatus for the electrolysis of water.* Oct. 6.
- .. 20,500. Hatfield, and The Reason Manufacturing Co., Ltd. Mercury electrolytes. Oct. 10.
- .. 20,737. Markus, and The Barnwell Machine Co., Ltd. Insulating materials for covering electric cables. Oct. 13.
- .. 20,770. Hatfield, and The Reason Manufacturing Co., Ltd. Cathodes. Oct. 13.
- [C.S.] 21,562 (1904). Koopman (Townsend). Electrolytic method and apparatus for the production of white lead. Oct. 18.
- .. 23,765 (1904). Rudenick. Insulating material for electro-technical purposes. Oct. 18.
- .. 26,602 (1904). Johnson (Badische Anilin und Soda Fabrik). Apparatus for producing reactions in gases by means of electric arcs. Oct. 11.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

- [A.] 19,988. Dreymann. *See under III.*
- .. 20,103. Hine. Soap. Oct. 5.
- .. 20,448. Daum und Co., and Thyarks. *See under III.*
- [C.S.] 21,596 (1904). Bedford, Bedford and Crowther. Process and apparatus for the preparation of soap. Oct. 11.
- .. 23,737 (1904). Kuess. *See under III.*
- .. 29,081 (1904). Holmblad. Candles. Oct. 18.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

(A.)—PIGMENTS, PAINTS.

- [A.] 15,398a. Bennett and Mastin. Manufacture of permanent pigments from glass.* Oct. 14.
- .. 16,490a. Brunet. Manufacture of white antimony pigment. Oct. 13.
- .. 19,839. Worsey and Hoal. Manufacture of zinc white from substances or compounds containing zinc. Oct. 2.
- [C.S.] 21,562 (1904). Koopman (Townsend). *See under XI.*

- [C.S.] 27,092 (1902). Abel (Act.-Ges. f. Anilinfabr.)
Manufacture of orange colour lakes. Oct. 18.
 „ 27,093 (1904). Abel (Act.-Ges. f. Anilinfabr.)
Manufacture of new colour lakes. Oct. 18.
 „ 27,094 (1904). Abel (Act.-Ges. f. Anilinfabr.)
Manufacture of red colour lakes. Oct. 18.

(B).—RESINS, VARNISHES.

- [A.] 20,888. Godfrey, and The Linoleum Manufacturing
Co., Ltd. Manufacture of linoleum. Oct. 14.
 [C.S.] 27,037 (1904). Shaw. Machinery for printing the
pattern on linoleum, oilcloth, and like materials.
Oct. 18.

(C).—INDIA-RUBBER.

- [A.] 20,606. Wilderman. Technical separation of red
rubber into its important and unimportant
parts. Oct. 11.
 „ 20,610. Munby. Treatment of india-rubber.
Oct. 11.
 „ 20,709. Scott, Dagnall and Thomas. Substance
similar to india-rubber and process for manu-
facturing the same. Oct. 13.
 [C.S.] 24,966 (1904). Jacobs, Jacobs and Brockwell.
India-rubber substitute. Oct. 18.

XIV.—TANNING, LEATHER, GLUE, SIZE, ETC.

- [C.S.] 26,778 (1904). Payne. Tanning and the treat-
ment of waste tanning materials and liquors.
Oct. 18.
 „ 27,425 (1904). Hilbert. Process of and apparatus
for manufacturing glue and gelatin. Oct. 18.
 „ 29,130 (1904). Adam (Erste Triester-Reisschäl-
Fabriks A.-G.). *See under V.*

XV.—MANURES, ETC.

- [A.] 20,228. Norman. Manures for horticultural and
agricultural purposes. Oct. 6.

XVI.—SUGAR, STARCH, GUM, ETC.

- [A.] 20,808. Pickering (Dixon). Centrifugal separator
for the treatment of sugar and other materials.
Oct. 14.

XVII.—BREWING, WINES, SPIRITS, ETC.

- [A.] 20,246. Chew, and H. J. West and Co., Ltd. Pro-
duction of non-deposit beer and apparatus
therefor. Oct. 6.
 „ 20,876. Hunt. Treatment of fusel oil or malt or
other spirits for maturing the same, and rendering
them more commercially valuable. Oct. 14.
 [C.S.] 26,698 (1904). Board and Board. Process of
fermentation. Oct. 11.
 „ 11,147 (1905). Barker (Ronnberg und Co.). Manu-
facture of a product which enables beer to be
hopped in a rational and economical manner.
Oct. 18.

XVIII.—FOODS; SANITATION, WATER
PURIFICATION; & DISINFECTANTS.

(A).—FOODS.

- [A.] 20,306. Gratz. Process for aerating and cleaning
flour and the like.* Oct. 7.
 „ 20,488. Müller. Method of bleaching flour and
the like. Oct. 10.
 „ 20,755. Héritte. Alimentary extracts of blood.
Oct. 13.
 [C.S.] 9457 (1905). James (Organose Co.). Manufacture
of a food product. Oct. 11.

(B).—SANITATION; WATER PURIFICATION.

- [A.] 20,080. West. Water softening or purifying
apparatus. Oct. 4.
 „ 20,234. Cameron and Commn. Treatment of
sewage. Oct. 6.
 „ 20,750. Kestner. Process for the purification of
water, sewage effluent and the like, and apparatus
therefor. Oct. 13.
 [C.S.] 5537 (1905). Stephenson. Apparatus for purifying
water or other liquids. Oct. 11.

(C).—DISINFECTANTS.

- [C.S.] 23,463 (1904). Hawliczek. Disinfectant and
detergent compounds. Oct. 18.
 „ 25,308 (1904). Gauthier. Manufacture of a gas
for disinfecting purposes. Oct. 18.
 „ 5278 (1905). Illingworth. Means for disinfecting.
Oct. 18.

XIX.—PAPER, PASTEBOARD, ETC.

- [A.] 20,802. Baker and Lockett. Paper making
machines. Oct. 14.
 [C.S.] 9698 (1905). Kuess. Transformation of alfa and
similar plants into paper pulp or textile fibres.
Oct. 11.
 „ 12,523 (1905). Erkens. Paper making machines.
Oct. 18.

XX.—FINE CHEMICALS, ALKALOIDS,
ESSENCES AND EXTRACTS.

- [A.] 19,988. Dreyman. *See under III.*
 [C.S.] 26,779 (1904). Zimmermann (Schering). Manu-
facture of camphor. Oct. 11.
 „ 4564 (1905). Abel (Act.-Ges. f. Anilinfabr.)
Manufacture of dialkyl-derivatives of malonyl-*p*-
phenetide. Oct. 18.
 „ 4959 (1905). Abel (Act.-Ges. f. Anilinfabr.) Manu-
facture of soluble compounds of theobromine.
Oct. 11.
 „ 14,316 (1905). Mettler. Manufacture of alcohols
and ethers by the reduction of aromatic esters.
Oct. 11.
 „ 18,674 (1905). Mettler. Manufacture of aromatic
alcohols. Oct. 11.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

- [A.] 19,850. Poulsen. Self-toning photographic paper.* Oct. 2.
- „ 19,885. Kelly and Bentham. Developing and fixing photographic negatives or positives. Oct. 2.
- „ 20,372. Neue Photographische Ges., A.-G. Reproduction of pictures, &c., with the aid of catalysis. [Ger. Appl., Oct. 13, 1904.]* Oct. 9.
- „ 20,662. Powrie. Colour photography.* Oct. 12.
- [C.S.] 21,210 (1904). Brasseur. Polychrome photographs. Oct. 11.
- „ 24,290 (1904). Koppmann. Process for producing coloured photographs. Oct. 11.
- „ 9036 (1905). Mertens. Photographically copying designs for the production of printing surfaces. Oct. 11.

[C.S.] 17,303 (1905). Hoffsummer. Manufacture of photographic papers. Oct. 11.

XXII.—EXPLOSIVES, MATCHES, Etc.

- [A.] 20,310. Reese. Process of making nitroglycerine.* Oct. 7.
- „ 20,353. Bokmayer and Swoboda. Match compositions.* Oct. 9.
- „ 20,706. Arnold, Scott and Fox. Recovery of acetone or other volatile substance used in the manufacture of cordite or other material containing nitrocellulose or rubber. Oct. 12.

XXIII.—GENERAL ANALYTICAL CHEMISTRY.

[C.S.] 15,160 (1905). König. Titration apparatus. Oct. 11.

Official Notices.

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

SIXTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY, ROME, 1906.

The Sixth International Congress of Applied Chemistry will be held in Rome in April, 1906, during Easter week. All communications should be addressed to the President, Prof. E. Paternò, Via Panisperna, 89 Rome.

Foreign and Colonial members are reminded that the subscription of 25s. for 1906, payable on January 1st next, should be sent in good time to the Hon. Treasurer (Mr. Samuel Hall) in order to ensure continuity in the receipt of the Society's Journal. Any changes of address for the new List of Members now in course of preparation should reach the General Secretary not later than January 31st, 1906.

Changes of Address.

When notifying new addresses, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is also to be avoided as tending to create confusion. When sending subscriptions, the use of the form attached to the application helps in the verification of addresses, on which the safe delivery of the Journal depends.

MR. J. M. C. PATON IN THE CHAIR.

STRYCHNINE TANNATE AND ITS USE IN THE ANALYSIS OF TANNING MATERIALS.

BY S. P. TROTMAN, M.A., F.I.C., AND J. E. HACKFORD.

Although the hide powder method of analysing tanning materials has held the field so long, and has served so well as an illustration of the way in which difficulties of analysis can be overcome, yet it has never been pretended that it is perfect as an analytical method. In that it has enabled chemists to agree approximately in their results it has been exceedingly useful, but as is well-known to those who have to use the process, this agree-

ment can only be obtained by rigidly following out the prescribed conditions. Moreover, when one has taken the utmost care in the analysis, one is still at the mercy of the hide power, and whenever disagreement occurs between two chemists it can often be traced to this cause. The increasing and, at times, almost unsurmountable difficulty of obtaining a satisfactory supply of hide power is so great, that a method which eliminates this substance would be welcomed by everyone, and for a long time chemists have been trying to arrive at some such method.

We have ourselves made experiments with at least twelve different methods, but which have had to be thrown aside.

The method suggested by Parker and Payne, namely, precipitation of tannic acid by means of collin, was in many ways a considerable advance, but was not ideal because it was an indirect process, and, moreover, as shown by Wood and Trotman* the precipitating reagent has not a constant composition, and the constitution of the precipitated products is practically unknown. The chief claim which the collin method has is that, unlike hide powder, it does not co-estimate gallic acid.

An ideal method must be one in which a known compound of tannic acid is produced and weighed, and with this end in view we have for a long time been making experiments which, we venture to think, will go some way towards solving the problem. During the course of these experiments it became accidentally known to one of us that Drs. Parker and Casaburi were also working at the same subject, and a notification of this fact has since appeared in the "Collegium." We feel that the field is so wide and the subject so important that there is room for all, and trust that our joint efforts will assist in placing the analysis of tanning compounds above the reproach of being merely empirical. A brief account may be given of the experiments that have led up to the method which we now suggest.

(1) Experiments with collin solution show that there are objections to its adoption as a standard method, for the following, among other reasons:—

- It is not constant in composition.
- It possesses no advantage over commercial peptone, or even over a dilute solution of albumoses or pure gelatine (except in keeping properties) and very little advantage over the collagens.

The following experiments prove this point, and are enumerated in the table given below:—

Reagent employed.	Quantity used, c.c.	Strength, per cent.	Nature of ppt. on adding 0.0001 grm. tannic acid.	Effect on adding 1 c.c. 50 per cent. acetic acid	Effect on adding excess of acid.
(1) Collagen	10	1	slight precipitate	dissolves	dissolves
(2) Albumoses	10	1	slightly heavier than (1)	no action	ditto
(3) Commercial peptones ..	10	1	heavy	no action	dissolves with difficulty
(4) Collin	10	1	not so heavy as (3)	little action, if any	dissolves more easily than (3)
(1) Collagen	10	5	no ppt.	no action	no action
(2) Albumoses	10	5	no ppt.	ditto	ditto
(3) Commercial peptones ..	10	5	marked ppt.	ditto	dissolves
(4) Collin	10	5	ditto, and of same bulk	ditto	dissolves more easily than (3)

From this it is seen that so far as sensitiveness is concerned, collin is not equal to commercial peptones, while it is very little superior to collagen and albumoses, if the latter be in a weak solution (1 per cent.). It is superior to the latter two if the strength of the solutions be greater than that mentioned.

Messrs. Parker and Payne also state the sensitivity of the collin solution to be increased by the addition of acetic acid. We point out, however, that with or without acid it is not equivalent to commercial peptones, while, if a slight excess of acid be added, the precipitate redissolves, as it also does in the case of collagens, albumoses and peptones. Without the addition of more acetic acid, we would point out that the difference between collin solution and commercial peptones is that collin = peptones + sodium acetate - calcium salts, and the difference in results given by collin is evidently due to the presence of sodium acetate.

(2) Many experiments were tried with metallic salts, but it appeared to be almost impossible to obtain complete precipitation, since the precipitate is soluble in the acid liberated. Thus CuSO_4 gives a ppt. with tannic acid which is soluble in sulphuric acid and that given by lead acetate is soluble in acetic acid. It was found difficult to make alkaline and so neutralise the acid liberated, for the alkali decomposes a tannic acid solution, causing it to turn brown, since tannic acid is very readily oxidised.

In passing we noted that tannic in solution may be estimated by means of Fehling solution, but that gallic acid is also simultaneously decomposed.

(3) *Experiments with Organic Bases.*—As a result of the experiments with metallic salts we tried bases, for here there is no acid to be liberated, while if an acid other than tannic be present it will be neutralised if the base be present in excess. By this means foreign acids which might affect the insolubility of the precipitate are removed.

A great many bases were tried, including phenyl hydrazine and several primary and secondary amines with more or less satisfactory results, and to which we hope to return in a later paper.

Passing from these to the more complicated bases, namely, alkaloids which are tertiary amines, we arrived at what appeared to be a solution of the difficulty. It is known that the alkaloids combine with tannic acid, giving more or less insoluble tannates, but little attention appears to have been paid to these compounds. The tannate is produced by precipitation with free alkaloid, the excess of which neutralises any other free acid present forming soluble compounds.

Several alkaloids were tried, but strychnine finally made use of, since it is cheap, does not precipitate gallic acid, and its tannate is highly insoluble in water and fairly easily manipulated.

Experiments with Strychnine and pure Tannic Acid.—When strychnine or its salts are added to a solution containing tannic acid, a white flocculent precipitate is produced. Its insolubility is so great that one part in 10,000 of tannic acid may be readily detected, when the base itself is employed.

As we were unable to find any full description of this compound, it seemed advisable to us to make a careful study of it, and determine its composition. A considerable quantity of the compound was prepared and

purified by decantation. It was then filtered through a porous plate and thoroughly washed with water, alcohol and chloroform, and dried in a vacuum. The compound cannot be crystallised and is decomposed when heated, so that its m. pt. cannot be determined. When dry it is a white amorphous powder which contains no water. Upon combustion, it gave the following figures:—

C, 63.80 : H, 4.80 : N, 4.25:

theory for $\text{C}_{21}\text{H}_{22}\text{N}_2\text{O}_2$, $\text{C}_{14}\text{H}_{10}\text{O}_9$:—

C, 64.02: H, 4.87: N, 4.27.

These figures leave little room for doubt: but further confirmatory evidence was obtained in the following way:—

The weight of the precipitate produced from a known quantity of pure tannic acid with excess of strychnine was determined with great care. Twelve separate experiments gave practically identical results, and proved conclusively that the acid and base combine in the proportion of 1 mol. of each, and, further, that the compound has

* Notes on collin. This J., 1904, pp. 1071-1072.

a constant composition when thrown down in the presence of excess of the base.

A known quantity of strychnine having been used, the unused portion was estimated, and again found to agree.

The following are details of the method employed in obtaining the precipitate, and since this is that which is used in the case of tanning materials a short description may be of service:—0.125 grms. of pure tannic acid were dissolved in 50 c.c. of water in a 250 c.c. flask, and cooled. 0.25 grms. of strychnine are now dissolved in 50 c.c. of alcohol and diluted with water until its volume is nearly 200 c.c., cooled and added to the tannic acid solution. The mixture is now made up to 250 c.c., thoroughly shaken, and filtered through a Gooch crucible, dried in a vacuum and weighed.

Using 0.125 grms. of tannic acid the theoretical weight of the precipitate is 0.2546 grms., while the mean result of 12 experiments gives 0.2540 grms., the variation being very small. The residual alkaloid was, in each case, estimated as a check. These results conclusively prove that the formula of the precipitate is $C_{21}H_{22}N_2O_2 \cdot C_{14}H_{10}O_9$, when dry.

Analysis of Tanning Material.—These may be extracted in the ordinary way, but as the result of many experiments, we find the process of extraction shortened and made more complete by using alcohol and a Soxhlet extractor.

F. P. Veitch * records the real and imaginary objections to the extraction of tanning materials by the different methods, using water as the extracting liquid. By the use of alcohol all possible objections are overcome, such as hydrolysis of tannic acid, &c. This is conclusively proved in the case of a sample of lentisco, which, upon immediate analysis when extracted by alcohol, gave a result of 5.08 per cent. tanning matters. After boiling for a fortnight 5.00 per cent. tannins were found, thus showing that no hydrolysis had taken place.

To avoid the use of a water bath, or a direct flame, a modification of the electrical heaters (proposed by us at a previous meeting, this J., 1904, 1137) is used. The alcohol is placed in a flask with a re-entering bottom, in which is fitted a cylindrical electric lamp, the filaments of which are similar to those employed in electric radiators. The lamp is raised or lowered as may be necessary. The extraction will be complete when the spirit comes from the Soxhlet extractor colorless, and generally does not require more than half an hour, the advantage being that the alcohol may be made to boil at whatever rate one pleases, without running the risk of the dissolved matter being left above the surface of the alcohol in a dried and possibly burnt condition. The quantity of material extracted should contain about 0.5 gm. tanning material. This is placed in the tube having a perforated bottom, and is prevented from falling through by a small plug of cotton wool, while another small plug is placed above, to prevent particles flowing over the top. (See diagram.)

The solvent is now evaporated to about 50 c.c., then poured into a 100 c.c. flask, and made up to the mark with water. This will cause the precipitation of resins and similar bodies which have been extracted by the alcohol. These are filtered through a dry Gooch crucible, and the tannic acid is estimated in 25 of the filtrate. A further 25 or 50 c.c. is evaporated to dryness, and the residue weighed to determine the non-soluble tannins. The tannic acid in the filtrate is estimated as follows:—25 c.c. of the extract are placed in a 250 c.c. flask and diluted with water. 0.25 gm. of strychnine are then weighed out and dissolved in about 50 c.c. of alcohol. To this an equal volume of water is added, the mixture cooled and added to the tannic acid, the contents of the flask being diluted to the mark, and thoroughly mixed. If the precipitation be not carried out in the above manner, it is found that the strychnine tannate will not come down in a sufficiently flocculent form, and will be difficult to filter.

The contents of the flask are now filtered through a weighed Gooch crucible. The crucible used has a diameter of from 1 to 2 ins. at the bottom, and may be made of platinum or porcelain. Having fixed it to the filter pump, a thin mat of asbestos pulp is prepared in the usual way,

dried over the blowpipe flame and weighed. The tannates, after filtration, are partly dried by means of a current of air, the dehydration being completed in a vacuum oven, by which decomposition is avoided, this occasionally taking place if dried in an air or water oven.

A very simple form of laboratory vacuum oven may be made as follows:—A bell-jar fitted with a rubber bung stands on a ground-glass plate. Through the bung passes an electric wire from the main supply, and which is internally connected with a lamp, by which the temperature of the bell-jar is raised to about 60° C.

The results attained by this method of estimation are quite consistent. The same sumach was analysed on three separate days, the results being shown in the following table:—

Weight of sumach used.	Percentage of tanning matter estimated.	Percentage of soluble non-tannins estimated.
(1) 2.5 grms.	23.44	17.84
(2) 2.5 „	23.56	17.52
(3) 5.0 „	23.752	17.92

The following table shows a few results obtained from the commoner tanning materials, and proves that the figures obtained by this method do not necessarily agree with those from the hide powder method, showing that the latter absorbs many substances other than tannic acid. This has already been pointed out by Parker and Payne, but apparently even collin, although incapable of precipitating gallic acid, still combines with organic substances which are unaffected by strychnine. These results are embodied in the following table. It will be seen that they are, as might be expected, much lower than those obtained by the bell filter, while the soluble non-tannins are, as a rule, higher than those obtained by either Procter or Parker, the difference being probably due to colouring matter which is not estimated at all by strychnine.

It is, of course, obvious that there remains much to be done in connection with the various tannic acids which occur in the different tanning materials, more information being required as to their power of combining with alkaloids and their actual value in the tan-yard. This investigation is already in hand.

	Percentage of tanning matter by Procter.	Soluble non-tannin by Procter.	Total solids by Procter.	Tanning matter by Trotman and Hackford.	Soluble non-tannin by Trotman and Hackford.	Total solids by Trotman and Hackford.

DISCUSSION.

Mr. J. T. WOOD mentioned as a singular coincidence that Messrs. Trotman and Hackford and Dr. Parker and Mr. Payne hit upon the idea of using alkaloids for the precipitation of tannin independently of each other. The figures quoted required digesting before one could criticise them properly. The extraction by alcohol did not take out the same amount of matter as extraction by water, as one would naturally expect. He noticed that in the case of sumach the difference in total solids as determined by Procter's method, and the total solids as determined by Trotman and Hackford's method, was 0.72 in favour of alcohol.

In the case of gambier the difference was 2.24 less by alcohol than by water, but in myrobalans 16.36 less. He concluded that the tannin in sumach was nearly pure gallo-tannic acid. Myrobalans tannin appeared to be a mixture of gallo-tannic acid and another tannic acid. Had Mr. Trotman tried pure tannins other than gallo-

tannic acid? If so, it would be interesting to know how they behaved. The resemblance between the values given by collin precipitation and the strychnine precipitate was remarkable. He suggested that figures should be given showing results from other tannins which had been isolated in a pure state.

Prof. F. STANLEY KIPPING said it appeared to him that, from a chemical point of view, Messrs. Trotman and Hackford had made a distinct step in advance as this was the first time that the matter had been worked out on a strictly scientific basis. Instead of using as reagent a mixture of unknown compounds they had used a pure and definite base, whose purity could be guaranteed. He would like to know if, instead of using strychnine, the authors had made experiments with amido acids, or with compounds that approximated closely to those which absorbed tannic acid in the hide powder. What was the difference between the constituents taken out by the strychnine and by the hide powder? Had they tried the effect of adding hide powder after the gallo-tannic acid had been removed by strychnine, and, if so, what sort of a product had they got? If not had they added any other bases to the filtrate after precipitating the gallo-tannic acid?

Dr. A. TURNBULL said that Messrs. Trotman and Hackford appeared to be working on correct lines using a pure chemical substance as precipitant and estimating the tanning matters from the weight of the precipitate. From the results it was clear that only certain tannins were precipitated by strychnine. This was interesting from a chemical point of view, but for purposes of trade it would be necessary to get at the full added weight which went to make leather. He also would be glad to be free from having to use hide powder in tannin analysis, but, at the same time, he felt that hide powder was not altogether to blame for want of concordance amongst the various chemists, as some of this was undoubtedly due to minute differences in manipulation. There seemed to be no advantage, but rather many disadvantages, in extracting tannin materials by means of alcohol in place of water.

Dr. J. GORDON PARKER said the paper could not be digested in one night without a careful consideration of the figures. It was true that he had been working on similar lines to Messrs. Trotman and Hackford, but, unfortunately, he had not been able to complete his

experiments. He and his colleague, Mr. Payne, had discarded strychnine because it could not be titrated. They got better results with quimidine acetate, brucine and other materials, but were not yet ready with their results. He did not like the idea of extracting tanning materials with alcohol. So little was known as to how tannin existed whether in combination or in a free state. They could not get an equal extraction with alcohol and water. When they got it with alcohol they threw out some tannins which existed in combination with soluble compounds.

Mr. E. M. PAYNE objected to the use of any method which could not be used in an acid solution, since, in the tan-yard, liquors were almost invariably strongly acid. He further objected to the statement that the collin method would not estimate gallic acid. He claimed that it did, and that its estimation was of as much importance as that of the gallo-tannic acid. Tannate of strychnine had been found by Dr. Parker and himself to be soluble in acetic acid, and he thought this would be an objection.

Mr. S. R. TROTMAN, in reply, said that they were quite well aware of the solubility of the tannates of strychnine and other alkaloids in acetic acid, and for this reason they preferred to use the alkaloid itself as recommended in the paper. The previous neutralisation of the tannic acid before precipitation was practically very difficult although theoretically possible, since the tannins were so readily oxidised. He disagreed with Mr. Payne when he said that the collin method was capable of estimating gallic acid. On the contrary he thought that great claim was made for this method largely because it did not estimate gallic acid except by inference, which could also be done by means of strychnine. It appeared to him that a method of this sort must be an advance towards the discovery of a perfect method, since it was an attempt to place the estimation of tannin upon a purely scientific basis, and one could not too strictly emphasise the importance of a direct method. They had also tried titration, but found volumetric methods unsuitable to strychnine. With reference to the delicacy of the reaction they had never failed to be able to detect tannic acid by means of strychnine in a solution which gave a positive reaction

with collin. They did not, of course, at this stage, put the method forward as one to replace the hide powder. They had tried certain amido compounds but hitherto unsuccessfully. If hide-powder were added after the gallo-tannic acid had been removed by strychnine, gallic acid would, at any rate, be removed. They had used collin for this purpose and found that strychnine removed practically the same constituent.

With reference to the extraction of tanning materials by means of alcohol they agreed that it was unsuitable for some materials, but there seemed to be no reason why it should not be used for others. Most of the figures given in their table had been obtained from alcoholic extracts, and they agreed in most cases fairly well with those from the aqueous extract. In some cases the enormous shortening of time would be of considerable advantage. It should be noted that so far as they had gone at present they had only dealt with gallo-tannic acid, which was readily soluble in alcohol. Experiments with other forms of tannic acid were already in progress, the results of which they hoped to bring before the Society at a future meeting.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—8d. each, to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—1s. each, to the Secretary of the Society.

French.—1 fr. 25 c. each, to Belin et Cie, 56, Rue des Francs-Bourgeois, Paris (3^e).

I.—PLANT, APPARATUS & MACHINERY.

ENGLISH PATENTS.

Separating Machines; Centrifugal. — G. Ter Meer, Hanover, Germany. Eng. Pat. 1304, Jan. 23, 1905. Under Int. Conv., Feb. 16, 1904.

SEE Fr. Pat. 351,143 of 1905; this J., 1905, 835.—T. F. B.

Straining, or Separating Solids from Fluids, more especially intended for Use with Apparatus operated by Water, or other Fluid; Apparatus for. — P. Evans, Philadelphia. Eng. Pat. 11,780, June 5, 1905. Under Int. Conv., June 4, 1904.

The invention relates to methods of straining the water supplied to automatic alarm devices used with sprinklers or other fire-extinguishing apparatus. The water entering the apparatus is caused to impinge at an acute angle or tangentially on to the surface of a wire gauze screen. The water passes through the screen, and any solid matter

that has been stopped by the gauze, is washed off by the inflowing water, and either settles to the bottom of the chamber, or is carried forward into a trap, formed by prolonging the screen beyond the opening through which the strained water passes.—W. H. C.

UNITED STATES PATENT.

Coal, Ores and other Minerals; Method of and Apparatus for Treating — for Draining them of Water. F. Baum, Herne, Germany. U.S. Pat. 801,204, Oct. 10, 1905.

Motive Agents (Alcohol, Hydrocarbons or Mixtures of the two); Method of Increasing the Efficiency of —, by the Addition of Bodies rich in Oxygen. C. H. J. Roth. Fr. Pat. 354,285, May 15, 1905.

THE claim is for the addition of ammonium nitrate to the alcohol, hydrocarbons or mixtures of both used in explosion engines, with the object of increasing the efficiency. An alcoholic solution of ammonium nitrate may be added to the alcohol, &c., before use, or an aqueous solution may be injected into the explosion chamber along with the combustible. Several suitable mixtures are given as examples.—W. H. C.

Condensers, Coolers, &c., employed in Distilling and other Industries; Impts. in —. E. Guillaume. Fr. Pat. 354,402, May 18, 1905.

A WOODEN rod or a metal tube, closed at both ends, is suspended concentrically in each of the tubes of a tubular condenser. The inner rod or tube is of slightly smaller diameter than the condenser tube, thus the cross-sectional area of the space through which the liquid flows is decreased and, if the same volume of liquid is used as in ordinary cases, the rate of flow through the annular space is largely increased, with the result that the condenser or cooler is much more efficient.—W. H. C.

Evaporating in Vacuo: Apparatus for —, with Separate Compartments for Heating and Vaporising. R. Sauerbreay. Fr. Pat. 354,711, May 27, 1905.

SEE Eng. Pat. 10,947 of 1905; this J., 1905, 958.—T. F. B.

II.—FUEL, GAS, AND LIGHT.

Gas; Utilisation of Natural —. Naphtha, 1905, 12, 264. Chem. Rev. Fett- u. Harz-Ind., 1905, 12, 251.

IN Austria, a patent has been taken out by Wolski for the liquefaction of natural gas, and Linde's apparatus has been used for the purpose by Dabrowski in the oil fields of the Carpathian Co. For the liquefaction of this gas, it is sufficient to reduce the pressure from 50 to 5 atmos. The liquefied gas begins to distil at -106°C ., and has thus a higher b.pt. than methane (-162°C .), and a lower one than ethane (-89°C .). The first fraction probably consists, in the main, of methane, the higher b. pt. being due to the presence of other substances. It also contains heavy benzene constituents, which separate in the gas pipes, and form the residue left on the evaporation of the more volatile portions of the liquefied gas. A further advantage of its use is that the vapours of the liquefied product have only a relatively small tension, so that the liquid can be kept and transported in ordinary soda-water siphons. It is particularly suitable for small gas engines, for lighting isolated houses, and as fuel for motor cars, &c. Some notion as to its cost may be formed from the fact that a firm in Augsburg was able to manufacture liquefied coal-gas at a cost of 1.2 mark. per kilo., or 4.5 to 6.5 pfg. for 100 Hefner candles per hour. Since the natural mineral gas is, a by-product, its cost in the condensed form must be much less than this.—C. A. M.

Iron Oxide as a [Gas] Purifying Agent, and its Valuation as a Raw Material and in a Spent Condition. H. L. Greville. J. Gas Lighting, 1905, 91, 750–751.

AFTER discussing the regulations with regard to the removal of sulphur compounds from gas, and describing the usual methods of analysing the raw bog ore (iron oxide) used for this purpose, the author states that there is considerable doubt as to the real composition of hydrated oxide of iron. In a recent commercial case, the seller put forward the formula $\text{Fe}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$, whilst the buyer insisted on the formula $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$ for the substance. The author found that the precipitate produced by ammonia in a solution of ferric chloride, had the composition $2\text{Fe}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$ after being dried at 100°C . Some experiments on natural bog ores dried over sulphuric acid in a desiccator and afterwards exposed to a temperature of 100°C ., showed that the substance contained a

hydrate which was decomposed, at least partially, at a lower temperature than 100°C . Results of quantitative tests showed that natural bog ores contained hydrated ferric oxides which have a higher percentage of combined water than is represented by the formula $2\text{Fe}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$.

For the determination of sulphur in spent oxide, the author introduces 250 grs. of the sample into carbon bisulphide contained in a 250 c.c. flask, having a fairly long neck. After shaking for a short time, the solution is filtered, and 100 c.c. of the filtrate (100 grains of sample) are evaporated to dryness, and the residue of sulphur weighed. This method is much quicker than the usual exhaustion with carbon bisulphide, and is stated to give equally accurate results.—A. S.

Gas; [Cost of] Purification of — from Sulphuretted Hydrogen. T. Holgate. J. Gas Lighting, 1905, 92, 171.

As the result of a complete year's working at the Halifax gas works, using only oxide purification, after the gas had been passed through purified ammoniacal liquor, a net profit of 0.04d. per 1000 cb. ft. of gas sold was realised; as the average of the six lowest costs of purification at other works was 0.23d., this represented, on the quantity of gas sold, a saving of over £900. In six of the last eight years, a profit was made on the oxide section of the purification. The following statement shows the cost of purifying 1000 cb. ft. of gas by oxide, and by lime, and also the net cost of purification during the last eight years:—

Year ended March 31.	Percentage of carburetted Water Gas.	Oxide Purific. cost.	Lime Purific. cost.	Net cost.

—T. F. B.

Acetylene; Dissolved —. Kuchel and E. Bournonville. Engineer, 1905, 100, 381–382.

“DISSOLVED acetylene” consists of acetylene dissolved in acetone under a pressure of several atmospheres, the liquid being absorbed completely by porous material contained in steel cylinders. The maximum pressure employed is 10–12 atmospheres. One volume of acetone holds, at 10 atmospheres, 250 volumes (as measured at the ordinary atmospheric pressure) of acetylene gas, and 300 volumes at 12 atmospheres. The solubility is seriously reduced by impurities in the acetone, especially water; and since a cylinder containing the porous substance is used repeatedly in practice, the capacity in terms of gas gradually decreases. The porous materials at present in use are made either from asbestos and sodium silicate, or from charcoal and a cementing substance, and their porosity is fixed, as accurately as possible, at 80 per cent., i.e., 80 per cent. of their apparent volume consists of interstitial spaces. On being fully saturated with acetylene at 12 atmospheres pressure, 1 volume of acetone expands to about 1.5 volumes; hence, in charging a cylinder, filled with the porous substance, a quantity of acetone little more than one-half the volume of the interstitial space is introduced, the remaining space being available for expansion, and for some free compressed gas. It is found that, as required by theory, the gas from a 12-atmosphere cylinder carries oil, per 1000 litres, the vapour of 60 c.c. (48 grms.) of liquid acetone. In the process of manufacture, washed dried acetylene is passed through a meter, a water-cooled compressor, and a separator (for removing oil carried over from the pump), into the cylinder, which has previously been filled with the porous substance, evacuated, and charged with the necessary quantity of acetone.

From experiments made by Kuchel it appears that a cylinder charged to 12 atmospheres pressure at 20°C .,

could only develop a pressure of about 24 atmospheres if exposed to the hottest rays of the sun (55° C.); and as the heat-conductivity of the porous material is very low, the actual pressure is not likely to reach even this figure.

On charging the cylinders, complete saturation of the acetone does not occur immediately; thus, in a cylinder freshly charged with gas, the pressure rose to 12 atmospheres, but gradually sank in six hours to 7.2 atmospheres. Similarly, time is required for the acetone to give up the whole of the gas during discharge. Tests were made with a cylinder which in each experiment was charged with the same quantity of gas: 96.5 per cent. of the theoretically available volume of gas was utilisable when the discharge occupied 17 hours, and only 65 per cent. when the discharge took place in 1 hour, 22 minutes—the test consisting in supplying the gas to various numbers of burners at their normal rate of consumption, and noting the quantity of gas which had been consumed when the pressure failed.

Kuchel has compared the relative merits, for the illumination of trains, of dissolved acetylene, oil-gas, oil-gas enriched with 25 per cent. by volume of acetylene, and electricity from accumulators, and from his figures the following table has been constructed, the data referring to the output, weight, and measurements of the apparatus required per flame of 14 English candle-power:

Illuminant.	Hours of Light.	Weight in lb.	Space occupied in cu. ft.
German oil-gas, 4.77 c.p. per cu. ft.	96.15	12.0	0.47
British oil-gas, 8 c.p. per cu. ft. . .	161.7	7.1	0.28
Electricity from accumulators	144.0	6.1	0.06
Acetylene oil-gas, 11.8 c.p. per cu. ft.	238.1	4.8	0.19
Dissolved acetylene, 35.5 c.p. per cu. ft.	357.14	0.53	0.005

Kuchel calculates the cost of dissolved acetylene to be 1.552 pf. per hour per flame of 14 English candles, the figures for the other illuminants, on the same basis, being: oil-gas, 2.548 pf.; acetylene oil-gas, 1.798 pf.; accumulators, 8.976 pf.—H. B.

Oxide [Gas-Purifying Material]: Analysis of Spent — H. L. Greville. XXIII., page 1127.

Gases; Washing — and Apparatus therefor. G. M. Capell, Stony Stratford. Eng. Pat. 24,903, Nov. 16, 1904.

THE gas to be washed is drawn or forced through a horizontal chamber which is of smaller cross-section at the inlet than at the outlet end. The chamber is partially filled with water, which may be circulated by means of pipes, connecting the lower portion of the washer with an adjacent water vessel. A series of vertical or inclined shutters depend from the top of the washing chamber and dip to a successively decreasing distance into the water. The gas is thus forced to bubble through a series of water seals and may afterwards be dried by being caused to pass through perforated plates covered with coarse asbestos cloth or similar material, and placed at the outlet end of the washer.—W. H. C.

Electrodes for Electric Arc Lamps; [Flaming Arc] — The British Thomson-Houston Co., Ltd., London. From the General Electric Co. of Schenectady, Schenectady, U.S.A. Eng. Pat. 13,381, June 29, 1905.

Boric oxide, 2 parts, and aluminium, 1 part, are heated slowly together in a Hessian crucible or the like; the mixture is next heated in a refractory crucible, not attacked by boron (e.g. one made of magnesia), to about 2300° C.; and the mass is then allowed to cool slowly, to allow the elementary boron produced to crystallise. After removal of the unaltered boric anhydride and aluminium, and the alumina which has been formed during the heating, the boron is powdered, mixed with carbon, and heated in a carbon crucible in an electric furnace. The product, which appears to consist of boron carbide, B₄C, is powdered, and mixed in the proportion of 2 to 6 parts, with from 6 to 2 parts of titanium carbide and 2 parts of carbon; the mixture is formed into electrodes with the aid of tar or other suitable binder, and the baked electrodes are plated with copper, to prevent oxidation when in use.—H. B.

UNITED STATES PATENT.

Plaster or Mortar [from Spent Gas Lime]; Process of Making — J. B. N. Berry. U.S. Pat. 800,606, Sept. 26, 1905. IX., page 1110.

SEE Eng. Pat. 17,906 of 1904; this J., 1905, 836.—T.F.B.

Fuel; Improving the Combustion of Carbonaceous — J. Harris. Fr. Pat. 554,598, May 24, 1905. Under Int. Conv., Sept. 23, 1904.

OZONE or ozonised air is admitted into the firebox or furnace, to improve the combustion of the fuel.—C. S.

Alcohol; Preparing a New Product for Industrial Purposes, by the simultaneous Concentration and Carburization of — F. Sallé. Fr. Pat. 353,030, June 7, 1905.

COMMERCIAL alcohol is mixed with acetone or other solvent of acetylene and then treated with sufficient calcium carbide to absorb the contained water. The liquid is then separated from the resulting calcium hydroxide by distillation, and the distillate is saturated with the acetylene liberated in the first operation.—C. S.

Stores; Slow-Combustion —, with Channels for the Escape of the Gaseous Products of Combustion. H. Freise. Fr. Pat. 354,131, May 9, 1905. Under Int. Conv., May 21, 1904.

THE vertical gas channels formed on the interior surface of the walls of slow-combustion stoves are connected together at intervals by a series of horizontal channels. The latter are further connected by grooves or channels formed in the brick lining of the stove. The object of the invention is to facilitate the escape of the gases when the vertical channels are partially or completely blocked by small particles of the fuel.—W. H. C.

Gases from Lime, Brick, Cement, Pottery and Porcelain Kilns; Utilisation of Waste — E. Genz. Fr. Pat. 354,796, April 29, 1905. IX., page 1110.

Producer; Suction — Soc. L. Boutillier et Cie. Fr. Pat. 354,479, May 20, 1905.

At the lower part of the producer, and situated above the fire-grate, is provided a recessed, annular reservoir of cast-iron, heated directly by the incandescent fuel, but not attacked by it. The reservoir is kept full of water, and generates steam in quantities proportional to the requirements of the motor which is fed with the gas produced. The steam, issuing from an annular space round the hottest zone of the producer, passes up in contact with the refractory walls of the latter, preventing overheating and the adhesion of clinker. The air supply

enters in a dry state beneath the fire-grate. The producer, and the connected washer, are built up of readily detachable parts, having joints similar to those of gas- or water-mains.—H. B.

Generator for Gas mixed with Steam. E. Schmidt. Fr. Pat. 354,724, May 27, 1905.

A COMBUSTIBLE liquid, such as petroleum, is introduced under pressure, through an atomising jet, into the lower part of a closed boiler-like chamber, where it burns along with a supply of compressed air. Water is injected, through an atomising jet or jets, into the hot products of combustion, soot being thus eliminated from the mixed gas, which is led off at high pressure from the dome of the boiler, to be used directly for motive purposes. A curved plate, extending over the hydrocarbon jet, prevents the water from mingling with the hydrocarbon before the latter is fully inflamed. By means of a thermo-regulator, the temperature of the generator is regulated automatically by the increase or decrease of the water supply. In a second form of the apparatus, the combustion of the hydrocarbon and air takes place in a chamber enclosed within the boiler-like chamber, steam being generated by directing the water spray on to the top of the combustion chamber; and the steam produced mingles with the hot gases issuing from the combustion chamber.—H. B.

Gas under Pressure for Motive Purposes; Process of Preparation of a —. O. Assmann. Fr. Pat. 354,837, May 31, 1905. Under Int. Conv., June 1, 1904.

A GASEOUS mixture at high pressure, suitable for driving a motor, is produced by the sudden combustion of a combustible within a chamber (which may be the cylinder of the motor itself), the heat necessary for causing the ignition being produced either by (1) heating the air and combustible, separately, to the ignition point; or (2) heating the combustible to a temperature short of the ignition point, and the air to a point sufficiently above it to bring about the ignition of the mixture; or (3) heating the air, or air and combustible, beforehand, and then compressing the mixture sufficiently to raise it to the igniting point.—H. B.

Gas Washers. T. Redman. Fr. Pat. 354,570, May 22, 1905. Under Int. Conv., June 4, 1904.

Volatile Compounds, Separation of — by Distillation, and Apparatus therefor. A. G. Green, Leeds. Eng. Pat. 24,363, Nov. 10, 1904.

THE ordinary fractionating column and constant temperature still-head are replaced by the following apparatus. A simple, unobstructed column, coated on its outside with a non-conducting material, is mounted on a still, and connected at the top to a condenser. The liquid to be fractionated is forced by pressure through a heater into a spraying nozzle, which is placed near the upper end of the column, and which may deliver the spray either downwards or upwards as desired. In the latter case, a deflecting plate is placed above the nozzle. The heated spray falls down the column and meets the hot vapours ascending from the still. The less volatile bodies are condensed and returned to the still, whilst the more volatile portions pass on to the condenser. It is

stated that great economy of heat, greater efficiency, and a much more simple method of construction and consequent lower cost are thus obtained. W. H. C.

Dust; Improved Compound which forms an Emulsion with Water to be applied to the Surfaces of Roads or other Places for the Purpose of Preventing the Formation of —. E. Hardcastle and Kay Bros., Ltd. Eng. Pat. 14,239, July 11, 1905. IX., page 1110.

FRENCH PATENTS.

Petroleum Oils Especially Redistilled Oils; Refining —. H. P. J. B. Gollart. Fr. Pat. 350,091, Aug. 1, 1904.

THE oil may be decolorised and deodorised by agitation for 10–15 minutes with about 2½ per cent. of a solution of ferric chloride and about 2 per cent. of hydrochloric acid, after which it is left to settle, separated from the sediment and filtered. Any black particles of iron salts still remaining, can be eliminated by agitation with ammonia or an alkali. Any other soluble ferric salt may be used.—C. S.

Asphaltum and Sulphur or Mixtures of Asphaltum with Pitch, Tar, Resin, Petroleum, Fats, Oils and Analogous Substances; Process for Rendering — Miscible with Water. K. Mann. Fr. Pat. 354,648, May 25, 1905. Under Int. Conv., June 2, 1904.

THE substances, in a state of solution, fine division or suspension, are intimately mixed with soap and some colloidal substance like starch paste, gum, pectins, mucilages, or colloidal oxides or silicates. The soap may be replaced by aqueous solutions or emulsions of fats, resins, lac, oils, waxes, balsams, paraffins, saponin, &c., &c.—C. S.

Petroleum Associated with Ammonia; Emulsifying by Saponification —. E. Charbonneaux. Fr. Pat. 354,884, June 5, 1905.

HALF a gram. of saponin is dissolved in 5 grms. of commercial ammonia and 15 grms. of water, and to this solution 100 grms. of petroleum are stirred in 10 grms. at a time. The oil should have been treated with 5 grms. of amyl acetate, to remove smell and facilitate saponification. The thick, creamy emulsion may be scented with a saponifiable essential oil.—C. S.

Turpentine Substitute; Preparation of a —. A. Pollet. Fr. Pat. 354,425, May 20, 1905. XI11B., page 1118.

Fats, Oils, Resins and Hydrocarbons; Purification of —. C. Fresenius. Fr. Pat. 354,810, May 17, 1905. XII., page 1117.

VI.—COLOURING MATTERS AND DYESTUFFS.

Hydroxyazo Compounds; Reduction of — to Aminophenols by means of Phenylhydrazine. G. Oddo and E. Puxeddu. Ber., 1905, 38, 2752–2755.

THE reaction takes place according to the equation:—

where R represents an aromatic radical. Either an *o*- or a *p*-hydroxyazo compound may be used. One mol. of the hydroxyazo compound is heated with 2 mols. or rather more, of phenylhydrazine. The hydroxyazo-compound dissolves in the base as the temperature is raised. At about 110° C. an energetic reaction occurs with sudden evolution of gas and steam, and rapid rise of temperature. The flame is at once removed, but the reaction continues for about five minutes, the temperature finally rising to 180°–200° C. The temperature then falls, and the gas-evolution becomes less, ceasing altogether on cooling. The aminophenol then often crystallises out, or can be isolated by crystallisation from benzene, followed by recrystallisation from benzene, ligroin or water. In other cases it is better to treat the

product of the reaction with a dilute alkali hydroxide solution, extract the undissolved bases with ether, and precipitate the aminophenol by means of carbon dioxide. The yields are often quite, or almost theoretical. The preparation of 5-amino-eugenol, *o*-amino-*p*-cresol, *p*-amino-carvaerol ($\text{CH}_3\text{:OH:C}_6\text{H}_7\text{:NH}_2=1:2:4:5$) and *p*-aminophenol by this method are described in detail.

—E. F.

Azoxonium Compounds. F. Kehrman.

Ber., 1905, 38, 2952—2962.

THE authors have studied the condensation of phenanthraquinone with *o*-aminophenol in benzene solution, and show that the product obtained is not phenanthrophenazoxine, as they previously thought (see Ber., 1901, 34, 1626; this J., 1901, 799), but a colourless pseudo-base of phenanthrophenazoxonium.

This colourless pseudobase (I.) is converted into the violet coloured salts of phenanthrophenazoxonium (II.) by concentrated sulphuric and other mineral acids. These salts are decomposed by water, first, probably, into the hypothetical violet-coloured true phenanthrophenazoxonium hydroxide (VI.); thence by intramolecular change into a very unstable isomeric yellow pseudo base (V.); which, in the presence of much water, rapidly goes over again into the stable colourless modification (I.).

Thus azoxonium salts may be derived from not only one but two or more different but isomeric pseudo bases. The substances with no quinonoid carbon-nitrogen double bonds are colourless; those with one or more are coloured. The intramolecular changes that take place are due to the disappearance and re-appearance of the double bond. The colourless pseudobase (I.) crystallises in snow-white needles, m. pt. 206° C., and may be dried at 110° C. without decomposition; the yellow modification could not be obtained in a pure state, but its constitution is said to be clearly shown by the behaviour of certain higher homologues, stable in both the white and yellow modifications. By reduction of the colourless pseudo-phenanthrophenazoxonium (I.) with phenylhydrazine, dihydro-oxy-phenanthrophenazoxine (IV.) is obtained. This crystallises when pure in white, glistening needles, and is practically stable in dry air. On heating to 100° C. it is converted into the original pseudo base (I.). When a few drops of dilute hydrochloric acid are added to the alcoholic solution, a molecule of water is split off, and it immediately goes over into pseudo-phenanthrophenazoxine (III.). The latter substance crystallises in yellowish-green fluorescent needles, which are fairly stable in dry air, but are rapidly oxidised to the original pseudo base (I.) when heated to 80° C. It may be also prepared by reducing the latter base with stannous chloride.—H. L.

Terephthalaldehyde Green; Thiele's Xylene-Oxidation and —. P. Claussner. Ber., 1905, 38, 2860—2862.

OCTOMETHYL-TETRAMINOTETRAPHENYL-*p*-XYLENE, the leucobase of Terephthalaldehyde Green, was prepared by condensing terephthalaldehyde tetra-acetate with dimethylaniline by means of zinc chloride; and was converted into the dyestuff, in the usual way, by oxidation with lead peroxide and acetic acid. The dyestuff is very similar to Malachite Green both in shade and, so far as determined, in dyeing properties. Terephthalaldehyde-tetra-acetate was prepared from *p*-xylene by Thiele's method (Annalen., 311, 358), and can be converted into the leucobase without previous hydrolysis into the alde-

hyde. The author found that a mixture of *p*-toluylaldehyde-diacetate $\text{CH}_3\text{C}_6\text{H}_4\text{CH}(\text{OC}_2\text{H}_5\text{O})_2$ m. pt. 69° C., with the tetra-acetate is produced by carrying out the preparation at 5°—10° C., the temperature recommended by Thiele. At —2° to —10° C., the diacetate is almost exclusively obtained, whilst at 10°—18° C., the tetra-acetate is practically the sole reaction product. The separation of the mixtures produced at intermediate temperatures is readily effected by means of alcohol, in which the tetra-acetate is insoluble.—H. L.

Hydroxyquinol; Condensation of — with Aldehydes. E. Heintschel, Ber., 1905, 38, 2878—2883.

LIEBERMANN and Lindenbaum obtained mordant dyestuffs of the fluorone group by combining 2 mols. of hydroxyquinol with 1 mol. of an aldehyde (see Ber., 1904, 1175, 2728; this J., 1904, 485). The author has submitted *m*-nitro- and *m*-bromo-benzaldehyde, and 5-nitro-, 5-bromo-, and 3,5-dibromosalicylic aldehyde to the same reaction, and obtained analogous results. Using terephthalaldehyde, it was found that each of the two aldehyde groups reacted with 2 mols. of hydroxyquinol, with the formation of *p*-phenylene-bis-2,3,7-trihydroxyfluoronone. This dyestuff, in consequence of its greater molecular weight, is distinguished by its very great insolubility, and by the different composition of its sulphate. The shades produced in dyeing are, however, similar to those obtained with the other fluorones.—H. L.

Pyrrhol Blue; The Group of —. C. Liebermann and G. Häse. Ber., 1905, 38, 2847—2853.

THE authors describe as "Pyrrhol Blues" the dyestuffs obtained by combining isatin (1 mol.) with pyrrhol (1 mol.) (see V. Meyer, Ber., 1883, 16, 2974; Camician and Silber, Ber., 1884, 17, 142; this J., 1884, 236), 1 mol. of water being eliminated. Two different products are obtained, both of which are said to resemble indigo.

Pyrrhol Blue A (13 grms.) is prepared by adding at 5° C., 5 grms. of pyrrhol to a dilute solution of 10 grms. of isatin and 50 grms. of sulphuric acid. The dry powder is of a pure indigo blue colour, and contains a small amount of Pyrrhol Blue B. Pyrrhol Blue A is only slowly soluble in concentrated sulphuric acid with a dull violet colour, which turns to blue-black after standing for some time.

Pyrrhol Blue B may be obtained in considerable quantity together with Pyrrhol Blue A, by carrying out the reaction under certain specified conditions. It has a pronounced metallic lustre, and is much less soluble than Pyrrhol Blue A. It dissolves very readily in cold sulphuric acid with a fine violet coloration, soon changing to bright cornflower blue, owing to the formation of a disulphonie acid, which may be easily precipitated and purified. Pyrrhol Blue B contains one atom of oxygen less than Pyrrhol Blue A. Pyrrhol Blue A itself could not be acetylated, but by boiling it with acetic anhydride in pyridine solution, a small amount of a substance was obtained, which was shown to be the acetyl derivative of Pyrrhol Blue B. This is obtained in microscopic needles, possessing a golden lustre. It dissolves in sulphuric acid, producing a splendid Magenta coloration, which soon changes to cornflower blue owing to the formation of a disulphonie acid. This acid is very soluble in water, and the solution dyes silk blue. It may be obtained in lumps possessing a very bright coppery lustre, by evaporation of the aqueous solution. The authors consider the above blue substances of great interest, owing to their resemblance to indigo, and will discuss their constitution and describe other members of the same group later on.—H. L.

Kämpferol (3,4,3'-Trihydroxyflavonol); An Isomeride of —. S. v. Kostanecki and B. Schreiber. Ber., 1905, 38, 2748—2751.

GALLACETOPHENONE dimethylether is combined with anisaldehyde to form 2'-hydroxy-3',4',4'-trimethoxy-chalkone. $(\text{CH}_3\text{O})_2(\text{OH})\text{C}_6\text{H}_2\text{CO}\cdot\text{CH}(\text{CH}_3\text{C}_6\text{H}_4\text{OCH}_3)$. This is converted in the usual manner, though with some difficulty, into 3,4,4'-trimethoxyflavone,

By the action of amyl nitrite and hydrochloric acid this is changed into its α -isonitroso-derivative, which forms 3,4,4'-trimethoxyflavonol,

on boiling with a mixture of acetic and dilute sulphuric acids. By boiling with hydriodic acid this trimethoxyflavonol is converted into 3,4,4'-trihydroxyflavonol,

which crystallises in light yellow needles. It dyes mordanted fabrics strongly, giving orange-yellow shades on alumina mordant.—F. F.

Dyestuffs; Production of Yellow Sulphide—, Act.-Ges. f. Anilinfabr. Fr. Pat. 351,307, May 15, 1905.

A MIXTURE of acetyl-*o*-, *p*-, or *m*-toluidine with benzidine is heated with sulphur to 220–241° C. for some hours. The melt is powdered, dissolved by boiling with aqueous sodium sulphide and filtered. The dyestuff is then precipitated from this solution in the usual way. The process and the dyestuffs are similar, whichever isomeride is employed. The products are easily soluble in sodium sulphide, and dye unmordanted cotton in very bright yellow shades, stated to be very fast to milling, acid and alkalis. None of the isomeric acetyl toluidines yields a dyestuff when fused with sulphur without the addition of benzidine.—H. L.

Anthraquinone Derivatives containing Nitrogen; Production of—, Soc. Farbent. vorm. F. Bayer und Co. Fr. Pat. 351,717, May 27, 1905.

AMINO-, alkylamino- and arylaminoanthraquinones are produced by heating alkyl- or aryl-ethers or aryl-thio ethers of the anthraquinone series with ammonia, with primary or secondary aliphatic amines, or with primary aromatic amines respectively.

Example I.—A mixture of 10 parts of 1-nitro-4-methoxy-anthraquinone (prepared by nitrating the methyl ether of erythrohydroxyanthraquinone) with 50–100 parts of *p*-toluidine is heated to 160–180° C. for three to four hours, until the mass has assumed a deep bluish-green colour. On cooling and diluting the melt with alcohol, 1,4-di-*p*-tolyl-diaminoanthraquinone crystallises out. The same product may be prepared by starting from 1-methoxy-4-phenoxyanthraquinone, from quinzarin dimethyl ether or from 1-methoxy-4-bromoanthraquinone.

Example II.—100 parts of a 10 per cent. solution of methylamine in pyridine and five parts of the phenyl ether of erythrohydroxyanthraquinone are heated in an autoclave for five hours, at a temperature of 150° C. By adding water to the cold melt α -methylaminoanthraquinone is obtained in crystals. The same substance is obtained by starting from methoxyanthraquinone. If the methylamine be replaced by aniline, phenylaminoanthraquinone is obtained, if by β -naphthylamine, then β -naphthylaminoanthraquinone is formed.

Aryl ethers of anthraquinone are prepared by treating anthraquinone derivatives containing negative groups

with phenol and caustic alkalis. Thioethers can be obtained by the action of mercaptans, *e.g.*, thiophenol, on nitroanthraquinones in the presence of caustic alkalis.—H. L.

Silk; Production of Textile — Soc. Anon. pour l'Etude Ind. de la Soie Serret. Fr. Pat. 354,336, May 16, 1905.

WASTE silk or other material containing silk may be converted into "silk threads of as good quality if not better than that of the best natural silks," by dissolving it in any solvent which does not instantaneously decompose silk, and forming it into threads before the silk has been altered by the solvent. For instance, silk is dissolved in hydrochloric acid, and as soon as solution is complete, the mass is neutralised or very strongly diluted. A gelatinous and sticky mass is thus obtained which may be formed into threads. The same result is obtained by cooling the solution to below 0° C., and forming the solution into filaments directly without neutralising. In this case neutralisation is effected as the threads make their exit from the apertures.—H. L.

Silk by the Chardonnet Process; Recovery of the Cotton Wool and Muslin used for Filtering Collodion in the Manufacture of Artificial — Soc. Anon. pour la Fabrication de la Soie de Chardonnet. Fr. Pat. 354,398, May 17, 1905.

THE filters consist of cotton wool wrapped in muslin, and rapidly become impregnated with pyroxylin, owing to the evaporation of the solvent, and have to be renewed. Filtration is thus a burdensome operation, as the cotton wool and muslin are expensive, and the old caked filters have hitherto been burnt as a useless and possibly dangerous by-product. The process now described is for the recovery of the cotton wool and muslin by treatment of these "filter cakes." Any solvent for pyroxylin, or

denitrating agent may be employed, but the best results are obtained by treatment at 70°–90° C. with a 1–2 per cent. solution of sodium or potassium carbonate, or a 2–5 per cent. solution of an alkali sulphide. In this way the pyroxylin is completely dissolved, and may be removed with the greatest ease by a single washing with water. The cotton wool is left unaltered, and after being dried, and if necessary, recombed, may be directly used again for filtering; or it may be nitrated. The dark brown solution of the pyroxylin is evaporated; and the residue is calcined and converted into cellulose. The net cost of the process is stated to be insignificant, the plant rudimentary, and the labour practically nil. The operation may be carried out in any ordinary bleaching kier, and a particular form of the latter is described and also claimed.—H. L.

Silk; Method of Making Non-inflammable Artificial — G. Gorrand. Fr. Pat. 354,424, May 19, 1905.

BY the use of a mixture of amyl alcohol, ethyl acetate and acetone for dissolving the nitrocellulose, it is stated that a non-inflammable artificial silk of great brilliancy is obtained. A few drops of acetic acid are added to the nitrocellulose solution, in order to accelerate the denitrication, which is carried out with ammonium sulphhydrate.—T. F. B.

Fibres and Fabrics of all Descriptions; Oiling of — Deutsche Kuehloel Werke Bauer and Co. Fr. Pat. 353,947, April 22, 1905.

A PRODUCT for oiling fabrics such as wool, cotton, jute and hemp, in place of the oils and emulsions of oils usually employed, is described. 100 kilos. of castor oil are heated to nearly 99° C. with 50 kilos. of caustic potash of 50° B., to which 50 kilos. of water have previously been added. Forty litres of cooler water are then added slowly, care being taken to keep the temperature of the mixture constant. As soon as the liquor begins to rise, 40 litres of cooler water are again added, with the same precaution to keep the temperature from falling below 99° C. At the same time care must be taken to prevent the liquor boiling, as this would produce too great saponification. By the prolonged action of heat below the boiling point, the oil, it is stated, absorbs water and caustic potash without being changed, and the whole finally forms a perfectly limpid, nearly black liquid. This is diluted with five times its weight of hot or cold water, and is then ready for use without any further preparation. Other vegetable oils may be employed besides castor oil, and the quantity of unsaponified oil present may be increased by stirring the prepared liquid with a fresh quantity of castor or other vegetable oil. The product is slightly alkaline, but wool fibre is not injured, as the oiling may be done in the cold. The solution is clear and limpid, and will not separate out on standing like an emulsion.

It is claimed for this product that:—(1) In spinning it gives a 10 per cent. better utilisation of the raw material owing to the greater evenness and regularity with which the fibres are oiled; (2) In weaving less oiling is required.

The product can be completely removed by water, preferably by cold water, and scouring of the goods subsequently with soap, soda, or fuller's earth can thus be dispensed with.—H. L.

Silk or other Similar Products on Bobbins or Rollers; Double Continuous Machine for Washing Artificial — J. Foltzer. Fr. Pat. 353,973, May 4, 1905.

ARTIFICIAL silk threads, after having been wound on to bobbins, have to be thoroughly washed to completely remove the precipitating liquor or other substances with which they are impregnated. This washing has hitherto been carried out by hand on a wooden framework. In the present machine two horizontal shafts (see Figs. 1 and 2 which represent side and front view respectively) are fixed on two supports 1 and 2. The lower shaft is controlled by means of pinions 3 and 4, and an endless screw 5. Each shaft carries one or more pulleys 6 and 7, over which an endless chain 8 travels. On this chain suitable supports 9 are fixed to carry the bobbins 10. In operation the bobbins are first placed in the lowest receptacle, and are

submitted to a continuous stream of water from sprinklers 11 and 12 as they slowly mount upwards. The washed bobbins finally descend on the far side of the machine and

are then removed and dried. They may be turned during the process by means of ratchet wheels 13 and 14 and catches 11.—H. L.

Silk; Process of Treating [Weighting] — The Jochen Silk Weighting Co. Fr. Pat. 344,927, June 3, 1905.

SEE U.S. Pat. 792,218 of 1905; this J., 1905, 799. —T. F. B.

Wool; Detergent for Degreasing — S. Wohle. Fr. Pat. 354,702, May 27, 1905. Under Int. Conv., June 3, 1904.

THE wool in its original bales is placed in a cylinder provided with a piston; the cylinder is closed, and a suitable volatile solvent is run on to the top of the bale, in such a manner that all the wool is saturated. By compressing and releasing the bale several times, by means of the piston, all the grease is said to be extracted; the solvent is now run off, and the bale is compressed once more to remove as much of the solvent as possible, and then dried. The apparatus consists of a compression chamber provided with a piston, a filter for the used solvent, a still, a condenser, and drying chambers, together with the necessary pumps.—T. F. B.

Wool; Detergent for Degreasing — S. Wohle. Fr. Pat. 354,702, May 27, 1905. Under Int. Conv., June 3, 1904.

SEE Eng. Pat. 12,632 of 1904; this J., 1905, 671. —T. F. B.

Fabrics; Printing on Vegetable or Animal — E. Joly. Fr. Pat. 350,041, July 6, 1904.

THE process is for producing iridescent or nacreous effects on vegetable, animal or mixed fibres. In principle it consists in printing a ground by means of one roller and then passing the goods over two other rollers engraved with shaded-off designs, the first of which prints horizontal, the latter vertical stripes. The required effects are produced by the superimposition, and by the gradation and shading down of the colours and by the crossing of the multicoloured designs.—H. L.

VI.—COLOURING WOOD, PAPER, LEATHER, &c.

FRENCH PATENTS.

Printing and Embossing [Paper, &c.]; Machine for — C. H. Jeanson. Fr. Pat. 354,137, May 9, 1905.

A NUMBER of ink-troughs 1, 2, 3, (see fig.) are placed in contact with the inking rollers 4, 4', 5, 5', 6, 6', and

the latter ink the same number of cylindrical clichés, each marking one cliché in the corresponding colour. The clichés are fixed on cylinders 7, 8 and 9, and only partially envelope these cylinders. Cylinders 7, 8 and 9 in their turn carry forward all the colours which they receive to an intermediate cylinder 10, made of smooth and elastic material. By suitable adjustment of the movements of cylinders 7, 8, 9 and 10, the colours are deposited on cylinder 10, at the place required for the design. Cylinder 10 brings all the colour it receives on to a general cliché placed round cylinder 11. The paper or other material 13 for printing and embossing, is passed between cylinder 11 and its counterpart cylinder 12. Immediately after leaving cylinders 11 and 12 the material passes between the embossing calendars 14 and 15. The latter rotate at the same tangential velocity as cylinders 11 and 12, in order to keep the material in shape; and the distance between the printing and embossing cylinders should be cut down to the strict minimum.—H. L.

VII.—ACIDS, ALKALIS, AND SALTS, AND NON-METALLIC ELEMENTS.

Perechromates. K. A. Hofmann and H. Hiendlmaier. Ber. 1905, 38, 3059—3066.

Nitrogen; Action of — on Water Vapour at High Temperatures. O. F. Tower. J. Amer. Chem. Soc., 1905, 27, 1209—1216.

THE combination of nitrogen and oxygen and the dissociation of water vapour at high temperatures have recently been studied by Nernst and von Wartenberg (Nachr. Kgl. Ges. Wiss., Göttingen, 1904, [4] and 1905, [1]). The results obtained show that at high temperatures, nitrogen will act on water vapour, to a certain extent according to the following equation; $\text{N}_2 + 2\text{H}_2\text{O} = 2\text{NO} + 2\text{H}_2$. The author studied the reaction quantitatively by passing nitrogen saturated with water vapour through an iridium tube heated electrically to about 2000° C. The yield varied from 0.5 to nearly 3 c.c. nitric oxide per litre of moist nitrogen. The issuing gas was passed first through a tube (i) containing sulphuric acid, then mixed with oxygen, which converted any nitric oxide into nitrogen peroxide, and finally passed through a second tube (ii) containing sulphuric acid to absorb the nitrogen peroxide. The results obtained are shown in the following table:—

Expt. No.	Temperature.	Duration of experiment.	Nitrogen passed through.	Total volume of gas.		Rate of passage of gas.	Nitric oxide found.			
				$\text{N}_2 + \text{H}_2\text{O}$ passed through.			i.	ii.	i. + ii.	Per hour.

sulphuric acid, decomposes explosively. Heated with sodium hydroxide solution, it gives off two "equivalents" [half atoms] of oxygen, and leaves sodium chromate. Heated with dilute acid it evolves three equivalents of oxygen, leaving a violet-red solution apparently containing chromium peroxide. A modification of this substance is obtained if ammonium bichromate be dissolved in 20 per cent. aqueous ammonia, and the solution, before adding the hydrogen peroxide, be saturated with ammonia gas. This β -form differs in many physical characters from the α -form, but their general chemical behaviour is similar. The addition of hydrogen peroxide to a cooled saturated aqueous solution of ammonium bichromate, to which ammonium nitrate has previously been added, gives the ammonium perchromate $\text{NH}_4\text{CrO}_5 \cdot \text{H}_2\text{O}_2$ already described by Wiede (this J., 1898, 78 and 348); the substance is much more readily prepared in this way than by Wiede's method.—J. T. D.

Phosphorus Pentasulphide. A. Stock and K. Thiel. Ber. 1905, 38, 2719—2730.

BESIDES ordinary phosphorus pentasulphide (advantageously prepared by heating together phosphorus and sulphur dissolved in carbon bisulphide, to which a trace of iodine has been added, in sealed tubes at 120° C., and repeatedly recrystallising from carbon bisulphide), the authors find another modification exists, prepared by suddenly cooling the vapour of the ordinary sulphide, and fractionally treating the product with carbon bisulphide. The following comparative table shows the points of difference yet established between the two:—

The presence of nitric oxide (or rather, nitrogen peroxide in tube (i.) before mixing the reaction products with oxygen, is due to the diffusion of some hydrogen through the hot iridium tube, whereby excess of oxygen was left, which oxidised some of the nitric oxide to nitrogen peroxide.—A. S.

Lime or the like; Apparatus for Slaking — to Produce "Efflorescence" therein. K. Tsuji, Takaoka, Japan. Eng. Pat. 2346, Feb. 6, 1905.

THE lime to be slaked is delivered into a wide pipe entering a revolving cylinder, having internal radial shelves,

which pick up and drop the material, and plates between the shelves, with their faces arranged at an angle to the axis of rotation. The plates act as an interrupted screw, and carry the charge forward to the discharge end, meeting a current of steam carrying water spray mixed with air. The steam, charged with fine dust in suspension, issues from an exit pipe in the entrance end of the drum and passes to a screening apparatus containing a number of cloth-covered filter frames, through which it is drawn by the action of one or more fans.—E. S.

UNITED STATES PATENT.

Lime; Process of Treating [Hydrating] — C. Ellis, Boston, Mass. U.S. Pat. 800,635, Oct. 3, 1905.

A stream of quicklime is caused to meet, at a certain point, sufficient water to form therewith the dry hydrate. The mixture of lime and water is then conducted away from the point of mingling, whilst being subjected to mechanical agitation without further addition of water, until the lime is completely converted into the dry hydrate.—E. S.

FRENCH PATENTS.

Sulphuric Acid; Chamber for the Manufacture of — C. W. Grosse-Legge. Fr. Pat. 354,831, May 31, 1905. Under Int. Conv., June 1, 1904.

Is the chamber process for the manufacture of sulphuric acid, according to this invention, the chambers are constructed with a conical base, merging above into an upright cylinder. The gases are introduced with steam or atomised water at the side, near to the bottom, and, striking the opposite side, are deflected thence, and so repeatedly on their ascent, from side to side, so that they take a helical course, and constantly impinge against the chamber walls, which are kept moist by the dilute acid formed. The gases leave the chamber near the top, thence passing to near the bottom of the next chamber. From a perforated trough fixed round the outside of the upper part of the chamber, water trickles down the sides, with cooling effect.—E. S.

Sodium Sulphate and Concentrated Hydrochloric Acid Gas; Muffle Furnace for the Manufacture of — Obriating the Disengagement of Obnoxious Vapours. K. Oehler. Fr. Pat. 354,467, May 4, 1905.

The charge is heated in a closed muffle, from which the acid vapours are conducted away for condensation without access of air, into a receiver in which the gas meets with an excess of moisture. The floor of the muffle is provided, near the working doors, with traps, through which the sodium sulphate is discharged into a channel beneath, from which it is conveyed by an endless chain into a closed receptacle in which cooling is effected. As the discharge takes place, communication is opened to a tuyère leading to a secondary condensing arrangement, and opening into the roof of the muffle, close to the door from which unabsorbed gases are drawn through the action of diminished pressure, thus avoiding escape into the air of acid vapours. The system of pipes, with their connections and means for directing the gases as required, are shown. Reference is made to Fr. Pat. 318,386 of Feb. 4, 1902; this J., 1902, 1454. (Compare also Eng. Pat. 2856 of same date; this J., 1903, 93.)—E. S.

Barium Carbonate; Manufacture of — P. Seurre. Fr. Pat. 354,419, May 18, 1905.

EQUIVALENT quantities of native barium sulphate and calcium chloride, with a few per cents. of wood charcoal, all in powder, are mixed and placed in a crucible, which is heated, with agitation, until the contents are fused. The mass, treated with water, gives barium chloride in solution, and a residue of calcium sulphate. The cleared barium chloride solution is treated with ammonium carbonate solution to obtain a precipitate of barium carbonate, and ammonium chloride in solution, from which ammonium carbonate may be re-formed by treatment with chalk.—E. S.

Carbonates of Potassium, Sodium and Calcium; New Process of Making — A. P. Podanowsky. Fr. Pat. 354,966, June 5, 1905. Under Int. Conv., June 9, 1904.

Silica and Analogous Material; Attachment of Metals to Objects of Fused — J. F. Bottomley, Walsend-on-Tyne, and A. Paget, North Cray, Kent. Eng. Pat. 21,018, Sept. 30, 1905.

METALS may be directly attached to objects of fused silica, either with the object of insulating the metal or of attaching the silica to other pieces of apparatus, by casting the metal around or within the fused silica. In the case of the harder metals, however, which have high coefficients of expansion, it is necessary to protect the silica, which has a very low coefficient of expansion, from the crushing stresses produced by the contraction of the surrounding metal. This is done by leaving hollow spaces between the silica and the metal, which are partly or wholly filled with some suitable material, such as asbestos. Thus, in casting iron around a tube of silica of external diameter 1 in. and walls $\frac{1}{4}$ in. thick, a wrapping about $\frac{1}{4}$ in. thick of thin asbestos cord and powdered asbestos may be used. In casting metals inside a mass of silica, the inner surface of the latter may be roughened, so as to give the metal a hold on the silica as it contracts. Metals with high elongation are to be used wherever possible.—A. G. L.

FRENCH PATENTS.

Glass-Pot. R. A. J. Blondel. Fr. Pat. 354,379, May 17, 1905.

THE pot is characterised by being divided into two compartments by a vertical partition, which near the centre of the pot widens out into a vertical pipe, preferably of elliptical cross-section. The flames enter this pipe at the top and pass out through a horizontal passage formed in the base of the pot. The two compartments communicate by means of a round hole in the lower part of the partition; each compartment is provided with a separate mouth, through one of which the raw materials are introduced, whilst the other serves for withdrawing the molten glass.—A. G. L.

[Glass] Furnace for Continuous Working at High Temperatures. C. J. Hurrell and L. Houze. Fr. Pat. 354,544, May 23, 1905.

BURNERS are placed in the rear portion of a glass tank furnace on each side in such a way that the flames from

the burners on one side beat against the flames from the burners on the other side. The flames then have to pass across the furnace and escape through a number of longitudinal openings in the sides of the furnace, passing through passages on their way to the chimney, which provide means for preheating the air necessary for combustion.—A. G. L.

Silica; Method of Working Fused — J. F. Bottomley and A. Paget. Fr. Pat. 354,842, May 31, 1905. Under Int. Conv., Aug. 25, 1904.

SEE Eng. Pat. 18,434 of 1904; this J., 1905, 846.—T. F. B.

[*Ceramic Product*]. *Use in the Ceramic Industry of Earth found in Alluvial Deposits, either naturally possessing a Special Composition, or else Mixed Artificially*. J. Dessane. Fr. Pat. 354,201, May 9, 1905.

The earth used, is dried, reduced to powder, and moulded, after moistening it with the smallest quantity of water possible, after which it is burnt at about 900° C., a semi-vitrified red product of great hardness and resistance to abrasion being obtained. By burning at 1000° C. instead of 900° C., a black fully vitrified product of but limited application is obtained. By substituting other metallic oxides for the ferric oxide in the raw material, differently coloured objects may be produced.—A. G. L.

Gases from Lime, Brick, Cement, Pottery and Porcelain Kilns; Utilisation of Waste — E. Genz. Fr. Pat. 354,796, April 29, 1905. IX., see below.

Photographs; Process for Obtaining —, in Relief on Ceramic Objects. A. and P. Dalpayrat. Fr. Pat. 354,694, May 27, 1905.

FILMS are made of a mixture of 75 grms. of gelatin, 4 of potassium bichromate, 4 of albumin, 30 of alcohol, and 2 of fish-glue, with a quantity of water depending on the amount of relief it is desired to obtain. These films are covered with a negative and exposed in the ordinary way, after which they are placed in water heated to about 45° C., when the portions unaltered by the light swell up. When the development is sufficient, the film is cooled and a mould of plaster of Paris made from it, from which the porcelain object is next made. This is burnt, covered with enamel, and again burnt.—A. G. L.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

ENGLISH PATENTS.

Stone; Manufacture of Artificial — A. H. H., and G. van der Vijgh, all of Amsterdam, Holland. Eng. Pat. 23,364, Oct. 29, 1904.

THIS invention is an improvement on that described in Eng. Pat. 23,159 of 1898 (this J., 1899, 147). Artificial stone is now made from a mixture of pumice stone, 70; Portland cement, 10; hydraulic lime, 10; and water, 10 per cent.—A. G. L.

Wood; Preservation of — H. H. Lake, London, from Rütgerswerke Act.-Ges., Berlin. Eng. Pat. 22,990, Oct. 25, 1904.

WOOD is impregnated in the usual manner with a hot solution, saturated at 100° C., of zinc β -naphthalenesulphonate, which mostly separates out in the pores of the wood on cooling. An addition of 10 per cent. of sodium chloride may be made for the purpose of rendering the zinc salt still more insoluble in cold water. The magnesium β -naphthalenesulphonate may also be used with advantage instead of the zinc salt. In this case the acid mixture obtained by the action of excess of sulphuric acid on naphthalene may be directly neutralised with magnesium oxide or carbonate; whereas, if the zinc salt is to be made, the acid mixture must first be neutralised with lime, after which the zinc salt is obtained by double decomposition of the calcium sulphonate with zinc chloride.

—A. G. L.

Dust; Improved Compound which forms an Emulsion with Water to be applied to the Surfaces of Roads or other Places for the purpose of Preventing the Formation of — E. Hardeastle and Kay Bros., Ltd., both of Stockport, Cheshire. Eng. Pat. 14,239, July 11, 1905.

A MIXTURE of 50 gall. of coal tar creosote, 1 cwt. of coal tar pitch and 2½ cwt. of rosin is heated until solution is effected. A solution of 28 lb. of caustic soda or potash in 18 gall. of water is poured into the first liquid, and the whole is agitated until completely combined, when it is mixed into an emulsion with water and sprinkled on roads.—A. G. L.

Cement; Method of and Means for Burning — B. E. Eldred, New York. Eng. Pat. 25,837, Nov. 28, 1904.

UNITED STATES PATENTS.

Plaster or Mortar [from Spent Gas Lime]; Process of Making — J. B. N. Berry, Washington, D.C. U.S. Pat. 800,606, Sept. 26, 1905.

SPENT lime from gas-purifiers, in which the sulphur has been converted into calcium sulphate, by exposure to weather, if necessary, is mixed with clay rich in alumina. The mixture is powdered, formed into balls or blocks with water, and calcined at a temperature below that at which the setting qualities of calcium sulphate are destroyed. Slaked lime, clay and sand are added to the calcined product, and the whole is finely powdered.—A.G.L.

Structures; Process of Rendering — Impervious against various Agents. M. Toch. U.S. Pat. 800,956, Oct. 3, 1905. XIII.A., page 1117.

FRENCH PATENTS.

Slag or other Mixture of Silicates to Facilitate Hydration; Preliminary Treatment of Blast-Furnace — B. Bruhn. Fr. Pat. 354,790, April 18, 1905. Under Int. Conv., April 19, 1904.

A SMALL percentage of alkali or alkali salt is added to the blast-furnace slag or other silicate mixture, either before or during the cooling, the presence of the alkali facilitating the subsequent hydration with water.—A. G. L.

Gases from Lime, Brick, Cement, Pottery and Porcelain Kilns; Utilization of Waste — E. Genz. Fr. Pat. 354,796, April 29, 1905.

THE waste gases from kilns are mixed with producer- and water-gas in such proportions that the final mixture of gas contains about 16 per cent. of carbon monoxide, 2 per cent. of heavy hydrocarbons, 2 per cent. of hydrogen, and 11 per cent. of carbon dioxide. This mixed gas may be utilised for heating or power purposes.—A. G. L.

Cement, Lime, &c.; Kiln for Burning — N. Perpignani and E. Candlot. Addition dated May 17, 1905, to Fr. Pat. 335,377, Sept. 18, 1903. (This J., 1904, 188.)

To allow the kiln to be charged continuously, the upper part is left uncovered, and the gas is drawn off through a short central tube which dips into the charge.—C. S.

Cement-Kiln with Continuous Charging and Discharging. N. Perpignani and E. Candlot. Fr. Pat. 354,595, May 24, 1905.

THE materials to be burnt are charged into the annular space between the kiln-walls and a central tube, which serves as a chimney for the burnt gases. This tube extends some way into the kiln; the space around it is always open, so as to allow of continuous charging. Between the upper and lower part of the interior of the kiln is inserted a horizontal grating resting on a cast iron cylinder, below which is placed a vertical cylindrical grating through which the burnt material passes on its way to the exit openings in the base of the kiln. The air needed for combustion passes between the walls of the kiln and the above mentioned internal cylinders and through the horizontal grating, and becomes heated in so doing.

—A. G. L.

X.—METALLURGY.

Ore; Use of High Percentages of Fine — in a Charcoal Blast-Furnace. H. R. Hall. Bull. Amer. Inst. Mining Eng., 1905, 1107—1110.

THE author describes the conditions under which successful results were obtained in the manufacture of pig-iron from magnetic concentrates and "cobbed" ore with charcoal fuel, weighing from 12 to 20 lb. per bushel. The charcoal was made from hemlock, pine, spruce, balsam, maple, beech and birch woods. The concentrates contained 62—65 per cent. of iron, and would all pass an $\frac{1}{8}$ -in. screen, whilst 34 per cent. would pass an 80-mesh sieve. The cobbed ore contained from 32 to 47 per cent. of iron, and from 23—32 per cent. of silica; it would all pass through a 1-in. ring, and about 25 per cent. would pass an $\frac{1}{8}$ -in. screen. During one period of working the smallest day's output was 66 tons, and the largest 113 tons of pig-iron, the total output for one month being 2777 tons, with a fuel consumption of 114 bushels (average weight, 17 lb. per bushel) of charcoal per ton of pig-iron. The ore charge consisted of about 15 per cent. of cobbed ore, and 85 per cent. of concentrates. Later, in a period of five months, an ore charge of concentrates only was employed, the furnace-charge consisting of 1.6 tons of concentrates, 89 bushels of charcoal (average weight, 20 lb. per bushel), and 200 lb. of limestone per ton of pig-iron produced. During this period, the average daily output was 89 tons of pig-iron, and the loss of ore blown out of the furnace in the form of dust amounted to 6 per cent. of the quantity charged. The volume of air used was about 5625 cu. ft. per minute. In the same furnace with coke fuel, 60 tons of pig-iron per day were produced for a month with a fuel-consumption of 2220 lb. of coke, whilst the loss of ore-dust was 25 per cent. when the same volume of air was used as with charcoal. Coke is generally regarded as the ideal fuel for making pig-iron, but the author points out that charcoal is more advantageous, on account of its low content of ash and its freedom from sulphur. Moreover, it is estimated that a charcoal furnace of the same size as a coke-furnace will produce, in the same time, from 25 to 33 per cent. more pig-iron. The following table shows the general relation between hearth-area and daily output of a charcoal furnace:—

Diameter of hearth, in feet...	7	7.5	8	8.5	9
Output of furnace, in tons....	110	133	161	192	225

—A. S.

Blast-Furnace Gases; Application of —, to the Reduction of Iron Ore for the more recent Open-Hearth Steel Processes. O. Simmersbach. Stahl u. Eisen, 1905, 25, 1187—1189.

IN the recent modifications of the open-hearth process in which the molten pig-iron is run direct into the hearth, the addition to the charge of as large a proportion of ore as possible presents itself as desirable, for the cost of iron as ore is much lower than that of iron as metal. But the amount of ore that can be added is limited by the amount of reducing impurities permissible in the metal, and reduction of the ore by the furnace-gases increases the duration of the charge and lessens the daily output of the furnace. The author proposes, therefore, to reduce the ore (beyond that needed for the oxidation of the impurities in the metal) in a separate furnace, and to utilise blast-furnace gases for that purpose; basing his proposal on the facts (1) that the reduction of ferric oxide by carbon monoxide, the materials having been heated up to the temperature needed for it, requires no thermal assistance from without, but gives out a small amount of heat, and (2) that the composition of the gases at the mouth of the blast-furnace is practically the same as at the level at which they actually reduce the ore, 30 ft. below.

The diagram shows the principle on which his furnace is constructed. It is heated by blast-furnace gas, burning at the burner A (section I.) at the bottom of the vertical channels in the brickwork casing, to the necessary tempera-

ture (800° C.), and the reduction of the ore is effected by the same blast-furnace gas introduced without air at D (section II). The furnace below D is cooled by water, so that the spongy iron can be withdrawn by the side opening E and the door F without re-oxidising on its way to the steel-furnace. Clearly the inner portion of the double casing must not be too thick; and producer-gas or similar gas may be substituted for blast-furnace gas.—J. T. D.

Bessemer-Martin Process at Witkowitz; Chemical Processes in the Combined —. C. Canaris. Stahl u. Eisen, 1905, 25, 1125—1127.

THE process in use at Witkowitz, Germany, consists essentially in blowing the pig-iron in an acid-lined Bessemer converter till the greater part of the silicon, manganese and carbon is removed, and then treating the metal in a basic Martin furnace to de-phosphorise it. The author investigated the chemical reactions which take place in the process. Two charges were worked. In the first, 22,280 kilos. of molten pig-iron from the converter were further treated in the Martin furnace with 1100 kilos. of burnt lime, 400 kilos. of Gellivera ore (Swedish magnetite), 500 kilos. of Martin pig-iron, 1000 kilos. of steel cuttings, and 200 kilos. of 77 per cent. ferro-manganese. In the second case the charge for the Martin furnaces was the same as before with the exception that the amount of molten pig-iron from the converter was 21,790 kilos., whilst 210 kilos. of ferro-manganese were added. It was found that in the converter, silicon and manganese were oxidised first, then the oxidation of the carbon began slowly, but became more rapid as the temperature rose, and the amount of manganese decreased. The beginning of the "boiling" period could be recognised distinctly by the sudden fall in the carbon content of the metal (from over 2 to less than 0.7 per cent.). Owing to the high temperature attained during the "boiling" period, the silicon and manganese were also oxidised more rapidly than in the earlier stages. The percentage of phosphorus usually became slightly higher, owing to oxidation of the iron. In the Martin furnace, the phosphorus passed rapidly into the slag. The addition of ferro-manganese had little effect on the percentages of manganese and carbon in the final product, as the manganese was, for the most part, utilised in de-oxidising the metal, whilst the carbon was rapidly oxidised.—A. S.

"Temper-Carbon" and Graphite: the two Forms of Carbon in Iron. F. Wüst and C. Geiger. Stahl u. Eisen, 1905, 25, 1134—1139, and 1196—1202.

THREE views exist as to the nature of "Temper-carbon" (see also this J., 1904, 985): Ledebur regards it as a carbide, James as a modification of graphite, Wüst and Jüptner as pure amorphous carbon. The authors have endeavoured to elucidate the conditions for its formation and its modification or destruction, by heating cast-iron, white and grey, to various temperatures for various periods, and quenching in a variety of ways. Their results are summarised as follows:—1. Temper-carbon is formed in small amounts at comparatively low temperatures (say 900° C., but the minimum temperature depends on the other constituents of the iron), but the length of time to produce a given quantity is greater as the temperature is lower. 2. As soon as a certain temperature, dependent on the composition of the iron, is reached, the greater part or the possible temper-carbon is formed suddenly: and the higher the temperature the greater the amount thus suddenly formed. 3. Continuance of the heating increases but slightly the amount of temper-carbon. 4. The rate of cooling of the iron influences but slightly the amount of temper-carbon, though rapid cooling greatly modifies the structure and the strength. 5. Frequent reheating of a sample in which temper-carbon has been already formed increases the amount, the more so as the temperature is higher. 6. Quenching from any temperature below the melting point, does not diminish the amount of temper-carbon: hence it is in all probability not a carbide. 7. Heating in pure hydrogen or nitrogen does not, contrary to hitherto received opinion, lessen the amount of temper-carbon: it can only be reduced in amount by the action of oxidising substances (water vapour, carbon dioxide, ferric oxide), so that the presence of such substances is necessary for the tempering process. 8. Graphite is removed by these oxidising substances in the same way as temper-carbon.

The experiments on the conversion of temper-carbon and graphite into the gaseous form and their consequent removal showed that the gaseous substances concerned—water vapour, hydrogen, oxygen, carbon dioxide, carbon monoxide—permeated the whole substance of the iron, the central parts of the sample rods being affected equally with the outer portions: and, as might have been expected, the porous graphitic irons showed themselves more readily permeable than those of closer structure.

—J. T. D.

Manganese-Iron Alloys. M. Leyn and G. Tammann. Z. anorg. Chem., 1905, 47, 136—141.

IN the determination of the heating and cooling curves of manganese-iron alloys, special precautions are necessary owing to the strong action of fused manganese on the porcelain crucible containing the metal and on the porcelain sheath of the thermo-element. To protect the

thermo-element the porcelain sheath was enclosed in a cap of nickel or platinum, and the latter covered with a coating of magnesia. The iron used in the experiments contained only 0.07 per cent. of carbon and very small quantities of lithium, manganese, phosphorus, sulphur and copper. The manganese contained small quantities of iron, copper and silica. The melting point of manganese was found to be 1247° C. In the experiments, the beginning of the crystallisation and the end of the melting period could be readily detected, but the lower breaks in the curves (corresponding to the end of the crystallisation and the beginning of the melting period respectively) were very indistinct, and were only estimated approximately from the rates of cooling and heating, and then corrections made. The results obtained are given in a table and are also shown in the accompanying curve-diagram. The form of the curve shows that no compound of manganese and iron separates from the melts, the two metals forming an uninterrupted series of mixed crystals. The results of the micrographic examination of the alloys did not appear to conform to this view, since in a number of cases, two different structural elements could be recognised distinctly, but this was found to be due to the fact that, owing to relatively rapid cooling, complete equilibrium between the melt and the separated crystals did not occur, so that the solid alloy consisted of primary crystals richer in iron, surrounded by secondary crystals richer in manganese. With slower cooling, the alloys had a practically homogeneous structure.

It was found that the addition of manganese to iron causes a strong diminution in the magnetic permeability of the latter. The temperatures at which the magnetic permeability of the alloys undergoes sudden change are shown in the following table:—

Percentage of Iron.	Magnetic permeability.	
	Disappears.	Re-appears.
	°C.	°C.
100	950	750
90	820	715
80	750	720

—A. S.

Pickling Solutions; Influence of Arsenic in — C. F. Burgess. Amer. Electrochem. Soc. Sept., 1905. [Advance Proof.]

It has long been known that the addition of arsenic to a sulphuric acid pickle renders it much less active. The author has made some comparative experiments on the action of 5N sulphuric acid, pure and mixed with less than 1 per cent. of arsenic as trioxide, upon steel springs. The pure acid dissolved in an hour 34 times as much iron as did the impure acid. In the first twenty minutes the ratio of the two rates was 9:1, in the last forty minutes 94:1.

Acid solutions exert a weakening influence on steel apart from the thinning due to solution; they render the metal brittle, an effect supposed to be due to the penetration of hydrogen into the metal. Experiments were made on steels in the manner described above, and the weakening was measured by comparing the angle through which the steel could be sharply bent before breaking, before and after treatment; in all cases the arsenic exerted a marked influence in diminishing the weakening effect of the acid solution—the effect of the arsenical acid was from 1/7 to 1/60 of that of the pure acid. Similar but smaller differences were observed when sulphuric was substituted for hydrochloric acid. Steels pickled in the pure and the arsenical acid and then nickel-plated showed similar differences, a weakening of 7.2 per cent. with the arsenical, of 15.6 per cent. with the pure acid.—J. T. D.

[Lead Smelting] Process at Friedrichshütte; Huntington-Heberlein — A. Biernbaum. Z. Berg-Hütten. u. Salinenwesen im Preuss. Staate, 1905, 53, 219—230. Eng. and Mining J., 1905, 80, 535—538.

At the present time at the Friedrichshütte in Upper Silesia, all kinds of lead ore, with the exception of a low-

grado concentrate containing from 25–35 per cent. of lead, are treated by the Huntington-Heberlein process (see Eng. Pats. 8064 of 1896, 3795 of 1897, and 13,454 of 1903; this J., 1897, 543, 683; 1901, 794). The author discusses in detail the cost and advantages of this process as compared with the older methods of lead smelting. Among the advantages of the process are stated to be—decreased cost of labour and fuel, smaller production of lead fume, non-interference of the zinc contained in the ores, and increase of the yield of lead and silver by 6–8 per cent.—A. S.

[Gold] Ores; Combined Apparatus for Grinding or Crushing, Washing and Separating —. R. Stanley, Nuneaton, Warwickshire. Eng. Pat. 24,386, Nov. 10, 1904.

THE mineral is reduced to a fine powder by several sets of rolls and then falls on to a travelling belt of gauze which dips into a trough of water and then passes beneath a water-spray. The finer portion of the material is forced by the water-spray through the gauze belt and falls into the trough, whilst the coarser portion remaining on the belt is returned to the finishing rolls. Separators and elevators of various kinds may be used with or without mercury in their respective sumps.—J. H. C.

Zinc; Impts. in Furnaces or Apparatus for —. J. Armstrong. Eng. Pat. 20,543, Sept. 23, 1904.

THE furnace consists of a number of narrow, tall reducing chambers formed with relatively thin walls and surrounded by heating flues. The flues are heated by compressed gaseous fuel burned with the aid of compressed air in injector burners arranged at the bottom of the flues. A supply of secondary heated air from flues disposed in the brickwork of the furnace is also introduced into the heating flues, being drawn in by the partial vacuum produced by the burning gaseous fuel. The zinc ore together with the carbon necessary for reduction is fed in continuously at the top of the reducing chambers, and the residue is withdrawn continuously from the bottom. The zinc fumes pass through gills or ducts into condensing chambers alongside the reducing chambers, the latter being sealed against admission of air by the charge of ore and carbon at the top and by the residual ore at the bottom.—A. S.

Furnaces; Roasting —. H. E. Newton, London. From F. J. Falding, Brooklyn, U.S.A. Eng. Pat. 6931, April 1, 1905.

Copper Mattes; Conversion of —. C. M. Allen, Butte, Montana, U.S.A. Eng. Pat. 8387, April 19, 1905.

THE walls of the converters in which copper matte is Bessemerised are constructed of heavy metal pieces or blocks, the heat conductivity and capacity of which are sufficient to maintain the inner surface of the converter at a temperature below that of the molten bath, but above that at which any considerable chilling of the bath will occur.—A. S.

Nickel Ores, or other Material Containing Nickel; Treating with Carbonic Oxide —, and Apparatus therefor. C. Langer, Ynyspenllweh, Glamorgan. Eng. Pat. 13,351, June 28, 1905.

IN the extraction of nickel, according to the process described in Eng. Pat. 12,626 of 1890 (this J., 1891, 774), it is stated that the treatment with carbon monoxide may be carried out at temperatures ranging from 0° to 150° C.

It is now found that in order to obtain good results the temperature must be kept between 40–50° C. To effect this purpose a modified form of the apparatus described in Eng. Pat. 23,665 of 1895 (this J., 1895, 47) is used. It consists of superimposed chambers, each having a partition and a bottom. A fluid is caused to pass through passages within the apparatus for the purpose of keeping the temperature of the material between 40° C. and 50° C. J. H. C.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(A.)—ELECTRO-CHEMISTRY.

Chlorates; Determination of —, and *Calculation of Yield in the Electrolytic Chlorate Industry*. M. Coukeru. Chem.-Zeit., 1905, 29, 1072–1074.

WHILE a few years ago the yield of chlorate by electrolytic processes on the industrial scale was about 60 per cent. of the theoretical, and represented about 30 per cent. of the energy furnished, the corresponding figures now are about 90 and 65 respectively. Chlorate in the liquors is determined either by direct chemical or by indirect chemical or physical methods. The usual chemical method consists in boiling a measured volume of the solution with acidified solution of ferrous sulphate, and determining the excess of ferrous sulphate by permanganate; the ferrous sulphate is standardised upon a solution of pure potassium chlorate of known strength. The indirect methods are based on determination of the composition of the evolved gases; if the whole current is producing chlorate, hydrogen only is evolved; if no chlorate is produced, the gas contains 33·3 per cent. of oxygen, and from the actual percentage of oxygen in the gas the proportion of the total current yielding chlorate

is easily calculated. The oxygen may be determined by the usual endiometric methods, or calculated from the specific gravity of the dried gas. The latter is the more accurate method, for by weighing a litre a difference in weight of 1 mgrm., easily within the power of an ordinary balance, is produced by a variation of 0·2 per cent. of oxygen. The Lux gas-balance can even be arranged so as to register continuously the specific gravity, and hence the percentage current yield. Assuming 2·5 volts to be the minimum or theoretical potential difference between the electrodes, the "current-yield" and "energy-yield" are given by the following formulæ:—

$$\text{Current-yield} = \frac{100y}{ax} \quad \text{Energy-yield} = \frac{100y}{evx}$$

where x is the number of ampère-hours, y the amount of chlorate produced in grms., v the potential difference at the electrodes, and a and e are coefficients per ampère-hour and per watt-hour respectively, having the following values:—

	a .	e .
	GRMS.	GRMS.
Potassium chlorate	0·7635	0·3054
Sodium chlorate	0·6640	0·2656
Barium chlorate	0·9485	0·3794

The determination of the chlorate by weighing the gas affords a ready and very useful control of the process, but it must be remembered that the composition of the gas is influenced by various circumstances, such as temperature, alkaline reaction of the electrolyte, reduction of the chloride-content below a certain point by addition of chromate, calcium or magnesium salts, &c., and consequent variations in the production of hypochlorite. These factors must be considered in interpreting the results of the tests.

A table in the paper gives, for current-yields rising from 60 to 100 per cent. by steps of 2½ per cent., the percentage of oxygen in the gases, the weight of a litre at N.T.P., and the amounts of sodium and of potassium chlorate furnished per H.P. day for each 0·1 volt between 3·0 and 4·0 volts, with the corresponding theoretical energy-yields.—J. T. D.

Platinum; Electrolytic Solution of ——. R. Ruer. Z. Elektrochem., 1905, 11, 661–681.

A CONTINUATION of the author's earlier researches on the behaviour of platinum in solutions of sulphuric acid, when subjected to the action of an ordinary alternating current. Under these conditions, the platinum electrode does not dissolve, but undergoes a change of the metal surface to the spongy state, the thickness of this sponge being dependent upon the current density used. In order that solution of the platinum may occur, it is necessary, either that the anodic component of the alternating current should preponderate, or that oxidising agents should be present to complete the reaction before the cathodic component of the alternating current have time to become active. The present research was carried out to prove the correctness of this theory, and to show that the anodic component of the alternating currents could be replaced by a suitable oxidising agent, and the cathodic component by a suitable reducing agent, without producing any change in the results observed. The method of observation adopted was to allow a relatively long period to elapse between each electrical current impulse at the anode and cathode respectively, during which time the various oxidising and reducing chemicals employed were allowed to act upon the anode and cathode. The electrolyte used was a 50 to 66 per cent. solution of sulphuric acid, and this was contained in a U-tube having an anode of 30 sq. cm., and a cathode of 1 sq. cm. superficial area respectively, both made from absolutely pure platinum. The electrical circuit was completed by an ampère-meter, a resistance box, a primary battery, and a rotary circuit breaker, provided with two points of contact. The results obtained

by the author in this research are summarised at the conclusion of his paper. These prove that his theory of the action of alternating current upon platinum in sulphuric acid solutions is correct. The potential at the anode must be over 1.20 volts before solution can occur.

Gas Battery. P. G. L. Noel. Fr. Pat. 350,100, Aug. 4, 1904.

THE battery consists essentially of a series of hydrogen electrodes and oxygen electrodes, formed of hollow plates of palladium-asbestos, hydrogen gas and oxygen gas being supplied to the interiors of the alternate hollow plates, the whole being immersed in an electrolyte consisting of a 15–20 per cent. solution of caustic potash. The hydrogen (or oxygen) gas is occluded on the inner face of the palladium, diffuses through to the outer face, and there combines with the oxygen (or hydrogen) from the adjacent electrode, with formation of water and generation of an electric current. Each electrode is constructed of two

parallel grids, spaced apart by a frame, and having the openings in the grids covered by shallow perforated boxes containing sheets of palladium-asbestos; the gas is admitted into the space between the two grid. The alternate electrodes are separated by means of corrugated sheets of perforated ebonite. A number of electrodes and separators, having communicating passages for the gases and electrolyte, are bolted together to form the battery.—H. B.

Battery; Electric —, with Liquid Chlorine [Depolariser]. E. Buhot. Fr. Pat. 356,551, May 23, 1905.

THIS invention relates to a rotating electric battery, in which chlorine, stored in the liquid form, acts as the depolariser. The battery consists essentially of two vessels, joined together on the axis of rotation by a tube provided with a stop-cock. One vessel contains the liquid chlorine, and the other is partially filled with the electrolyte of dilute hydrochloric acid, into which dip the electrodes consisting of discs placed perpendicularly to the axis of rotation. The negative electrode of iron or zinc divides the electrolytic cell into two parts, which are in communication by openings in the electrode near to its outer edge. On each side of the negative electrode are arranged the positive electrodes of platinised silver, or carbon, bound together, and furnished with slits, one edge of each slit being turned towards the front of the plate and the other towards the back, this arrangement facilitating the renewal of the liquid between the electrodes. During the rotation, the different parts of the electrodes pass successively into the electrolyte and into the gas, and at the same time chlorine is slowly admitted, this gas combining with the liberated hydrogen and preventing polarisation. The current is conveyed away in any suitable manner, as, for instance, by means of mercury cups.—B. N.

(B.)—ELECTRO-METALLURGY.

Steel; New Gin Process for the Electrical Manufacture of —. G. Gin. Amer. Electrochem. Soc., Sept., 1905. [Advance Proof.]

IN the process described, the formation of arcs in the slag above the bath of metal serves as the chief source of heat.

As shown in the figure, the furnace is divided into three compartments. In compartment 1, the crude metal is refined by being heated in contact with iron ore and, if phosphoric lime is also employed. The dissolved oxide is removed in compartment 2, in which also the metal is re-carburised. The third compartment serves to finally adjust the carburisation or to incorporate any special constituents of the steel.

The chambers communicate through the passages B which are below the slag line. The electric current passes into the furnace through carbon electrodes, which dip into the slag in chamber 1, and passing through the metal, leaves the furnace by the electrodes in 2 and 3, which are electrically in parallel. The passage of metal from one chamber to another, as also the tapping from the furnace by the outlet D, is effected by immersion of the electrodes and the consequent raising of the level of the metal.

—R. S. H.

Bullion; Electrolytic versus Sulphuric Parting of —. F. D. Easterbrooks. Amer. Electrochem. Soc., Sept., 1905. [Advance Proof.]

By the sulphuric acid method of parting, gold can be produced ready for shipment in 24 to 30 hours, whilst the electrolytic method requires several days for production of refined gold. This gain in time is advantageous when interest charges have to be considered. The acid process, however, entails a loss of acid in the parting kettles, and the non-elimination of the tellurium present in the bullion. The author gives photographs of silver alloys, to show the effects of the presence of this metal in rolling and minting operations with the silver-copper alloy used for coins. The electrolytic process entirely removes this impurity from the silver. The Balbach and Moebius vats for electrolytic refining are described in detail. The former is stated to be the simpler of the two in construction and operation. An electrolytic parting plant is to be preferred, on the grounds of neatness and cleanliness of operation for refining silver bullion, but as regards gold bullion, the author considers the electrolytic processes, such as the Wohlwill process, too expensive and slow in operation to come into general use, excepting when platinum is present in paying quantities in the metal alloy which is to be refined.

—J. B. C. K.

Silver; Electrolytic Process for Refining —. A. G. Betts. Amer. Electrochem. Soc., Sept., 1905. [Advance Proof.]

THE Moebius and Balbach processes for refining silver by electrolysis, according to the author, are open to objection, since they require the enclosure of the anodes in cloth bags, the collection of the deposited silver in a loose condition and also demand a high E.M.F. and the use of ungainly apparatus. The presence of lead and bismuth in the bullion also causes loss, since these metals are not recovered in a marketable form. The author, after many experimental trials with various acids, has found that methyl-sulphuric acid prepared at a temperature of about 100° C., gives excellent results as solvent for the anodes, and that the quality of the deposit of silver obtained from this solution can be improved by use of carbon bisulphide in the bath. The deposits of silver obtained with this acid, were hard and solid, and free from any tendency to form trees. Lead, copper and bismuth go into solution with the silver at the anode, while gold, selenium and tellurium remain undissolved.

The three first-named metals can be separated and recovered from the solution by chemical substitution—and the silver salt of methyl-sulphuric acid can be re-formed for further use in the bath.—J. B. C. K.

Antimony; Notes on the Electro-Metallurgy of —. A. G. Betts. Amer. Electrochem. Soc., Sept., 1905. [Advance Proof.]

CRUDE antimony can be purified by treatment with ferric chloride solution to form ferrous chloride and antimonious chloride, and subsequent electrolysis with carbon anodes and lead cathodes. On electrolysis, the ferric chloride formed at the anode flows down to the bottom of the cell, and is drawn off, whilst fresh antimony solution is introduced at the top. With a cathode area of 65 sq. in. and anode area of 60 sq. in., 3 to 4 ampères at about 1.2 volts give a current efficiency of 90 per cent.

Antimony fluoride solutions are preferable to those of the chloride for the refining of the metal, and yield a very good cathode deposit.—R. S. H.

Aluminium; Use of —, as a Reducing Agent. O. P. Watts. Amer. Electrochem. Soc., Sept., 1905. [Advance Proof.]

SOME metals, like titanium and tungsten, cannot be obtained in the pure state by reduction of their oxides with aluminium powder, as the reaction does not evolve sufficient heat. Addition of ferric oxide to the charge supplies the heat necessary for the reduction, but the metals are then obtained as alloys ferro-titanium or ferro-tungsten. The author finds that Goldschmidt charges can be fired with safety in an electric arc furnace, by adding fluorspar or cryolite to lessen the violence of the reaction in the case of more easily reducible oxides; in

this way titanium or tungsten can be reduced. The charge was put into a furnace lined with magnesite, the cover put on, and an arc started just above the charge; for five minutes 300 ampères at 80 volts were used, then for five minutes 600 ampères at 80 volts. Quantities up to 350 grms. of aluminium were used. Probably the heat of the arc can be used as a supplementary supply in all cases where hitherto an easily reducible oxide has been added for that purpose.—J. T. D.

Metals from Solutions of their Sulphates; Cathode Potentials necessary for the Electrolytic Separation of —. G. Cofetti and F. Foerster. Ber. 1905, 38, 2934—2941.

PREVIOUS determinations of the equilibrium potential of metals of the iron group against solutions of their simple salts differ widely in the results obtained. The authors have carefully measured the potential required to effect separation of a number of metals—including iron, cobalt and nickel—from solutions of their sulphates. The apparatus consisted of an electrolytic cell containing a $N/1$ solution of the sulphate, with an anode of the pure metal under examination, and a cathode of platinum, 0.5 mm. thick, the edges and one face of which were covered with shellac. In the case of cadmium the electrolyte also contained 10 per cent. of hydrofluosilicic acid to prevent the uneven deposition of the metal. The E.M.F. of the cathode was measured by means of Ostwald's capillary electrometer, at various current densities, which were in each case maintained constant for some time.

From the results obtained it appears that the potential required for separation of iron, nickel, and cobalt is intermediate in value between the potentials required for separation of cadmium and zinc respectively. In view of the high "back E.M.F." of hydrogen against the latter, the authors consider the above an explanation for the fact that iron is not deposited quantitatively from a weak acid solution.—B. J. S.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

Para Rubber Seed Oil. L. Wray, Malay Mail; through Chem. Rev. Fett- u. Harz-Ind., 1905, 12, 250.

THE average weight of 1000 deoiled and sun-dried seeds of the Para rubber plant is 2.043 kilos. They contain about 40 per cent. of oil, and 1000 kilos. of the dried seeds yield about 437 litres of oil. A single tree usually bears more than 1000 seeds, but there is a small-leaved variety, which produces no fruit at all. The seeds must be expressed immediately after drying and crushing, since otherwise the oil becomes dark and turbid.—C. A. M.

FRENCH PATENTS.

Oil from Oleaginous Matters; Process for the Continuous Extraction of — A. Smits. Fr. Pat. 354,229, May 13, 1905.

THE substance to be extracted is placed in a series of vessels in connection with one another. The solvent is conducted from a tank to the bottom of the first vessel, and, after percolating through the material, is drawn off from the top and passed down a pipe to the bottom of the second vessel, and so on. From the last vessel the solvent and oil are drawn off from the bottom, led through cooling pipes, then into a chamber where any water is allowed to settle, and finally pumped up to a distilling apparatus. The solvent evaporated from the latter is condensed and allowed to flow back into the solvent tank. When a charge of material is almost completely extracted, the connection between the last chamber and the cooling apparatus may be closed and the solvent, which will now contain but little oil, is run off from the bottom of the vessels and pumped into a second tank for use in extracting a further charge of material.—W. P. S.

Fats, Oils, Resins and Hydrocarbons; Purification of — C. Fresenius. Fr. Pat. 354,810, May 17, 1905.

THE formation of an emulsion during the treatment of oils, &c., with alkalis or alkaline-earths may be prevented by keeping the temperature of the mixture at about 85° C. and performing the operation under pressure in an atmosphere of an inert gas. The high temperature unavoidably produced by steam pressure is thus done away with.—W. P. S.

(A.)—PIGMENTS, PAINTS.

Lampblack and Graphite from Acetylene and Metallic Carbides. A. Frank. Versamm. Ges. deutscher Naturforscher u. Aerzte, Sept., 1905. Chem.-Zeit., 1905, 29, 1044.

If acetylene mixed with carbon monoxide or carbon dioxide be decomposed by explosion, the carbon of both gases is

deposited in a pure form, free from tarry condensation products, $C_2H_2 + CO = 3C + H_2O$. The lampblack so obtained is superior to the best American varieties in blackness and covering power. If carbon monoxide or carbon dioxide be allowed to act on carbide of the alkalis or alkaline-earths at a high temperature, the carbon separates in the graphitic form, $CaC_2 + CO = 3C + CaO$. After the removal of the oxide a graphite remains almost free from ash, and suitable for electro-chemical and chemical purposes. It is similar in properties to Acheson graphite. Other elements which will combine with the metal of the carbide can be used in place of carbon monoxide. It has been shown that at the moment when the carbon is liberated, it is readily taken up by metals. Iron, for instance, when packed with carbide in a muffle and treated with carbon monoxide or dioxide, undergoes hardening and cementation. Silver dissolves carbon under these circumstances and becomes blackened.—F. S.

ENGLISH PATENT.

Lakes [from Azo Dyestuffs]; Manufacture of New Colour — H. E. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 28,150, Dec. 22, 1904.

Paint; Simultaneous Employment of Cupric Thiocyanate [Sulphocyanide] and Arsenious Acid in Submarine — C. Dubois. Fr. Pat. 354,618, March 1, 1905.

IT is claimed that the simultaneous addition of cupric thiocyanate and arsenious acid to paints, intended for the hulls of ships, confers on these a far higher degree of preservative efficacy than the use of either of these substances alone.—M. J. S.

Lakes [from Azo Dyestuffs]; Process of Producing Red — Act.-Ges. f. Anilinfabr. Fr. Pat. 354,649, May 25, 1905.

THE barium, aluminium, or other salts of the dyestuff obtained by combining diazotised *o*-chloro-*p*-anisidine or *o*-chloro-*p*-phenetidine with β -naphtholdisulphonic acid R, when precipitated on a substratum, produce brilliant bluish-red lakes, very fast to light.—T. F. B.

Lakes [from Azo Dyestuffs]; Process of Producing Orange or Yellowish-Red — Act.-Ges. f. Anilinfabr. Fr. Pat. 354,676, May 26, 1905.

THE diazo derivative of *m*-chloroaniline sulphonic acid ($NH_2 : Cl : SO_3H = 1 : 3 : 6$) is combined with β -naphthol. By precipitating this dyestuff on a suitable substratum in the usual manner, orange or yellowish-red lakes are obtained, which are very fast to light, and quite insoluble in water and oil.—T. F. B.

(B.)—RESINS, VARNISHES.

Copal (Java Copal); A New Fossil — K. Dieterich. Versamm. Ges. deutscher Naturforscher u. Aerzte, Sept. 1905. Chem.-Zeit., 1905, 29, 1047—1048.

THIS fossil copal is found in Java associated with lignites

and pyrites. It is more or less transparent, with a yellow to greenish-brown colour. It melts completely at 178° C., and its sp. gr. varies between 1.033–1.041. It contains sulphur derived from minute fragments of the pyrites, but no nitrogen. The amount of ash is 2.44 per cent., and water 0.265 per cent. It contains no bitter substances, essential oils or volatile acids. The acid value was 4.55–5.07; saponification value, 14.54–18.03; iodine value, 50.36–54.66. It is very slightly soluble in alcohol, easily soluble in chloroform, benzene and carbon bisulphide. It is only slightly soluble in chloral hydrate, thus proving to be a true copal. On destructive distillation, it yielded the following fractions:—I.—120° C. had a refractive index of 1.4803–1.4812. Fraction II. at 280° C. was a brownish-yellow oil, amounting to 15.67 per cent. of the copal, with refractive index 1.5116; sp. gr. 0.921; iodine value 87.24–96.53. Fraction III. 280–300° C., amounted to 22.61 per cent., with sp. gr. 0.928, and iodine value 113.48 to 120.74. Fraction IV. 300°–360° C., was a dark oil, amounting to 19.03 per cent.; sp. gr. 0.920; iodine value 98.10–120.68. Fraction V., 12.93 per cent., was a viscous greenish-brown oil, sp. gr. 0.9805; iodine value 42.68. The Java copal, being a true fossil copal, appears to be quite distinct from the Manila copal.—F.S.

Sodium Nitrate; Transformations of — in the Soil of Sugar-Beet Plantations. J. Stoklasa. Z. Zuckerind. in Böhmen, 1905, 30, 1–8.

PRACTICAL observations have shown that, in fertilising sugar-beet crops with sodium nitrate, very little of the fertiliser is washed away in normal weather, but that the nitrogen remains available in the humus of the top soil. This result is due not only to the ease with which nitrate nitrogen is directly assimilated by the growing beet-root, but also to various biological processes which go on side by side in the humus of the soil. These changes, brought about by the lower organisms of the

soil, are mainly:—(1) Reduction of the nitric acid to ammonia, and (2) oxidation of the ammonia to nitrous and nitric acids. In the course of all these processes nitrogen is fixed in the organic form, *i.e.*, in the living protoplasm of the multiplying bacteria. (3) The nitric acid of the sodium nitrate is assimilated directly by algae and fungi, and is converted into organic form. (4) The organic nitrogen of the lower organisms and the root-residues of the beets and various weeds is converted into ammonia or nitric acid. There is thus a cycle of changes and a continuous conversion of the nitrogen of the nitrate in the soil under the action of the lower organisms. Not only is the nitrogen of the nitrate directly assimilated by the higher plants and the lower organisms, but it considerably intensifies the vital processes of the cells and takes part in the oxidation of the carbohydrates. The activity of the organisms which enrich the soil in nitrogen is stimulated, and an increase of the nitrogen in the top layer of humus which contains the micro-organisms is observed, whilst the under soil never contains more than half the proportion of nitrogen which is found in the humus.—J. F. B.

Fertilisers; Availability of Mixed — W. F. Sutherst. Chem. News, 1905, 92, 185.

From experiments carried out by the author, it seems that by mixing certain fertilisers the availability increases in some cases and decreases in others. Equal quantities of the materials mentioned below were mixed, and, after moistening with water, were allowed to stand for three weeks, when the citric acid soluble phosphoric acid was determined. The results obtained, expressed as calcium phosphate ($\text{Ca}_3(\text{PO}_4)_2$), were:—

Bone-meal alone	29.06 per cent.
" + potassium chloride	"
" ("muriate of potash")	26.54 "
" + kainite	23.99 "
" + salt	25.85 "
Bone-flour alone	43.45 "
" + ammonium sulphate	44.51 "
" + potassium chloride	"
" ("muriate of potash")	49.06 "
" + kainite	47.97 "
" + common salt	45.80 "
" + sodium nitrate	67.70 "
" + salt + sodium nitrate	44.77 "

Sugars, Polyhydric Alcohols and Hydroxy Acids, Influence of Lead and Bismuth Salts on the Rotatory Powers of —. H. H. Grossmann. Z. Ver. dent. Zuckerind., 1905, 55, 911—976.

SALTS of the heavy metals, especially lead and bismuth, react with hydroxylated compounds in presence of alkali, causing the replacement of the hydrogen of one or more of the alcoholic hydroxyl groups by PbO or BiO. In the case of optically active compounds, this reaction is accompanied by very profound modification of the specific rotatory power, the change being further complicated by the influence of the excess of alkali which is necessary to redissolve the precipitate of heavy metal compound at first produced. In the case of lead salts the change is frequently associated with an actual inversion of the sign of the optical rotation, *e.g.*, in the well-known case of levulose, in which levo-rotation may be changed to the dextro-rotation which increases up to a maximum point and then changes back again as the proportion of lead is increased. The author has studied the action of lead acetate and nitrate in varying proportions in presence of more or less excess of caustic soda upon the rotatory powers of a large number of sugars and other compounds of the above type. The alkali-lead compounds of the hexoses are not very stable, since the free alkali tends to produce after a short time the isomeric redistributions studied by L. de Bruyn.

The action of bismuth was investigated in the form of a solution of bismuth nitrate in aqueous glycerol. The alkali-bismuth tartrates are particularly interesting; there appear to exist two series of these compounds—one, stable only in acid solutions, very strongly levo-rotatory, and the other very powerfully dextro-rotatory. Of the sugars, only levulose appears to be profoundly modified in its optical properties by the bismuth salt; the smaller depressions of the rotatory powers observed with the other sugars are attributable rather to the influence of the excess of alkali than to that of the bismuth.—J. F. B.

Barley; Extract Determinations in — [Season 1904—5].
A. Reichard and G. Farucker. Z. ges. Brauw., 1905,
28, 677—682.

THE authors summarise their general conclusions from the analysis of a large number of samples of barley and the malt prepared therefrom. In the analyses of the past

solid media with agar-agar, to which dextrose and mineral salts had been added, and streaks were made on plates by means of a brush of each of the yeasts and fungi studied, each culture occupying the same relative position on the different plates. In this manner, 15 yeasts were tested on 15 plates, and the assimilability of the various nitrogenous products by the different species was judged by the vigour of the colonies developed. The following table shows the results obtained from nine of the more important species tested:—

No. in Berlin collection.	Species of Yeast or Fungus.	Tyrosine.	Leucine.	Alanine.	Hypoxanthine.	Histidine (chloride).	Uracil.	Asparagine.	Aspartic Acid.	Arginine.	Guanidine (hydrochloride).	Lysine.	Choline.	Thymine.	Potassium nitrate.	Ammonium sulphate.

season, the values obtained for the barley extracts were compared with those for the malt extracts by taking into account the loss of weight sustained in malting. The quantity of malt extract, calculated on 100 parts of the barley extract, thus becomes an important factor in the valuation of barley, provided the conditions of malting be known and standardised.

The percentage of extract in barley decreases as the percentage of protein increases; the percentage of extract in malt is, as a rule, proportional to the percentage of extract in the barley. From the percentage of protein in the barley a conclusion may be drawn as to the relative percentage of extract in the malt. Under determined conditions of malting, the yield of malt extract can be calculated from the percentage of extract in the barley. The quantity of malt extract obtainable from 100 parts of barley extract decreases, as a rule, as the loss of weight in malting increases. The percentage of sinker corns in the malt, is, to a certain extent, a measure of the degree of modification of the endosperm, and has, therefore, an influence on the availability of the extract in the malt. A very low proportion of sinkers indicates high availability but low proportion of extract, i.e., "forcing." The most advantageous proportion of sinkers appears to be 15—22 per cent. The ratio of the price per unit of barley extract to the price per unit of wort extract obtained, becomes more unfavourable the higher the loss of weight in malting. If this ratio be worked out for each percentage of malting loss, the cost of the malt extract of the wort can be calculated at the time of buying the barley.—J. F. B.

Beer Yeast; Assimilability of the Autodigestion Products of — by Different Species of Yeast and Fungi. I.
P. Lindner, Rülke and H. Hoffmann. Woch. f. Brau., 1905, 22, 528—530.

IN the case of yeast, the aggressive nourishment of stronger cells at the expense of the substance of their weaker neighbours has not been observed, but the utilisation of the autodigestion products of aged or dead cells by the vigorous survivors in old droplet cultures, fully exhausted of sugar, is a well-known fact. The authors have taken advantage of the isolation and purification of the various nitrogenous products of the autodigestion of beer yeast by Schenck (this J., 1905, 555) to study the assimilability of each of these substances separately for the nutrition of cultures of various species of yeast and allied organisms. This question has a practical bearing on the employment of yeast products as nutrients for the yeast in distillery fermentations, &c. The study also shows that the metabolic products are not to be regarded as yeast poisons, but in most cases as actual foods.

The various purified substances were incorporated in

It would appear that the autodigestion products are most readily assimilated by the aërophilic fungi with little or no fermentative capacity, also by the culture yeasts and most of the wild after-fermentation yeasts, but not by *S. exiguus*, *Logos* yeast, fission yeasts, *S. apiculatus* and *Ludwigii*.—J. F. B.

Yeast; Nitrogenous Nutrition of —. A. Fernbach.
Ann. de la Brasserie; through *Brewers' J.*, 1905, 41, 620

THE author emphasises the fact, first mentioned by Duclaux 40 years ago, that yeast cells may have a dual existence, viz., (1) as simply vegetative organisms, and (2) as ferments the special function of which is the decomposition of sugar into alcohol and carbon dioxide. In a study of the nutrition of yeast, these two functions must be examined separately, in order to ascertain whether any particular food stimulates chiefly the vegetative or the fermentative function. The author discusses the results which have been obtained by various workers, and points out the need of investigating the alterations sustained by the nitrogenous constituents of barley and malt. For if these transformations can be brought under control, so that any given character of wort can be produced at will, it should be possible to impart predetermined characteristics to the fermentation process and to the resulting yeast crop.

—A. S.

Aromas. Specific; Production of — in Fermentation.
T. Bokorny. Zentralbl. f. Bakt.; through *Brewers' J.*, 1905, 41, 629.

IN the fermentation of concentrated sugar solutions pitched with large proportions of beer yeast, different aromas can be produced by varying the conditions. In one instance, the flavour and aroma of Malaga wine were produced, whilst in another the odour strongly resembled that of toast. The production of aroma is attributed to the formation of ethers during fermentation. The odour and flavour of Malaga developed only after a considerable time, and are probably due to a special reaction of moribund zymase. The production of the toast odour is observed chiefly in the case of strong solutions of sugar, pitched with a large quantity of yeast, and exposed to a temperature of 30°—40° C. It is due to the action of zymase, since it is not observed when there is no fermentation—for example, when fermentation is rendered impossible by the use of excessively concentrated solutions of sugar, or when sugar is absent. The odour is produced to a greater degree when the zymase is in an enfeebled condition, than when it is in a normal state.—A. S.

Enzymes; Behaviour of — towards Colloidal Solutions. Reiss. *Beiträge Chem. Physiol.*; through Brewster's J., 1905, 41, 624.

The author finds that rennet and trypsin when shaken with a solution of lecithin in chloroform are dissolved to some extent by the latter. These enzymes mentioned are not dissolved by other solvents, and it is therefore concluded that the chloroform-lecithin solution is colloidal, and that the enzymes pass from their aqueous solution or suspension into this colloidal liquid. The catalase present in milk behaves in an exactly opposite manner. It adheres to the milk globules, being found more abundantly in cream than in skimmed milk, but if the globules are separated, and then suffused with water or "physiological" salt solution, the enzyme passes into the liquid almost completely. In this case, therefore, the colloids of milk plasma precipitate the enzyme, which is readily soluble in non-colloidal liquids.—A. S.

ENGLISH PATENT.

Brewing [Hopping Beer]; Impts. in —. H. W. Gates, Sheffield. Eng. Pat. 25,774, Nov. 26, 1904.

THE beer is charged with hops during the process of fermentation by lowering a vessel with perforated walls, filled with raw hops, into the fermentation vessel and pumping the beer from the bottom of the fermentation vessel into the top part of the hop cylinder, so that it percolates through the hops back into the fermentation vessel. In cases where it is not desirable to pump the fermenting beer, the hops may be packed in a perforated cylinder fitted up so as to serve as a rouser, which is stirred about in the beer during fermentation. The used hops are suitable for employment in the wort copper for extraction by boiling wort.—J. F. B.

FRENCH PATENTS.

Beer; Preparation of a Product for Hopping —. G. Ronnberg and Co. Fr. Pat. 354,160, May 10, 1905. Under Int. Conv., April 25, 1905.

THE lupulin of hops is collected in the pure state and is mixed with a saccharine substance, e.g., cane sugar, invert sugar or glucose, but preferably with dextro-levulose. This mixture is incorporated with the beer and is intended to supersede the addition of raw hops to the beer in cask, which is liable to introduce micro-organisms and other undesirable matters.—J. F. B.

Condensers, Coolers, &c., employed in Distilling and other Industries; Impts. in —. E. Guillaume. Fr. Pat. 354,402, May 18, 1902. I., page 1101.

Wines and Spirits; Artificial Ageing of —. *Process and Apparatus for the Oxidation and Esterification of Oleaginous and Alcoholic Liquids.* M. E. Pozzi-Escot. Fr. Pat. 354,747, May 29, 1905.

THE apparatus consists of a catalytic-oxidising vessel ["oxydateur-catalysateur"] and an esterifying-pasteurising vessel. The liquid contained in a reservoir is fed under pressure through a jet, which aspirates air during the passage of the liquid, into the top of the oxidising column. This column contains a number of metallic baskets filled with catalytic materials, one of the most suitable being platinised asbestos. The temperature of oxidation is regulated by a water-jacket surrounding the column. The bottom of the column is connected with the esterifying vessel which consists of a worm of small diameter surrounded by a steam chamber. The liquid and vapour issuing from the esterifying worm are cooled and condensed by passing through a worm condenser, and the gases which escape condensation in this are further

cooled by a worm surrounded by a freezing mixture. For the treatment of oils, the esterifying-pasteurising vessel is omitted.—J. F. B.

Amyl Alcohol; Manufacture of —. E. A. Mishra and L. Lewin. Fr. Pat. 354,807, May 16, 1905.

CERTAIN bacteria exist which are capable of transforming sugar or maltose into amyl alcohol. Cultures of these bacteria are prepared, for example, from the must of prunes, and introduced into a wort prepared from potato or grains, and containing 1–2 per cent. of alkali. After fermenting for 120–150 hours, the liquor is distilled at 136°–140° C. (See this J., 1904, 121, 876 and 1107; and 1905, 683.)—F. S.

(A.)—FOODS.

Yeast; Determination of Dough-Raising Power of Bakers' —. M. Silberberg. Z. Spiritusind. 1905, 28, 388–389.

THE author bases his argument on the principle that the value of a yeast for bakers' purposes is inversely proportional to the specific gravity of the bread made with it, and contends that none of the methods hitherto proposed for the valuation of bakers' yeast yield results in accordance with this principle. These methods deal only with the rate of evolution of gas from a dough or sugar solution at a temperature of 30° C., and relate, therefore, only to the dough stage of the manufacture of bread. They take no account of the subsequent activity of the yeast in the oven, at a stage which is of the greatest importance in determining the volume, shape and structure of the loaf. The fermentation at this stage depends on the fermentative power of the yeast at high temperatures and under the pressure occasioned by the formation of the crust, also upon the temperature at which the yeast ceases to be active. The author has examined, comparatively, a beer yeast and a pressed yeast by the method described by Pollack (this J., 1904, 452). He found that the beer yeast was the more active in the dough fermentation stage and raised the dough to a larger volume in the first half-hour than the pressed yeast. After two hours, when the diastatic enzymes of the yeast had exerted their activity, the volumes of the dough with the two yeasts were practically the same. Incidentally it was observed that in this process, at 30° C., the dough continued to rise for about four hours, after which it slowly subsided. But in the practical bread-making experiments, the beer yeast was found to give a very inferior product on account of its feeble fermentative activity in the oven. The loaves with the beer yeast had a flattened shape, poor appearance and small volume, whilst the loaves with the pressed yeast were in every way satisfactory, and had a volume from 9 to 23 per cent. greater than the others. Similar results were obtained by other methods in use for the determination of dough-raising power, all indicating the superiority of beer yeasts which gave poor results in practice; consequently the author concludes that the only reliable test for bakers' yeast is an experimental baking, combined with a determination of the volume of the loaves.—J. XIX.—PAPER, PASTEBOARD, Etc.

Cellulose [Copper Compound]. H. Riesenfeld and F. Taurke. Ber., 1905, 38, 2798—2800.

A SAMPLE of wood-cellulose which was insoluble in a solution of copper oxide in ammonia, as prepared by the authors, was soluble, after some time, in a solution of copper carbonate in ammonia. The solution obtained contained 1.3 per cent. of cellulose and 4 per cent. of copper. This solution deposited, on heating, a brownish-black precipitate containing the whole of the cellulose. The precipitate contained 69.7—71 per cent. of cupric oxide and 22.9—26.6 per cent. of cellulose. It is regarded as a definite compound having the approximate formula $11\text{CuO} \cdot 2\text{C}_6\text{H}_{10}\text{O}_5 \cdot 2\text{H}_2\text{O}$. It resists washing and drying at 100° C. but is decomposed by acids, which extract all the copper, it is soluble in ammonia. A similar precipitate is also formed when the cellulose solution is diluted with an equal volume of fresh copper carbonate-ammonia solution.—J. F. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

Strychnine Oxide. A. Pietet and M. Mattisson. Ber., 1905, 38, 2782—2787.

WHEN strychnine is gently heated with 10 times its weight of a 3 per cent. solution of hydrogen peroxide, it gradually dissolves, and large colourless prismatic needles of strychnine oxide separate out on cooling. This body melts with decomposition at 199° C.; it is readily soluble in hot water, and crystallises with 3 mols. of water of crystallisation; the aqueous solutions have a neutral reaction. It is readily soluble in alcohol, acetic acid and chloroform, less soluble in benzene and insoluble in ether and light petroleum spirit. Its specific rotatory power $[\alpha]_D = -1.75^\circ$. Strychnine oxide contains one atom of oxygen more than strychnine, and its general properties indicate that it belongs to the class of amino-oxides, characterised by the presence of the group: N:O. On the basis of Tafel's formula for strychnine, the oxide would have the constitution

It readily parts with its extra oxygen when heated in presence of glycerol above 100° C., and it liberates iodine from potassium iodide; it oxidises sulphur dioxide with the production of strychnine sulphate. It reacts as a mono-acidic base and its salts possess an acid reaction; they are not decomposed by ammonia.—J. F. B.

Isostrychnine. A. Bacovescu and A. Pietet. Ber., 1905, 38, 2787—2792.

ISOSTRYCHNINE is obtained when strychnine is heated with water in sealed tubes at 160°—180° C.; the strychnine is gradually dissolved and the isostrychnine separates out on cooling in the form of long needles. The same body

is also formed when strychnine acid is heated under similar conditions at a temperature of 205° C. Isostrychnine behaves as a mono-acidic base, and is the inner anhydride of isostrychnine acid, into which it is converted by boiling with an alcoholic solution of sodium ethylate. Isostrychnine crystallises with 3 mols. of water and melts without decomposition at 214.5° C. It is soluble in hot water, but only sparingly soluble in cold; the aqueous solutions have an alkaline reaction. It is readily soluble in alcohol, acetic acid and dilute mineral acids, but insoluble in alkalis. The alcoholic solution of isostrychnine is optically inactive. This body differs from strychnine in some of its colour reactions, and resembles curare rather than strychnine in its physiological effects.—J. F. B.

Yohimbine; The Methylation of Yohimboic Acid. L. Spiegel. Ber., 1905, 38, 2825—2833.

By the action of dimethyl sulphate or of methyl iodide and sodium hydroxide upon yohimboic acid (see this J., 1904, 621), a new substance is obtained which melts at 293—294° C., and which has a composition corresponding to the formula $\text{C}_{21}\text{H}_{28}\text{N}_2\text{O}_4$. This body contains no methoxy group, and the methyl group is therefore united to one of the nitrogen atoms. The author regards this body as methyl-yohimboic acid; it possesses only feebly acid properties, and the free acid can be readily crystallised from aqueous solutions of its sodium salt. Cryoscopic determinations of the molecular weights of yohimbine and yohimboic acid in acetic acid solutions indicated the formulae $\text{C}_{22}\text{H}_{28}\text{N}_2\text{O}_3$ for yohimbine, but only $\text{C}_{10}\text{H}_{13}\text{NO}_2$ for yohimboic acid. This result was apparently at variance with the analysis of the salts of yohimboic acid, which behaves as a monobasic acid with a C_{20} molecule. The author therefore considers that yohimboic acid, under the influence of acids and bases, very readily doubles its molecule, yielding the complex $\text{N}:\text{C}_9\text{H}_{12}(\text{CO}_2\text{NH}:\text{C}_9\text{H}_{12}\text{COOH})$, and that methyl-yohimboic acid possesses the constitution

The yohimbine, which was originally obtained from the plant, was probably the methyl ester of this acid, and the body now termed yohimbine, which is anhydro-yohimbine, according to the original nomenclature, is probably produced therefrom by the elimination of the elements of water, derived from the N-methyl group, and one of the adjacent oxygen atoms.—J. F. B.

Sambunigrin, a New Cyanogenetic Glucoside from the Leaves of the Black Elder. E. Bourquelot and E. Danjou. Comptes rend., 1905, 141, 598—600.

THE leaves of the black elder (*Sambucus nigra*, L.) were extracted with alcohol, the alcohol distilled off, and the residue taken up with ethyl acetate. The purified sambunigrin crystallises from ethyl acetate and toluene in long, colourless needles, with a sweetish, then bitter, taste. It dissolves in 3.5 parts of water at 20° C., is very soluble in cold alcohol, moderately soluble in wet ethyl acetate, and almost insoluble in dry ether. It has $[\alpha]_D = -76.3$, and melts at 151°—152° C. It does not lose weight at 100° C., and does not reduce Fehling's solution. It is hydrolysed by emulsin to glucose, hydrocyanic acid and benzaldehyde. It yielded 61.28 per cent. of glucose and 8.61 per cent. of hydrocyanic acid. The molecular weight by cryoscopy was 298.8. These figures agree with the formula $\text{C}_{14}\text{H}_{17}\text{NO}_6$. Fischer's mandelic nitrile glucoside, with which sambunigrin is isomeric, has $[\alpha]_D = -26.1$.—F. S.

Gentiopierin. G. Tanret. Comptes rend., 1905, 141, 207—209.

To isolate the glucoside, first discovered by Kromayer in 1862, a 17 per cent. aqueous solution of the alcoholic extract of fresh gentian root was extracted with 25 to 30 times its weight of ethyl acetate, saturated with warm water; after filtering and concentrating by distillation, a syrupy deposit was obtained, which, when exposed to the air, formed a crystalline mass. This was dissolved in an equal weight of boiling absolute alcohol, from which, on cooling, crystals of impure gentiopierin were obtained, still containing about 1 per cent. of gentin, and giving a

colour reaction with ferric chloride. These crystals were, therefore, purified by repeated recrystallisation from ethyl acetate, containing 2 per cent. of water, by which means the more soluble gentiün was eliminated. The yield of pure gentiopierin, thus obtained was from 7 to 14 per cent., calculated on the dry extract. Gentiopierin crystallises in two forms: anhydrous, $C_{10}H_{20}O_5$ and hydrated $C_{10}H_{20}O_5 \cdot \frac{1}{2}H_2O$. The former, m. pt. 191° C. is obtained from absolute alcohol or from anhydrous ethyl acetate. The latter, m. pt. 122° C., is obtained from water or hydrated ethyl acetate; after brief agitation, it becomes dehydrated and then has the m. pt. 191° C., but it does not lose weight appreciably when exposed over sulphuric acid, and is only completely dehydrated at 105° C. Gentiopierin is a lactone; its solutions are neutral to litmus, and form gentiopierinates with alkalis: the gentiopierinic acid liberated from these is gradually converted into gentiopierin. Gentiopierin forms a crystalline pentaacetyl derivative $C_{16}H_{15}O_4(C_2H_3O_2)_5$, m. pt. 139° C.; $[\alpha]_D = -164$. Hydrated gentiopierin has the $[\alpha]_D = -198.75$. Although it has less therapeutic activity than quinine, gentiopierin is found to possess distinct action as an antiperiodic.—J. O. B.

Gentiamarin. G. Tanret. Bull. Soc. Chim., 1905, 32, 1071—1073.

BESIDES crystalline gentiopierin, fresh gentian root contains notable quantities of another glucoside, *gentiamarin*, $C_{16}H_{20}O_{10}$ or $C_{16}H_{22}O_{10}$. It is obtained from the alcoholic mother liquors after crystallising out gentiopierin; these are evaporated to a syrup, the residue extracted with ether and chloroform, then dissolved in water and precipitated with a 20 per cent. solution of tannin. The precipitate formed is removed, a large excess of tannin is added to the filtrate, and the glucosidal tannate salted out, in the cold, with magnesium sulphate. The precipitate is collected, pressed, washed with saturated magnesium sulphate solution, and then extracted with 80 per cent. alcohol. The alcoholic solution is treated with excess of hydrated lead oxide, filtered, excess of lead removed with sulphuric acid, and the filtered alcoholic solution distilled *in vacuo*. The residue is gentiamarin. It is amorphous and more unpleasant in taste than gentiopierin; $[\alpha]_D$ between -80° and -90° , the higher rotation being due to a trace of gentiopierin. ($[\alpha]_D = -198.75$). When hydrolysed with sulphuric acid it gives an amorphous brown substance which is not gentiagenin, and does not give a blue colour reaction with sulphuric acid. Gentiamarin has no lactone function, and does not combine with alkalis, nor does it afford an acetyl derivative.—J. O. B.

Gentiün. G. Tanret. Bull. Soc. Chim. 1905, 33, 1073.

GENTIÜN, $C_{22}H_{28}O_{11}$, is the glucoside, sparingly soluble in water, which accompanies gentiopierin in gentian root. It accumulates in the ethyl acetate mother liquors in the preparation of the latter, and is isolated by evaporating these and precipitating the gentiün by the addition of water. It crystallises from 60 per cent. alcohol in pale yellowish, microscopic, anhydrous needles, m. pt. 274° C. It is practically insoluble in water, small amounts being dissolved in the presence of gentiopierin. It has no lactone function. It gives a blackish-green colour reaction with ferric chloride. Nitric acid dissolves it with the production of a fine green colour, which passes to orange in presence of excess of alkali. When hydrolysed in a sealed tube with dilute sulphuric acid, the reduction products give evidence of the presence of a pentose. Glucose and xylose were found to be present therein, also a yellow body, crystallising in fine needles, m. pt. 223° C., and subliming at about 195° C. This has the formula $C_4H_{10}O_5$, and is, therefore, isomeric with gentisin. It has been named gentiünin. Gentiün is remarkable as being the first glucoside known to yield xylose on hydrolysis.

—J. O. B.

Adrenalin; Physiological Activity of Substances Related to —. H. D. Dakin. Roy. Soc. Proc., B, 1905, 76, 498—503.

It appears that the catechol nucleus is essential for the

production of physiologically active substances of the type of adrenalin; the hydrogen atoms of both phenolic hydroxyl groups must be unsubstituted. When an alkyl group of low molecular weight is attached to the nitrogen atom, the substance is more active than similar derivatives of piperidine, heptylamine and benzylamine, which, in their turn, are more active than those in which an aromatic radical is attached. The reduction of ketonic bases of the type $C_6H_4(OH)_2COClR$, $OH:OH:COCH_2R = 1:2:4$, where R is a simple aliphatic radical, results in the production of bases of greatly increased physiological activity.—T. F. B.

Grindelia; Chemical Examination of —. F. B. Power and F. Tutin. Amer. Pharm. Assoc., Sept., 1905. [Advance Proof.]

THE material examined was *Grindelia robusta* or a closely allied species. The chief constituents are amorphous resins, the amount of these representing 21.6 per cent. of the official drug. These resins were extracted successively with different solvents. The petroleum extract was a greenish, sticky solid. On boiling with potassium hydroxide, ammonia was evolved. Subsequent to this treatment, hentriacontane, $C_{31}H_{64}$, and a crystalline substance melting at 166° C., probably an isomeride of phytosterol, $C_{26}H_{44}O$, were obtained, in addition to formic and higher fatty acids. The ether extract, after fusion with caustic potash, yielded fatty acids and the molecular compound of protocatechuic and parahydroxybenzoic acids, melting at 194° C. The drug contains a considerable amount of a levo-rotatory sugar, apparently *L*-glucose, also proteid substances, colouring matter, tannin, and a very small amount of an essential oil. No indication of the presence of saponin or an alkaloid was obtained.—F. S.

Sweet Orange [Citrus Aurantium]; Essential Oil of the Leaves and Stems of the —. G. Litterer. Bull. Soc. Chim. 33, 1079—1081.

THE oil distilled from the twigs and leaves of *Citrus aurantium* had the sp. gr. 0.8693; and $\alpha_D = +56.46^{20}$; $n_D = 1.472$. It contained 4 per cent. of citral, *d*-camphene, limonene and 20 per cent. of total alcohols, partly free and partly as esters. Geraniol was isolated, and *d*-linalol was probably present also.

—J. O. B.

Lemon Leaves and Twigs [Citrus Limonum]; Essential Oil of —. G. Litterer. Bull. Soc. Chim., 1905, 33, 1081.

THE oil distilled from lemon leaves and twigs had the sp. gr. 0.8824; $\alpha_D = +21.08'$; $n_D^{20} = 1.1725$. It yielded 24 per cent. of citral; no citronellal; 19.4 per cent. of total alcohols, consisting of geraniol and probably *d*-linalol; the terpenic portion contained camphene and limonene.—J. O. B.

Ginger; Essential Oil of Cochin and African —. Haensel's Report, April, 1905, 9—11.

Cochin Ginger Oil had the following characters: sp. gr. 0.8826; $\alpha_D = -4.30'$; saponification value 17; solubility in 80 per cent. alcohol, 1 part by weight in 65 parts to a not quite clear solution. The yield was only 1.5 per cent. *African ginger oil* had the sp. gr. 0.8795; $\alpha_D = -1.14$; saponification value 13.5; solubility similar to Cochin ginger oil.—J. O. B.

Fir Buds, Scotch [Pinus Sylvestris]; Essential Oil of —. Haensel's Report, April, 1905, 19—21.

By direct distillation Scotch fir buds yield 1.127 per cent. of essential oil; by cohobation and distillation the yield is increased to 1.47 per cent. The two oils, which differ in characters were collected separately.

Oil from direct distillation. Sp. gr. 0.8839 $\alpha_D = -22'$; saponification value 19.5; acetyl value 58; solubility in 80 per cent. alcohol, 1:20; colour, yellow.

Oil from cohobation. Sp. gr. 0.9388; $\alpha_D = -5.44'$; saponification value 33; acetyl value 145; solubility in 80 per cent. alcohol, 1:15 not quite clear. Colour, olive green.—J. O. B.

Phenylacetylene and Menthone; Action of Potassium Hydroxide on a Mixture of —. E. Romanow. J. russ. phys.-chem. Ges., 1905, 37, 657-659. Chem. Centr., 1905, 2, 1021.

FINELY-POWDERED fused potassium hydroxide (3.6 grms.) is added, in small portions, with frequent agitation, to a mixture of molecular proportions of menthone (10 grms.) and phenylacetylene (6.6 grms.), cooled with ice water. After allowing to stand for 12 hours at 0° C. and 5-6 days at the ordinary temperature, ether is added, a current of carbon dioxide is passed through the mixture, and the solution filtered. The ether is expelled from the filtrate, and the product is distilled *in vacuo*. A yield, amounting to 59 per cent. of the theoretical amount of the alcohol

$\text{CH}_2 < \begin{matrix} \text{CH}_2 \cdot \text{CH}(\text{C}_6\text{H}_5) \\ \text{CH}(\text{CH}_3) \cdot \text{CH}_2 \end{matrix} > \text{C} < \begin{matrix} \text{OH} \\ \text{C}(\text{C}_6\text{H}_5) \end{matrix}$, is thus obtained.

This compound boils at 196°-198° C. under 14 mm. pressure, and has the sp. gr. 1.0045 at 0°/0° C. and 0.9906 at 20°/20° C. It is a thick yellowish liquid of bitter taste and with an odour resembling that of menthone. It is decomposed into its components, menthone and phenylacetylene, on boiling with a 10 per cent. solution of potassium hydroxide.—A. S.

Phenylacetylene and Camphor; Action of Potassium Hydroxide on a Mixture of —. J. Kotkowski. J. russ. phys.-chem. Ges., 1905, 37, 659-661. Chem. Centr., 1905, 2, 1021.

A MIXTURE of molecular proportions of phenylacetylene and camphor, when treated with potassium hydroxide in a manner similar to that described in the preceding abstract, yields a tertiary alcohol:

which is a borneol, in which the hydrogen atom adjacent to the hydroxyl group is replaced by a phenylacetylene residue. The product melts at 33°-34° C. and boils at 205° C. under 14 mm. pressure. On treatment with acetyl chloride, the hydroxyl group is replaced by chlorine; the chloro derivative obtained melts at 71°-72° C., boils at 180°-185° C. under 9 mm. pressure, is easily soluble in ether and ligroin (petroleum spirit) and slightly soluble in alcohol.—A. S.

p-Phenetidine; Manufacture of a New Derivative of —. [Dipropylacet-p-phenetidine]. C. D. Abel, London. From Act.-Ges. f. Anilinfabr., Berlin. Eng. Pat. 4565, March 4, 1905.

DIPROPYLACET-p-PHENETIDINE is obtained by boiling parts of dipropylacetic acid with 3 parts of p-phenetidine or 15 hours under a reflux condenser. The product is treated with hot water, and the residue dried and recrystallized from benzene. The product thus obtained has a m. pt. of 147° C., and is sparingly soluble in hot water, and easily soluble in alcohol or benzene.—T. F. B.

Alcohols and Ethers; Manufacture of Aromatic — by the Reduction of Aromatic Esters. C. Mettler, Munich. Eng. Pat. 14,316, July 11, 1905. Under Int. Conv., July 15, 1904.

Dialkylbarbituric Acids from Cyanodialkylacetylureas; Process of Producing —. C. E. Merck. Fr. Pat. 354,452, March 20, 1905. Under Int. Conv., July 18, 1904.

IN FR. PAT. 350,600 of 1905 (this J., 1905, 750), it is stated that dialkylmalonic amides could be prepared by heating cyanodialkylacetylureas with acids. It is now found that, by heating with more concentrated acid at somewhat higher temperatures, or for a longer time, the malonic amides are converted, with loss of ammonia, into dialkylbarbituric acids.—T. F. B.

Anhydrides of Organic Acids; Preparation of —. R. Sommer. Fr. Pat. 351,742, May 29, 1905.

THE ANHYDRIDES of organic acids are produced by allowing silicon tetrafluoride to act upon the anhydrous salts of the acids. After distilling off the anhydride, silicon tetrafluoride can be regenerated from the residue by heating with sand and sulphuric acid.—F. S.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Gelatin Impregnated with Potassium Bichromate, and Rendered Insoluble by Light; Composition of —, and the Theory of the Process. A. L. Lumière and A. Seyewetz. Bull. Soc. Chim., 1905, 33, 1032-1040.

THE ACTION of light on bichromated gelatin liberates an amount of alkali, which increases with increasing exposure. Potassium hydroxide is set free in the gelatin, and forms, with the excess of bichromate, a certain amount of normal chromate, but very little chromic chromate is produced. A solution containing at least 0.1 per cent. of potassium bichromate is necessary to render gelatin insoluble. The amount of chromic oxide combining with the gelatin increases, with the concentration of the bichromate, from 0.4 to 10 per cent. of the weight of gelatin; this amount also increases with increasing exposure, but appears always to attain a limit at about 10 per cent., which is about three times the amount combined by treating gelatin with a chromium salt (see this J., 1903, 1358). It is probable that the process takes place in two stages—the first is the combination with the gelatin of about 3.5 per cent. of chromic oxide, which renders the gelatin insoluble; in the second stage, the potassium bichromate is reduced by the gelatin, and further amounts of chromic acid combine with the gelatin (according to the exposure), until sufficient potassium chromate is formed to prevent further reaction.—T. F. B.

Gelatin Rendered Insoluble by Light in Presence of Chromic Acid and Certain Metallic Bichromates; Composition of —. A. L. Lumière and A. Seyewetz. *Bull. Soc. Chim.*, 1905, **33**, 1040–1042.

THE amounts of chromic oxide contained in gelatin rendered insoluble by light in presence of chromic acid and various metallic chromates, were not widely divergent (except in the case of ferric bichromate, where it was very small), lead bichromate giving the lowest figure, and ammonium bichromate the highest. The alkali metals were not found in the gelatin, but oxides of aluminium, lead, barium, zinc and copper were present in the respective cases, in fairly large amounts, and iron in very large quantity. The amount of chromic chromate present (as indicated by the amount of chromic oxide removed by washing with ammonia) was very small in all cases.

It was further found that chromic acid and ammonium chromate (especially the latter) were more easily reduced by light in presence of gelatin than potassium bichromate, owing to no normal chromate being formed to retard the reaction. Considerably greater amounts of chromic oxide therefore combined with the gelatin (see preceding abstract).—T. F. B.

ENGLISH PATENT.

Photographic Purposes; The Coating or Preparation of Media for —. J. H. P. Gillard, Kew, and H. H. Molyneux, Hampstead. *Eng. Pat.* 1290, Jan. 23, 1905.

A MUCILAGE of the bassorin class (*i.e.*, a mucilage of bassora, tragacanth, marsh mallow root, linseed, or similar substance), combined with a solution of agar-agar or similar substance, is found to form a suitable agent for emulsifying metallic salts for photographic purposes, it being soft and plastic, though sufficiently insoluble when dry. For example, 30 grains of gum tragacanth and 120 grs. of agar-agar are boiled in 12 oz. of water until dissolved; the sensitising salt is emulsified in any suitable manner.

—T. F. B.

FRENCH PATENTS.

Photography; Process for Preparing Pigmented Albuminous or Colloidal Films for —. K. Pflanz. *Fr. Pat.* 354,715, May 27, 1905.

SEE *Eng. Pat.* 11,077 of 1905; this J., 1905, 1031.—T. F. B.

Photographic Prints; Process of Obtaining Pigment—without Transfer. E. Bühler. *Fr. Pat.* 354,722, May 27, 1905. Under Int. Conv., July 11, 1904.

IN the ordinary pigment process, pigmented bichromated gelatin is used, which necessitates double transfer. In the present process, a mixture of soap and casein is employed; this is mixed with a suitable pigment and sensitised by means of bichromate. It is stated that good results are obtained by simply exposing beneath a negative, a paper coated with such a mixture and developing in water.—T. F. B.

Photographs; Process for Obtaining — in Relief on Ceramic Objects. A. and P. Dalpayrat. *Fr. Pat.* 354,694, May 27, 1905. VIII., page 1110.

XXII.—EXPLOSIVES, MATCHES, Etc.

Glycerol; Determination of — by the Extraction Method. Dynamitfabrik Schlebusch. XXIII., page 1129.

ENGLISH PATENT.

Explosives; Manufacture of Safety —. N. Ceipek, Vienna. *Eng. Pat.* 28,256, Dec. 23, 1904.

THE invention relates to the manufacture of safety explosives of the ammonium nitrate class by mixing with the other ingredients, picric acid to an amount which falls between the inclusive limits of 7 per cent. and 10 per cent. of the mixtures. Increased safety is said to be thus obtained. (See also this J., 1901, 1240.)—G. W. McD.

FRENCH PATENT.

Explosives; Cartridge Wrappers for —. Soc. Gen. pour la Fabrication de la Dynamite. *Fr. Pat.* 350,099, Aug. 4, 1904.

THE paper used for wrapping mining cartridges is rendered unflammable by impregnating it with ammonium phosphate and boric acid, and the paraffin usually employed between the two sheets of paper is replaced by a non-flammable material. (See also this J., 1905, 1032.)

INORGANIC—QUALITATIVE.

Bromine; Detection of — in Presence of Large Excess of Iodine. H. Cormimboenf. *Ann. Chim. anal. appl.* 1905, **10**, 145–146.

Detection of Bromine in Iodides, Hydriodic Acid, &c.—Any acid present is neutralised with sodium carbonate and the salts are dissolved in water; the solution must be neutral or very slightly acid. An excess of ferric chloride solution, sp. gr. 1.420 is added, which precipitates the iodine, in a few seconds, in the form of a black powder, which is separated by filtration through glass wool. The traces of iodine remaining in the filtrate are eliminated by boiling until violet vapours cease to be disengaged. The solution is then treated with excess of caustic soda, filtered, and a crystal of potassium chlorate and some chloroform are added to the colourless filtrate; the liquid is made acid with sulphuric acid, and then excess of strong sulphuric acid added. Any bromine present will be liberated, and, on shaking, will impart a more or less intense yellow colour to the chloroform. By this method the presence of 1 mgrm. of bromine may be detected.

Detection of Bromine in Free Iodine.—The iodine is combined as ferrous iodide, by treating it with excess of reduced iron in the presence of water. After removing the uncombined iron by filtration, the filtrate is treated as above.—J. O. B.

INORGANIC—QUANTITATIVE.

Lime; Analysis of Raw and Spent —. H. L. Greville. *J. Gas Lighting*, 1905, **92**, 173–174.

A SIMPLE and rapid method for the determination of calcium oxide in lime is based on the solubility of lime in strong solutions of pure cane sugar or glycerol. The results obtained were in close agreement with those obtained by precipitation. 100 grains of the sample were slaked by adding distilled water, a solution of sugar was added, and the mixture was digested for about half an hour. The solution was diluted, and a portion titrated with standard sulphuric acid solution. The following method has been employed for the analysis of spent lime from gas works:—The lime is decomposed with hydrochloric acid, and the evolved gases passed into a cooled solution of ammonia. Excess of barium chloride solution is added to the latter, and the barium carbonate filtered off and weighed; from its weight the amount of calcium carbonate in the lime is calculated. The residue in the flask is used for the determination of the total calcium and the siliceous matter. A further portion of the sample is treated with excess of potassium permanganate solution, pure hydrochloric acid is added, and then more per-

manganate if necessary. Oxalic acid is then added and the solution heated. The liquid should contain all the sulphur as sulphate, which is determined by precipitation with barium chloride. For calculating the percentage of free lime in the sample, the ratio 74 : 48 is assumed as approximately correct for the ratio of calcium combined with sulphur acids to sulphur.—T. F. B.

Oxide [Gas-Purifying Material]; Analysis of Spent ——. H. L. Greville. *J. Gas Lighting*, 1905, 92, 37.

In the case of spent oxide which has been used for the purification of water-gas, the sulphur cannot be determined accurately by extraction with carbon bisulphide, as this solvent also dissolves heavy hydrocarbons, which are often present in considerable quantities. The following method is recommended by the author:—250 grains of the sample are dried at 100° C., and then washed on a filter with hot distilled water until free from thiocyanates (sulphocyanides) and sulphates. The material, together with the filter-paper, is then digested with a concentrated solution of sodium hydroxide for half an hour, the liquid decanted off, and the residue washed repeatedly with hot distilled water, until the total volume of solution and washings amounts to 500 c.c. The solution is then filtered, and 50 c.c. of the filtrate (=25 grains of sample) are diluted, treated with a slight excess of potassium permanganate, and hydrochloric and oxalic acids added. The solution is now boiled, and the sulphur precipitated as barium sulphate.—A. S.

Iron Oxide as a [Gas] Purifying Agent, and its Valuation as a Raw Material and in a Spent Condition. H. L. Greville. *II.*, page 1101.

Fluorspar; Quick Method for the Valuation of ——. A. W. Gregory. *Chem. News*, 1905, 92, 184—185.

The sample is dried at a temperature of 120° C. Two grms. of the sample are then ignited at a red heat until no further loss of carbon dioxide takes place. A second portion of 2 grms. is treated several times in a platinum basin with hydrofluoric acid until a constant weight is obtained. The calcium carbonate present is thus converted into calcium fluoride and any silica is driven off. The difference between the actual weight after the operation and the weight which may be deduced from the loss on ignition, is equal to the amount of silica present. A third portion of 2 grms. of the fluorspar is treated with concentrated sulphuric acid, evaporated to dryness, ignited and weighed. The increase in weight is due to the conversion of calcium carbonate and fluoride into calcium sulphate; there will also be a loss of any silica present. After allowing for the change of weight due to carbonate and silica, the remaining increase corresponds with the conversion of the fluoride into sulphate from which the percentage of calcium fluoride may be calculated.—W. P. S.

Gold Bullion; Notes on the Assay of ——. T. Kirke Rose. *J. Chem. Met. and Min. Soc. of S. Africa*, 1905, 6, 36—38.

THIS paper describes briefly the principal changes made in the assay of gold bullion at the London Mint during the past three years.

Furnace Work.—The cupels, in batches of seventy-two, six of which are check pieces, are ranged on a plumbago tray, which is lifted in and out of the furnace by means of an iron "peel" or fork with two flat prongs. The tray has a raised edge, and two grooves below for the prongs of the peel to slide in, and can be used from twenty to thirty times. The cupels are arranged on the tray by hand, and cupel tongs have been entirely discarded. The seventy-two assay pieces are charged in simultaneously by means of a nickel charging tray with sliding bottom. Deep cupels are used, the hollows being 0.75 in. in diam. and 0.3 in. deep. The muffle has been so altered that the draught through it has been made independent of the furnace draught, and the first row of assays is 7 in. from the

front of the furnace. Air is admitted only near the top of the mouth of the muffle, and the assays are protected from the direct draught by a fire-brick 2 in. high. The charges with 4 grms. of lead in each assay piece, are worked off in ten or fifteen minutes.

Parting Alloy.—For many years 1.375 grms. of silver have been added to 0.5 gm. of gold in making up alloys for parting. This ratio of 2.75 to 1 has now been reduced to 2 to 1 with improved results. Other improvements connected with the balances, weighings, and weights are described, and in the aggregate all these various small modifications have had a considerable effect on the accuracy of the assays. The number of standardised gold pots rejected and remelted at the Mint, on account of incorrect composition, has fallen from 8.55 per cent. in 1901—2 to 2.66 per cent. in 1901—5.—A. N. C.

Platinum; Determination of ——. Nordenskjöld Oesterr. Zeits. Berg- u. Hüttenw., 1905, 53, 473. *Chem.-Zeit.*, 1905, 29 [Rep.] 293.

PLATINUM is usually determined by precipitation in the metallic form by means of sodium formate, or zinc. The objections to the first method, are that the precipitate readily passes through the filter paper, and that from 12 to 24 hours are required for a determination. As regards the second method, magnesium is a better reducing agent than zinc. The details of these methods as used by the author are as follows:—(1) The solution is treated with 2 grms. of sodium formate and some ammonium acetate, diluted to 200 c.c., warmed until the evolution of carbon dioxide has begun to slacken, and then boiled for 10 to 12 hours. The black precipitate of platinum is collected and washed, a little nitric acid being added to the washing water to prevent the metal passing through the paper. Finally the filter is ignited and weighed. (2) The dilute solution is treated with a large quantity of magnesium ribbon (about 17 cm. to 1 gm. of platinum). The excess of magnesium is removed by treatment with hydrochloric acid, any magnesium oxychloride formed, also going into solution. Concordant results are stated to be given by these two methods. Iridium, ruthenium and rhodium are somewhat soluble in acids when in the precipitated state, and hence are incompletely precipitated from an acid solution. Therefore the precipitation should be made in such a way that there remains only a slight excess of magnesium. On ignition, the precipitated metals are rendered insoluble in acids, whilst the magnesium oxychloride formed, can be dissolved out. If the ignition is not continued too long, no appreciable quantities of gas are absorbed by the metals. In order to determine the platinum in the sum of the precipitated metals, the ignited powder is digested with *aqua regia*, which dissolves only the platinum (and palladium). (See also this *J.*, 1905, 1033.)—C. A. M.

Electrolytic Analysis; Use of the Rotating Anode and Mercury Cathode in ——. L. G. Kollock and E. F. Smith. *J. Amer. Chem. Soc.*, 1905, 27, 1255—1269.

RESULTS obtained with a rotating anode and with a mercury cathode respectively, have been previously described (this *J.*, 1903, 1150; 1905, 107.) In the present paper the results obtained by the method of using both a rotating anode and a mercury cathode are given. The electrolysis was effected in a tube 3.5 cm. in diameter and 7.5 cm. high, with a platinum wire sealed in at the bottom. The anode was a platinum wire, 7.5 cm. long and 1 mm. in diameter coiled into a flat spiral 1.5 cm. in diameter. It was inserted in a chuck carried by the rotator, which by means of pulleys of different sizes could be rotated at speeds ranging from 100 to 1800 revolutions per minute. The mercury used as cathode was washed with alcohol and ether and dried before weighing; about 40—50 grms. were taken for a determination. In the determination of zinc, the cathode surface was 3.5 sq. cm.; in the other experiments it was about 9 sq. cm. The results obtained are given in a series of curve diagrams and tables, from which the following are selected:—

Metal.	Weight of metal present.	Sulphuric acid present (40 drops = 1 c.c.).	Volume of electrolyte.	Current.	E.M.F.	Speed of anode.	Time.	Weight of metal found.

—A. S.

Cadmium; Electrolytic Determination of — with the aid of a Rotating Cathode. C. P. Flora. Z. anorg. Chem., 1905, 47, 1-22.

THE author has applied the use of the rotating cathode (see this J., 1903, 823; 1904, 952, 1113) to the determination of cadmium by some of the electrolytic methods which have been proposed at different times. It was found that the cadmium in cadmium sulphate could be deposited satisfactorily in this way from solutions containing sulphuric acid, sodium acetate and acetic acid, or potassium cyanide. The results were not quite so good with solutions containing urea, formaldehyde or acetaldehyde, pyrophosphates, phosphates, tartaric acid, or formic acid. In the case of cadmium chloride, the best results were obtained with solutions containing sulphuric acid, potassium cyanide or pyrophosphates. The cadmium in cadmium nitrate could be deposited satisfactorily only from solutions containing potassium cyanide. Cadmium could not be deposited electrolytically from solutions containing 1 per cent. or more of free nitric acid. In the following table the conditions obtaining in some of the experiments in which satisfactory results were obtained are given.—

be decolorised by the addition of a little water and finely powdered sodium thiosulphate. This method depends upon the formation of formaldehyde by oxidation of methyl alcohol and its subsequent reaction with morphine-sulphuric acid.—F. S.

Methyl Alcohol; Detection of — in Liquids containing Ethyl Alcohol. [Official Test of the New U.S.P.] S. P. Sadler. Amer. J. Pharm., 1905, 77, 106-110.

THE following modification of the method of Mulliken and Scudder has been officially adopted in the latest edition of the Pharmacopœia of the United States. If the spirit to be tested be undiluted, 1 c.c. is taken, and enough distilled water added to it to make the volume up to 10 c.c. If it be already diluted, a correspondingly larger volume should be taken, so that when diluted to 10 c.c. the alcoholic strength does not exceed 10 per cent. by volume. This dilute solution is introduced into a test-tube of about 40 c.c. capacity; a copper wire spiral (made by winding 1 m. of clean No. 18 copper wire closely round a glass rod 7 m.m. thick, making a coil about 3 cm. deep, the end of the wire being formed into a handle) is then heated to redness in a soot-free flame,

ORGANIC—QUALITATIVE.

Methyl Alcohol in Spirit Preparations; Detection of —. A. Fendler and C. Mannich. Versamm. Ges. deutscher Naturforscher u. Aerzte, Sept., 1905. Chem.-Zeit., 1905, 29, 1047.

THE following method has received official recognition as a means of detecting wood spirit in preparations containing spirits of wine. Ten c.c. of the liquid to be tested are slowly distilled in a 50 c.c. flask fitted with a 75 cm. tube bent twice at right angles, serving as a condenser. When exactly 1 c.c. of distillate has collected, it is mixed with 4 c.c. of 20 per cent. sulphuric acid and 1 gm. of finely powdered potassium permanganate is added, with water-cooling and stirring. The liquid is filtered and gently boiled for half a minute, and, when cold, 1 c.c. is mixed with 5 c.c. of sulphuric acid with careful cooling. To the cooled mixture, 2.5 c.c. of a freshly prepared solution of 0.2 gm. of morphine hydrochloride in 10 c.c. of sulphuric acid are added. If the original preparation contained at least 0.5 per cent. of methyl alcohol, the mixture assumes a strong violet or reddish-violet coloration in about 20 minutes. Spirits of wine and ether can be tested without the distillation. Iodine tinctures must

plunged steadily quite to the bottom of the liquid in the test-tube, held there for a second or two, and then withdrawn. This treatment with the red-hot copper is repeated five or six times, immersing the test-tube in water to keep down the temperature of the liquid. The contents of the test-tube are then filtered into a wider tube and very gently boiled. If the odour of acetaldehyde be perceptible, the boiling is continued until this ceases to be clearly distinguished. The liquid is now cooled, and one drop of a 0.5 per cent. aqueous solution of resorcinol is added. A portion of the liquid is then cautiously floated, so that the liquids do not mix, on the surface of pure sulphuric acid, in another tube. After standing for three minutes, and then slowly rotating, a rose-red ring is developed at the junction of the two liquids if more than 2 per cent. of methyl alcohol were present.—J. O. B.

ORGANIC—QUANTITATIVE.

Glycerol; Determination of — in Soap Lyes. H. Strauss. Chem.-Zeit., 1905, 29, 1099-1100.

THE following method based on the oxidation of the glycerol by means of potassium bichromate and sulphuric

acid has been in use for several years in the State Laboratory at Darmstadt. From 3 to 4 grms. of crude glycerin, or 10 to 15 grms. of concentrated lyes (20 to 30 grms. if the lyes are very weak), are weighed out, either in the unfiltered state after thorough mixing, or after filtration from solid particles, the amount of which is determined and subsequently taken into account in calculating the proportion of glycerol. Chlorides, if present in quantity, are removed by precipitation with silver oxide, but if only traces of chlorine be present, the precipitation can be omitted and the liquid at once treated with a sufficient quantity of lead acetate to precipitate completely soap, carbonates, &c. The filtrate and washings are made up to 100 c.c. and 10 c.c. oxidised with 5 to 6 grms. of finely powdered potassium bichromate, 20 c.c. of water being added, and then, little by little, 20 c.c. of sulphuric acid (1:1). The liquid is gradually raised to the boiling point, and boiling continued for some time. The steam is condensed, and the carbon dioxide is dried and absorbed in weighed potash bulbs. The increase of weight in the potash bulbs multiplied by 0.6976, is said to give the amount of glycerol in the tenth part of the lye weighed out for the determination.—C. A. M.

Glycerol; Determination of — by the Extraction Method. Dynamitfabrik Schleichbusch. Z. angew. Chem., 1905, 18, 1656—1660.

It is found that with the extraction method of Shukoff and Sehestakoff (this J., 1905, 294) it is in general quite unnecessary in the case of an alkaline liquid to add sulphuric acid in slight excess, and then to filter the solution from any deposit and again render it slightly alkaline with potassium hydroxide. As regards the duration of the extraction, four hours is sometimes insufficient; the time should, therefore, be increased to five or six hours. It is also shown that when the extracted glycerol is dried for four or five hours at 75° to 80° C., the whole of the moisture is not expelled, and that much more reliable results are obtained by drying it for two hours at 90° to 95° C. For instance, parallel determinations of glycerol in glycerin water gave the following results:—Dried at 75° to 80° C., 16.66 per cent.; dried at 90° to 95° C., 15.68 per cent.; Hehner's bichromate method, 15.50 per cent. The results obtained when the glycerol was dried at this higher temperature were invariably slightly higher than those given by the control methods. This is to be attributed to the extraction of substances other than glycerol, which are not dissolved by the treatment with petroleum spirit. The error thus introduced does not, as a rule, exceed 0.1 to 0.2 per cent. in the case of glycerin waters or soap lyes, but is not infrequently as high as 1 per cent. in the case of crude ordynamite glycerins. In the author's opinion the method should be used as an adjunct to the existing methods (bichromate and acetic methods) rather than as a substitute for them. (See this J., 1905, 806.)—C. A. M.

Tanning Materials; Analysis of —. B. Weiss. Der Gerber, 1905, 31, 260—261, and 275—278.

THE author has thoroughly tested the method of analysis of tanning materials, which has been recently suggested by H. Wislieenus (this J. 1904, 765) and also criticises Parker-Payne's titration method (this J. 1904, 648). He compares the results with those obtained by working with chromed hide powder and finds Wislieenus' method unsatisfactory. Non-tannins, and especially the coloured non-tannins are absorbed by the porous alumina used as de-tanning agent. The action of various acids upon this material was studied, and curious results were obtained with lactic acid, more N/10 alkali being required for titrating back than corresponded to the added N/10 lactic acid.

As the Parker-Payne titration method is based upon results obtained with digallie acid only, whereas the tannin materials and extracts which the technical chemist has to deal with, contain mixtures of various unknown tannins in variable proportions, this method was not tested. The author then discusses the candle-filter method (see this J., 1905, 251). It was found that, for example, with an ordinary quebracho liquor, an

entirely clear filtrate could not be obtained in all cases when that filter was used, and, therefore, it seemed preferable to use filter-paper, with which, with some precautions clear filtrates are always attainable.

A full description of the author's method of analysis of tanning materials and extracts, by the use of chromed hide-powder as practised at present at the Vienna Research Institution is given. The powder for this purpose is prepared by digesting 1000 grms. of ordinary hide-powder (free from cellulose) with basic chromium sulphate solution made by neutralising a solution of 150 grms. of chrome alum with 24 grms. of sodium carbonate. The chromed powder is washed repeatedly and freed from wash-water by pressing through cheese-cloth till free from sulphuric acid, when it is dried and reground. 8—10 grms. of dry powder are used for an analysis, and are moistened with 30 c.c. of water and left to soak and swell up for one hour. 120 c.c. of tannin solution are then added, the whole being well shaken and left overnight. Next morning 100 c.c. are filtered off and used for the estimation of non-tannins. A correction for the quantity of added water is made by multiplying the weight of residue by 5/4. 10 grms. of the powder prepared in this way will be found sufficient for decolorising most tanning-liquors, with the exception of some highly coloured mangroves. In such cases solutions of half the prescribed strength are used. This powder is easily prepared and its absorptive properties are more constant than those of various batches of ordinary hide powder. Guided by the results of his elaborate comparative experiments, the author is of the opinion that the chromed hide-powder method is the best, and it is decided to use it at the Vienna Institute.—F. K. K.

Cyanamide; Determination of —, and Applications of the Method. R. Perotti, Gaz. chim. Ital. 1905, 35, 228—232.

THE method is based upon the reaction of cyanamide with silver nitrate according to the equation:

A measured quantity of N/100 silver nitrate solution is rendered faintly alkaline with ammonia, and the cyanamide solution is introduced gradually, the solution being warmed and frequently shaken. It is then filtered, the residue washed with faintly ammoniacal water, and the solution titrated with ammonium thiocyanate solution according to Volhard's method. The method can be applied to the determination of calcium cyanamide in the commercial product.—A. S.

Malt Analysis. Ehrlich. Allgem. Anzeiger f. Bierbrau.; through Brewers' J., 1905, 41, 623.

THE author investigated the causes of the varying results obtained in malt analyses. He finds that if the mash, after saccharification, be left to rest instead of being stirred, higher yields of extract are obtained. A similar result follows, if the mash be allowed to stand for 10 minutes before filtering, after it has been made up to 450 grms. If the mash be prepared by mixing 50 grms. of grist directly with 200 c.c. of water, a loss of extract frequently ensues owing to starch being left at the bottom of the vessel; better results are obtained by first wetting the grist well with a small quantity of water and then adding the remainder.—A. S.

Arsenic and Antimony in presence of Organic Matter; Detection and Determination of —. F. A. Norton and A. E. Koeh. J. Amer. Chem. Soc., 1905, 27, 1247—1251.

FOR the destruction of organic matter previous to the detection or determination of arsenic and antimony, the authors recommend digestion with concentrated sulphuric acid as in the Kjeldahl process. They have found that compounds of arsenic and of antimony are not volatilised on digestion with sulphuric acid, with the exception of arsenic trichloride, and this is only slightly volatile, if at all, in the presence of much organic matter. After the digestion, the arsenic or antimony can be determined by neutralising, and titrating with iodine solution, or by other known methods.—A. S.

Cocoa Preparations; Determination of Sugar and Fat in — A. Steinmann. Chem.-Zeit. 1905, 29, 1074—1075.

WELMANS' method of determining sugar and fat in cocoa preparations (Z. öfentl. Chem., 1900, 6, 304; this J., 1900, 1151 and 1901, 288) consists in treating the substance simultaneously with known volumes of water saturated with ether and of ether saturated with water. Of the ethereal solution, a definite volume is then evaporated to dryness, the residue weighed, and the result calculated out to the whole quantity of ether, allowing for the increase of volume due to the fat. The sugar in a definite volume of the aqueous solution is determined polarimetrically, and the result similarly calculated out. The specific gravities of fat and sugar are for this purpose taken by Welmans at 1.0 and 1.55 respectively.

The author finds that the changes in composition of the ether-saturated water due to rise of temperature, to solution of the sugar and to loss of ether during filtration, cause very serious errors. These errors are practically all eliminated by substituting petroleum spirit (rectified, and boiling below 60° C.) for the ether; this spirit and water are mutually insoluble, for practical purposes. The author finds the figures 0.95 and 1.60 nearer the specific gravities of cocoa-fat and sugar than Welmans' figures. The increased sugar-concentration due to the lead precipitate in clarifying for the polarimeter is almost exactly balanced by the opposite effect of the other soluble constituents of the cocoa, so that no correction need be applied for it.—J. T. D.

Amino-Acids; Determination of Nitrogen in — V. Stanek. Z. Zuckerind. in Böhmen, 1905, 30, 9—16.

THE method described is based on the decomposition of nitrosyl chloride by the amino-acids and the measurement of the nitrogen evolved. The nitrosyl chloride is prepared by adding very gradually a 40 per cent. solution of sodium nitrite to five times its volume of concentrated hydrochloric acid. The solution is stable in the cold, and can be diluted with saturated brine without decomposition. The apparatus employed for the determination is illustrated in the accompanying figure. The decomposition flask, *a*, has a capacity of 80 c.c., its stopper carries a gas-evolution tube *b* and a tube which can be connected either with the funnel *d* or with a source of carbon dioxide. The tube, *c*, leading to the absorption apparatus *g*, has a branch with tap leading to a beaker of water in which its end is submerged. Through this branch tube shown in the figure, the air can be expelled from the flask. In the lower part of the absorption cylinder the tube, *h*, dips into a flask containing caustic alkali, whilst the entrance for the gas from the tube, *c*, is trapped by mercury. The absorption cylinder, *g*, is connected by a capillary passage with the adjoining gas burette, *j*, whilst the levelling vessel, *k*, contains water. The vessel, *i*, is a second absorption apparatus containing an alkaline

solution of permanganate. For the determination, 4—5 grms. of common salt are placed in the flask, *a*, with 25 c.c. of the solution, containing 0.05—0.3 grm. of amino-acid. The air is swept out through the branch tap-tube by a stream of carbon dioxide. About 40 c.c. of the nitrosyl chloride solution are then admitted through the funnel, *d*, and the reaction is allowed to continue for 30 minutes. The gas is then expelled from *a* by introducing brine through *d* and is transferred through *g* into the burette. It is then treated in the bulb, *i*, until all the nitrous oxide has been absorbed by the permanganate. Half of the total volume of nitrogen finally measured is derived from the amino-acid. Satisfactory results are recorded for glyecol, leucine, tyrosine, glutamic acid, and aspartic acid. Betaine and certain alkaloids have no influence on the results, neither have non-nitrogenous organic substances, but ammonium salts, asparagine, urea, hydrazine, albumin, peptone, and gelatin cause a partial evolution of nitrogen.—J. F. B.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Iron Compounds; New Class of — O. Hauser. Ber., 1905, 38, 2707—2710.

AMMONIUM carbonate, as is well known, precipitates both ferric and ferrous salts; excess of the reagent, however, dissolves the precipitate in both cases. The ferric precipitate dissolves readily, and the iron can be precipitated from the solution by hydrogen sulphide or by boiling with alkalis, though not by potassium ferrocyanide; on evaporation, ferric hydroxide is gradually deposited. The ferrous precipitate is much less readily dissolved (the precipitate from 10 grms. of ferrous ammonium sulphate requires about 200 grms. of ammonium carbonate in a litre of water); the colourless solution left with a small surface exposed to the air deposits in time practically all its iron as a faintly green precipitate, seen under the microscope to consist of prismatic crystals. It appears to be a basic carbonate containing both ferrous and ferric radicals. $\text{Fe}''_2(\text{NH}_4)(\text{CO}_3)_3\text{Fe}'''0.2\text{H}_2\text{O}$. Gradual oxidation of this substance yields an olive-green powder, in which the ratio $\text{Fe}'' : \text{Fe}''' = 1 : 1$; when this stage has been reached, further oxidation proceeds much more slowly.—J. T. D.

Silver Oxide; Autocatalytic Decomposition of — G. N. Lewis. Bureau of Govt. Laboratories (Chem. Lab.), Manila, 1905, No. 30, 5—19.

IN an attempt to determine the equilibrium pressure at a given temperature in the system: $2\text{Ag}_2\text{O} = 4\text{Ag} + \text{O}_2$, silver oxide was heated at a constant temperature of 335° C. in a stout glass tube connected to a manometer. No sign of decomposition was observed for some hours, but when the reaction once began, it was found to increase in vigour, the rate of increase being greater, the higher the pressure. Quantitative experiments showed that at the beginning, the velocity of the reaction is very small, but it increases more and more rapidly to a maximum, and then falls—rapidly at first, later more slowly—until finally the reaction is complete. The decomposition thus appears to be of the character of an explosion, the velocity of which is slow enough to be measured. The acceleration of the rate of decomposition is due to the catalytic action of the metallic silver produced in the reaction; it increases with the quantity of silver present. The curves expressing the reaction-velocity at different temperatures are of the same general character, and if plotted with different units of time, so chosen that each maximum velocity is equal to unity, the curves coincide within the limits of experimental error. The temperature coefficient of the reaction-velocity was determined, and it was found that the velocity increased by about 50 per cent. for a rise of 10° C. In conclusion the author discusses the influence of the purity and the method of preparation of the silver oxide upon its decomposition, and also the nature of the catalytic action.

—A. S.

Colloidal Salts of the Alkaline-Earths. C. Neuberg. Versamm. Ges. deutscher Naturforscher u. Aerzte, Sept., 1905. Chem.-Zeit., 1905, 29, 1044—1045.

If dilute sulphuric acid be added to a solution of barium

oxide in methyl alcohol, gelatinous barium sulphate separates out. It retains its gelatinous state after drying over phosphorus pentoxide, and on ignition becomes translucent. If carbon dioxide be passed through methyl alcohol and barium hydroxide, gelatinous barium carbonate, $\text{BaCO}_3 \cdot \text{H}_2\text{O}$, is produced. It dissolves in water, but gradually decomposes. It dissolves in methyl alcohol, if carbon dioxide be passed through, forming a true colloidal solution. From an alcoholic solution of potassium hydrosulphide, a gelatinous barium hydroxy-hydrosulphide can be obtained, $\text{Ba}(\text{SH})(\text{OH})$. This forms a colloidal solution with methyl alcohol. By the evaporation of the methyl alcohol solution of barium oxide, pearly leaflets of anhydrous barium methylate $\text{Ba}(\text{OCH}_3)_2$ are produced. This forms an extremely useful saponifying reagent. The toxicity of the colloidal carbonate is only a third of that of other barium salts.—F. S.

Hydrosols; Formation of — by *Ionic Reactions*. A. Lottermoser. Versamm. Ges. deutscher Naturforscher u. Aerzte, Sept., 1905. Chem.-Zeit., 1905, 29, 1042.

ALL amorphous silver salts give rise to hydrosols by ionic reactions, provided certain limits of concentration are not exceeded. One of the reacting ions must be present in excess, and this acts as the "sol" former. If N/10 silver nitrate solution be added slowly to N/10 potassium iodide, the hydrosol of silver iodide is produced, and passes into the jelly-like condition at the end of the reaction. The same phenomena are observed if N/20 potassium iodide be added to N/20 silver nitrate. The bearing of these results on Bilitzer's theory of the formation of a dielectric layer of hydrosol is discussed.—F. S.

Fucose Phenylsazone. W. Mayer and B. Tollens. Ber., 1905, 38, 3021—3022.

WHEN fucose is treated with phenylhydrazine under Fischer's standard conditions for preparing osazones, the product obtained melts at 155° — 158° C. This product is now shown to be a mixture of the osazone and the hydrazone, owing to incomplete conversion. If the conditions of preparation be modified by doubling the proportion of water and prolonging the time of heating from 45 minutes to 75 minutes, the product consists of the pure osazone, which melts at 177.5° C. after crystallisation from alcohol. Thus it is finally established that fucose yields the same osazone as rhodose and that these two sugars form the true optical antipodes of the same methylpentose.—J. F. B.

New Books.

ENGINEERING CHEMISTRY. A Manual of Quantitative Chemical Analysis for the Use of Students, Chemists, and Engineers. By THOS. B. STILLMAN, Ph.D., Professor of Analytical Chemistry in the Stevens Institute of Technology. Third edition. Chemical Publishing Co., Easton, Pa., U.S. America. 1905. Price \$4.50.

8vo volume, containing 554 pages of subject matter, 25 pages of tables and tabulated matter, and the alphabetical index. There are 139 illustrations. The scheme of the work will be gathered from the classification of the matter, which is as follows:—Determinations of Iron in Iron wire; Alumina in Potash Alum; Copper in Copper Sulphate; Sulphur trioxide in crystallised Magnesium Sulphate; Lead in Galena, &c., &c. Analysis of Limestone. Coal and Coke Analysis. Analytical Methods for a variety of Iron Ores. Analytical scheme for Blast-Furnace Slag. Analysis of Water to determine Scale-forming Ingredients. The Sanitary Analysis of Water. Filtration of Potable Water; also of Boiler Water. Water for Locomotive Use. Feed-water Heaters. Composition of Boiler Scale. Heating Power of Coal and Coke, and its Determination. Calorimetry. Analysis of Chimney Gases with the Elliott, and Orsat-Muencke Apparatus. Gas Analysis. Heating Value of Combustible Gases.

Producer Gas. Oil Gas. Natural Gas. Calorimeters of Hartley, and of Junker. Practical Photometry. Liquid Fuel. Valuation of Coal for the Production of Gas. Determination of Sulphur in Steel and Cast Iron; of Silicon, Carbon, Phosphorus, Aluminum, Nickel and Manganese in Iron and Steel. Carbon Compounds of Iron. Chrome Steel. Classification of Steels. Analysis of Tin Plate; also of Iron Pyrites. Calculation of Blast-Furnace Slag. Chemistry of the Blast Furnace. Charging of Blast Furnaces. Graphic Method of Calculating Blast-Furnace Charges. Blast Furnace as a Power Plant. Chemical and Physical Examination of Portland Cement. Analysis of Clay, Kaolin, Fire Sand, Building Stone, &c. Physical Tests of Building Stones. Saline Efflorescence of Bricks. Asphalt. Chemical and Physical Examination of Paper. Alloys. Determination of Sulphuric Acid and free Sulphur trioxide in Fuming Nordhausen Oil of Vitriol. Sodium Cyanide as a Component of Potassium Cyanide. Soap Analysis. Technical Examination of Petroleum. Examination of Lubricating Oils. Viscosity. Flash and Fire Tests of Oils. Analysis of Lubricating Oils containing Blown Rape-seed and Blown Cotton-seed Oils. Analysis of Cylinder Deposits. Analysis of Pigments and Paints. Pyrometry. Electrical Units. Energy Equivalents.

FORTSCHRITTE DER FEERFARBENFABRIKATION UND VERWANDTER INDUSTRIEZWEIGE. An der Hand der systematisch geordneten und mit kritischen Anmerkungen versehenen deutschen Reichs-Patente. Dargestellt von Dr. P. FRIEDLAENDER, Vorstand der chemischen Abteilung des k. k. technologischen Gewerbemuseums in Wien. Siebenter Teil. 1902—1901. Julius Springer's Verlag, Berlin. 1905. Price M. 40.

QUARTO volume containing 789 pages of subject matter; 27 pages devoted to a classified register of patent numbers in Vols. I.—VII., German, French, British and American, and a further register of German Applications; 4 pages devoted to an alphabetical register of German patents. Finally there is an Alphabetical Index of the subject matter of the patents themselves.

The matter forming the subjects of the patents, the specifications of which are published in this volume, is classified as follows:—I. Intermediate products of the Coal-tar Colour Industry. II. Triphenylmethane Dyestuffs. III. Anthracene Dyestuffs. IV. Indigo. V. Acridine- and Quinoline Dyestuffs. Quinone-imide Dyestuffs. VI. Azo Dyestuffs. VII. Sulphur Dyestuffs. VIII. Dyestuffs of Various Composition and Dyeing Qualities. IX. Pharmaceutical Products. X. Odoriferous Substances for Scents, &c.

DIE ELEKTROCHEMIE DER ORGANISCHEN VERBINDUNGEN. VON DR. WALTER LÖB. Dritte erweiterte und umgearbeitete Auflage. Wilhelm Knapp's Verlag. Halle a. S. 1905. Price, M. 9.

8vo volume containing 309 pages of subject matter and the alphabetical index. There are 10 illustrations. The matter is classified as follows:—PART I. ELECTROLYTIC PROCESSES. i. Theoretical ii. Methods. iii. Electrolysis of aliphatic compounds. iv. Electrolysis of aromatic compounds. v. Electrolysis by alternating current. vi. Electrical endosmose. PART II. ELECTROTHERMIC PROCESSES AND THE SILENT ELECTRIC DISCHARGE. i. Theoretical and Methods. ii. Sparking Discharge and Flame Circuit. iii. Utilisation of the Heat of the current in solid Conductors. iv. The Silent Electric Discharge and the action of the Tesla current.

DIE ELEKTROLYSE GESCHNOLZENER SALZE. ERSTER THEIL. Verbindungen und Elemente. VON RICHARD LORENZ, Ph.D., Professor für Electrochemie und Phys. Chemie, am eidg. Polytechnikum, Zürich. Wilhelm Knapp's Verlag. Halle a. S. 1905. Price, M. 8.

8vo volume, containing 208 pages of subject matter and the indexes of authors and subject matter. The text is illustrated with nine engravings. The subject matter receives the following classification:—I. The Alkali Metals. II. The Metals of the Alkaline Earths. III. Aluminium and the Metals of the Alkaline Earths. IV. Copper and

Silver, V. Zinc, Cadmium and Mercury. VI. Germanium, Tin and Lead. VII. Arsenic, Antimony and Bismuth. VIII. Vanadium, Niobium and Tantalum. IX. Selenium and Tellurium. X. Chromium. Molybdenum, Tungsten and Uranium. XI. Manganese, Iron, Cobalt, Nickel, the Platinum Group and Gold. XII. The Metalloids.

CHEMISCH-TECHNISCHE UNTERSUCHUNGSMETHODEN. Mit Benutzung der früheren von Dr. FRIEDRICH BÖCKMANN bearbeiteten Auflagen. Herausgegeben von Dr. GEORG LANGE, Professor der tech. Chemie am Eidgenöss. Polytechnikum in Zürich. Dritter Band. 5te. Vollständig umgearbeitete und vermehrte Auflage. Julius Springer's Verlag, Berlin. Price, M. 26. Bound M. 28.

LARGE 8vo. volume, containing 1247 pages of subject matter, with 119 illustrations and 3 tables. There are indexes of authors' names and of subject matter, and an Appendix giving a series of Tables filling 44 pages.

The text is arranged and classified under the following heads, giving besides the subjects, also the names of Prof. Lunge's colleagues who have assisted in the work:— I. Mineral Oils (Prof. Dr. D. Holde). II. Oils, Fats and Waxes. The Candle Industry. Soaps and Glycerin (Dr. J. Lewkowitsch). III. Resins, Balsams and Gum-resins, also IV. Drugs and Galenical Preparations (Dr. K. Dieterich). V. Indianrubber and Vulcanised Rubber, Gutta Percha and Balata (Dr. F. Frank and Dr. E. Marckwald). VI. Ethereal Oils (Dr. E. Gildemeister). VII. Sugar Manufacture. The Raw Materials, Production, &c. (Dr. E. O. von Lippmann). VIII. Starches (Prof. Dr. C. von Eckenbrecher). IX. Spirits (Dr. E. Ebertz). X. Brandy and Liqueurs (Dr. G. Schüle). XI. Vinegar (Dr. G. Schüle). XII. Investigation of Wine (Dr. Karl Windisch). XIII. Beer (Prof. Dr. C. J. Lintner). XIV. Vegetable Tanning Agents (Prof. Dr. C. Conner). XV. Leather (Dr. J. Paessler). XVI. Paper (Prof. W. Herzberg). XVII. Ink (O. Schlüttig). XVIII. Organic Preparations (Dr. J. Messner). XIX. The Tartaric Acid Industry (Dr. H. Rasch).

XX. The Citric Acid Industry (Dr. H. Rasch). XXI. Organic Dyestuffs (Prof. Dr. R. Gnehm). XXII. Testing Textile Fibres, &c. (Dr. R. Gnehm).

MINES AND QUARRIES: GENERAL REPORT AND STATISTICS FOR 1904. PART III.—OUTPUT. [Cd. 2745.] Price 1s. 6d.

THIS return, which is prepared annually by the Home Office, contains statistics as to the quantity and value of various minerals raised in the United Kingdom. The value, at the mines and quarries, of the mineral output of the United Kingdom in 1904, as shown in the detailed table on page 153, was 97,477,639*l.*, as compared with 101,808,404*l.* in 1903.

IRON AND STEEL, 1904. STATISTICAL TABLES. 296. Price 3d.

THIS memorandum, which has been drawn up in the Commercial, Labour and Statistical Department of the Board of Trade, is in continuation of Parliamentary Paper No. 244 of Session 1904, and deals with the production and consumption during the 14 years 1890-1903 (and where possible to 1904) of iron ore and pig iron, and the production of steel in the United Kingdom, and in the principal foreign producing countries, *viz.*, Russia, Sweden, Germany (including Luxemburg), Belgium, France, Spain, Italy, Austria-Hungary, and the United States of America.

Trade Report.

I.—GENERAL.

MINERAL PRODUCTION OF THE UNITED KINGDOM IN 1904; MINES AND QUARRIES, GENERAL REPORT AND STATISTICS, PART III., 1904.

Home Office. [Cd., 2745.]

The following table shows the quantity and value of the minerals produced in the United Kingdom in 1904, as compared with 1903:—

Mineral.	1903.		1904.	
	Quantity.	Value at the Mines and Quarries.	Quantity.	Value at the Mines and Quarries.
	Tons.	£	Tons.	£
Alum shale	3,284	410	6,532	980
Arsenical pyrites	57	57	46	151
Arsenic	902	6,533	976	5,719
Barytes	24,271	22,320	26,327	24,673
Bauxite	6,128	1,516	8,700	2,539
Bog ore	4,090	1,022	4,543	1,136
Chalk	4,469,974	192,527	4,438,728	181,057
Chert and flint	73,181	15,036	65,256	14,697
Clay and shale	16,198,021	1,767,981	15,948,915	1,772,020
Coal	230,334,469	88,227,547	232,428,272	83,851,784
Copper ore	6,428	18,655	5,276	14,172
Copper precipitate	429	3,721	189	3,780
Fluorspar	11,911	8,538	18,160	15,464
Gold ore	28,600	16,995	23,203	68,576
Gravel and sand	2,245,757	171,556	2,239,593	166,189
Gypsum	219,897	69,422	234,005	72,868
Igneous rocks	5,425,538	1,308,054	5,988,821	1,351,139
Iron ore	13,715,645*	3,229,937	13,774,282†	3,125,814
Iron pyrites	9,639	4,816	10,287	5,300

* Exclusive of 193 tons of micaceous iron ore used for paint.

† Exclusive of 322 tons of micaceous iron ore used for paint.

The total value of the minerals raised during the year amounted to 97,477,639*l.*, a decrease of 4,330,765*l.* as compared with 1903. This decrease is to be accounted for by a further fall in the average price of coal from 7*s.* 7-93*d.* per ton in 1903 to 7*s.* 2-58*d.* in 1904.

The total output of coal was the highest hitherto recorded, *viz.*, 232,428,272 tons, but the value was only 83,851,784*l.*, as against 88,227,547*l.* in 1903, when the output was 2,093,803 tons less.

The quantity of coal exported, exclusive of coke and

MINERAL PRODUCTION OF THE UNITED STATES IN 1904.

Bd. of Trade J., Oct 26, 1905.

The following statement, showing the quantity and value of some of the more important of the minerals produced in the United States in 1904, with comparative figures for the preceding year, is taken from a bulletin issued by the Geological Survey :—

		1903.		1904.	
Description of Material.		Quantity.	Value.	Quantity.	Value.

(h) Including brown coal and lignite and anthracite mined elsewhere than in Pennsylvania. Coke, 1903 : 25,274,281 short tons ; value at ovens, 66,498,664 dols. 1904 : 23,621,520 short tons ; value at ovens, 46,026,183 dols.
(i) Of 42 galls.
(j) Of 300 lbs. for natural cement and 400 lbs. for Portland cement.
(k) Of 280 lbs. net.

patent fuel and of coal shipped for the use of steamers engaged in foreign trade, was 46,255,547 tons, an increase of nearly one and a third million tons on the exports for 1903. Adding the 2,375,588 tons exported in the form of coke and patent fuel, and the 17,190,900 tons shipped for the use of British and foreign steamers engaged in foreign trade, the total quantity of coal which left the country was 55,822,035 tons. The amount of coal remaining for home consumption was 166,606,237 tons, or 3-894 tons per head of the population. 17,535,337 tons were used in the blast urnaces for the manufacture of pig-iron, as against 8,302,240 tons in the previous year.

The output of iron ore shows a further increase of 8,637 tons, but the value is less by 104,123*l.* than in 1903. The ore yielded 4,524,412 tons of iron, or more than one all of the total quantity of pig iron made in the country. 1,007,756 tons of iron ore were imported during the year, 6 per cent. of which came from Spain.

INDIA ; EXPORT TRADE OF —.

J. A. Robertson. [Cd. 2750.]

The following account deals with the exports of certain products from India during the year ended March 31, 1905 :—

The value of manganese ore represents 71-5 per cent. of the total value of all metals and manufactures thereof, other than hardware exported from India, the balance being represented by brass, copper, and iron manufactures. The rapid progress of recent years has been arrested, as the quantity exported 180,945 tons, is very slightly less than in 1903—04, though the value of 24 lakhs is 5 per cent. higher. The exports from Bombay, amounting to 36-8 per cent. of the total, are drawn from the workings in the Central Provinces, and the ore contains a higher percentage of metal than that exported from Madras, which is produced near the coast and thus escapes the heavy transit charge of a long journey by rail. Next to Russia,

India now appears to be the largest producer of manganese, which is exported to America, the United Kingdom, and the Continent for use in steel-making.

The exports of saltpetre which amounted to 348,741 cwt., value 36½ lakhs, were 11 per cent. smaller than in 1903—04, as the abnormally cold winter interfered with its manufacture. The trade is fluctuating and non-progressive, the variation during the last 20 years ranging between 321,033 cwt. in 1893—94 and 528,452 cwt. in 1896—97.

The course of the export trade in indigo in the last 10 years is indicated in the subjoined figures:—

	Quantity.	Value Rs.
	cwt.	
1895-96	187,337	5,35,45,112
1898-99	135,187	2,97,04,781
1900-01	102,491	2,13,59,808
1901-02	89,750	1,85,22,554
1902-03	65,377	1,20,56,819
1903-04	60,410	1,07,62,026
1904-05	49,232	83,46,073

The unremunerative level to which prices have been forced down by the competition of synthetic indigo has reduced the indigo plantations of Bengal to less than half the area they occupied 10 years ago, and over the whole of India the reduction in that period is 66 per cent. Planters in Bengal are strengthening their position by cultivating other crops in addition to indigo, and they can carry on a contest for supremacy with synthetic indigo for many years, but the cultivation of indigo in Madras, where the area fell by 49 per cent. in 1904, appears to be rapidly approaching extinction. The season of 1904 gave a very poor yield, the deficiency compared with the previous year being estimated in the official reports at 31 per cent. in Bengal and 45 per cent. for the whole crop. The slight rise in exports from Calcutta is due to large exports in April, 1904, from the previous year's crop.

Exports to the United Kingdom maintained the level of the previous year, and there was a better demand from the Continent, especially from Russia and France. The largest exports were as usual to Egypt (mainly cheap dry leaf indigo from Madras), but the quantity was 25·1 per cent. less than in 1903—04. Exports to Japan, which for several years had been one of the chief markets for Indian indigo, almost ceased, only 168 cwt., value Rs.27,700 being registered.

Of other dyeing and tanning materials, myrabolams are by far the most important, and the exports were above the average, but of both cutch and turmeric they were very much restricted. The figures of the trade are:—

	1903-04.		1904-05.	
	Cwt.	Rs.	Cwt.	Rs.
Cutch	112,938	19,71,896	62,562	9,71,041
Myrabolams	1,229,609	42,10,288	1,187,585	42,59,063
Turmeric	68,234	4,52,653	44,090	3,04,756

The value of all oils exported, 100½ lakhs, is 2·7 per cent. less than the exceptional trade of the previous year. The decrease was principally in vegetable oils, and owing to short supplies of copra in Madras the exports of coconut oil, valued at 48·8 lakhs in 1903-04, a sum far above all previous records, fell to 29½ lakhs, the level of 1902-03. The exports of castor oil, valued at 16·4 lakhs, fell by 21 per cent., also owing to a poor crop, and the price of all vegetable oil, other than coconut oil, decreased noticeably, the fall in the case of jinjili oil being 26 per cent. Mineral oil from Burma has made remarkable progress, the exports of nearly 4½ million galls., value 20½ lakhs, being four and a half times greater than in 1903-04. Most of it was consigned to China and the Straits Settlements where, as in India, it has to meet the strenuous competition of the amalgamated companies interested in the Eastern oil trade. Exports of paraffin wax, which is classed as an oil, increased in value by 37 per cent. to 11½ lakhs. Another product of petroleum, not included in this class, is candles, in which there is a developing

trade. The quantity exported in 1904-05 was 3,353,000 lb., value 9½ lakhs, the principal markets being China, the Straits Settlements, and Australia.

Though the tanning of hides and skins is an extensive industry throughout India, the export trade is supplied almost entirely by Madras and Bombay, the former in 1904-05 having furnished 91 per cent. of the hides and 73 per cent. of the skins, and Bombay all but an insignificant fraction of the remainder. The exports during the last three years are:—

	Hides.		Skins.	
	Cwt.	Rs.	Cwt.	Rs.
1902-03	107,879	62,84,922	149,299	2,26,96,944
1903-04	102,625	61,45,989	161,869	2,48,42,770
1904-05	123,390	82,52,052	139,214	2,02,65,121

Estimated by weight the export of raw hides was greater by 5·7 per cent. than in 1903-04, and the value increased by 17·1 per cent. Prices have risen steadily during the last four years. Skins on the other hand show a fall in price of 13·1 per cent., which may be partly due to absence of selection, for they were unusually light, and, estimated by weight, the exports were 38·4 per cent. greater than in the previous year and 36 per cent. above the previous record in 1901-02. Altogether 31½ million hides and skins, to the value of 705½ lakhs, was exported. The export figures are:—

	Hides.		Skins.	
	No.	Rs.	No.	Rs.
1902-03	8,210,524	3,01,76,046	18,820,523	2,51,93,622
1903-04	8,261,198	3,16,75,395	19,634,429	2,66,86,740
1904-05	8,722,520	3,70,87,322	22,883,726	3,34,48,263

The demand for hides was good in 1904-05 and prices advanced nearly 14 per cent., the increase in quantity being 20 per cent. and in value 34 per cent. The growing demand for export in the raw state has injuriously affected the trade in tanned skins, of which the exports declined by 14 per cent. in quantity, and 18½ per cent. in value, the lower price being partly an indication of poor quality. The United Kingdom is the chief market for both tanned skins and hides, taking over 80 per cent. of the former and 90 per cent. of the latter, while most of the raw hides go to the Continent, and of the raw skins to the United States.

Prices of lac have ruled above the high level of the previous year. The exports of stick and seed lac were valued at 9½ lakhs. Of the other two principal varieties, button lac decreased in quantity from 50,500 cwt. to 34,276 cwt., a fall of 32 per cent., while shellac shows an increase from 178,497 cwt. to 193,305 cwt., a rise of 8·3 per cent. The total rise in the average price of these two is 10·3 per cent., the highest price of the year for shellac being Rs.122 per maund in April, 1904, and the lowest Rs.59 per maund in February, 1905. The total quantity is only 258 cwt. smaller, but the value of 298½ lakhs exceeds that of 1903-04 by 11·3 per cent. and of 1902-03, the next highest year, by 65 per cent. Exports to the United Kingdom were valued at 135½ lakhs, to the United States at 107½ lakhs, and to Germany at 25 lakhs.

NORWAY; NEW CUSTOMS TARIFF OF —.

The new Norwegian Customs tariff, which came into force on Aug. 8 last, is printed *in extenso* in the Board of Trade Journal for Sept. 28, pp. 590—593, Oct. 5, 21—26; Oct. 12, 71—74; Oct. 19, 113—118; Oct. 26, 165—167.

XII.—FATTY OILS, FATS, &c.

NEAT'S FOOT GREASE; U.S. CUSTOMS DECISION. Sept. 23, 1905.

Assessment of duty as an "expressed oil" under paragraph 3 of the tariff was affirmed on neat's foot grease, the crude material from which neat's foot oil is obtained. The claim of the importer that it was free of duty under paragraph 68 as a "grease or oil used only for stuffing leather" was overruled, as other uses for the article were shown by the evidence.—R. W. M.

XIIB.—RESINS, VARNISHES, Etc.ROSIN OIL; U.S. CUSTOMS DECISION. *Sept. 28, 1905.*

Rosin oil is dutiable at 25 per cent. *ad valorem*, as a "distilled oil" under paragraph 3 of the tariff.—R. W. M.

XIIC.—INDIA-RUBBER.BALATA; CRUDE —; U.S. CUSTOMS DECISION. *Sept. 28, 1905.*

The Board of General Appraisers, in overruling a claim for free entry of sheet balata as "india-rubber, crude" under paragraph 579 of the tariff, expressed the view that it was properly dutiable at 10 per cent. *ad valorem* as an "unmanufactured article unenumerated." The board held that india-rubber, gutta percha and balata are distinct articles of commerce. India-rubber and gutta percha are specifically enumerated in the free list, while balata, though equally crude, is not enumerated and hence is subject to duty.—R. W. M.

XIV.—TANNING, LEATHER, GLUE, Etc.GALALITH; U.S. CUSTOMS DECISION. *Sept. 22, 1905.*

Articles manufactured from galalith, a substance prepared from casein, were held to be dutiable at 20 per cent. *ad valorem* as "manufactured articles unenumerated," under section 6 of the tariff. The assessment of duty at 30 per cent. *ad valorem*, paragraph 449, by similitude to "manufactures of horn," was overruled.—R. W. M.

XVI.—SUGAR, STARCH, Etc.

SUGAR CROP; FRENCH —.

Times Finan. Supp., Oct. 30, 1905.

From the recently issued annual report of the French Sugar Manufacturers' Syndicate it appears that France has now 1321 sugar factories in operation, as against 1305 last season. The production of beet will amount to 7,971,300 tons, as against 4,670,000 last year. For all Europe the total crop is 45,269,190 tons, against 31,026,309 tons in 1905, an increase of 45.9 per cent. The French production of raw sugar is 970,200 tons, against 614,800 tons last year (increase of 58 per cent.); and for all Europe 6,181,050 tons (increase of 35.7 per cent.).

TRAGASOL; U.S. CUSTOMS DECISION.

Sept. 22, 1905.

Gum tragasol, a natural gum from the locust bean, used to take the place of gum tragacanth and Irish moss for carrying colour and also as a binding agent, was decided not to be free of duty as a "crude drug" under paragraph 548 of the tariff, but subject to a duty of 20 per cent. *ad valorem* under section 6, as a "manufactured article unenumerated."—R. W. M.

STARCH SUGAR [GLUCOSE] AND ITS RELATIONS TO THE FOOD STUFFS INDUSTRIES.

E. Parrow. Z. Spiritusind, 1905, 28, 396.

The German starch sugar industry was founded in 1811 at about the same time as the beet sugar industry. The production has increased nearly three times in the last 30 years, and the present annual output is estimated at 12 million cwt. This is only about 1/36th part of the production of beet sugar, so that starch sugar can hardly be regarded as a serious competitor of the latter. For certain purposes starch sugar, especially in the form of starch syrup (liquid glucose), possesses special advantages in the manufacture of confectionery, syrups, preserves and liqueurs, which advantages are not obtainable with beet sugar. Starch sugar is a cheap, wholesome foodstuff of fine quality, and has every right to exist side by side with beet sugar on equal terms. A special plea is made against restrictive legislation and taxation to the detriment of starch sugar.—J. F. B.

XVII.—BREWING, WINES, SPIRITS, Etc.

BEER; JAPANESE —.

H. Keil. Woch. f. Brau., 1905, 22, 555—557.

The manufacture of saké, the native rice-beer of Japan, is on the decline, and the production of malt and hops beer on the European system is increasing largely. This state of things is favoured by the Excise, the relative duties on saké and malt beers being in the ratio of 12:7. However, saké contains about 13.5 per cent. of alcohol, and in many respects possesses the character of a wine rather than that of a beer. The malt beer is produced in 26 breweries, but the main bulk is manufactured in four large concerns, the chief of which is the Asahi brewery at Osaka. The author has examined samples of Asahi lager beer, labelled "light" and "special light," a pasteurised and unpasteurised sample of each being submitted. The "light" beers were brewed from a wort of 13.4 per cent. strength, and the "special light" from one of 11.9 per cent. They contained 3.9 and 3.5 per cent. of alcohol respectively. The "light" beer was of very good quality and character. The "special light" beer was not quite so good; the flavour of the hop-bitters was rather too strong and dominated that of the beer.—J. F. B.

XX.—FINE CHEMICALS, Etc.

QUININE; JAVA —.

Chem. and Drug., Oct. 28, 1905.

The Bandoeng Quinine Factory's report for the year 1904 shows that 921,317 kilos. of bark have been worked during the year, containing, according to analysis, a total of 56,210.34 kilos. of cinchona alkaloids, which, after deduction of waste, yielded 54,616.66 kilos. A considerable quantity of sulphate was sold to the Dutch Indian Government at a fair price, and it was the delay in completing this transaction that delayed the report. An agreement had been come to with the Government of the Dutch Indies to deliver from 15,000 to 20,000 kilos. of quinine sulphate this year. In 1904 the Government delivered cinchona containing 27,000 kilos. of quinine, while private planters offered sufficient to keep the factory working during the year. It is hoped that the factory will be in a position this year to produce quite white, flaky quinine, and to find out the cause of the peculiar yellow tint and the defective flakiness of Java quinine. Owing to the extension of the factory, a further issue of capital has been made, to the extent of 300,000 florins (25,000/), the fourth and fifth series having now been called up.

ETHER; SULPHURIC —. U.S. CUSTOMS DECISION.

Sept. 23, 1905.

The Board of General Appraisers overruled the assessment of duty at 1 dol per lb. as an "ether, not specially provided for," under paragraph 21 of the tariff, on sulphuric ether which had been purified by distilling over metallic sodium. The claim of the importer that it was dutiable at 40 c per lb. as "sulphuric ether" was sustained, the Board recognising the fact that the article derives its name from the materials used in its manufacture.—R. W. M.

Patent List.

N.B.—In these lists, [A.] means "Application for Patent," and [C.S.] "Complete Specification Accepted."

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

II.—FUEL, GAS, AND LIGHT.

- [A.] 21,124. Shadbolt and Tully. Gas manufacture. Oct. 18.
- .. 21,135. Klönne. Coke ovens. Oct. 18.
- .. 21,369. Harding. Method of and apparatus for producing a combustible gaseous mixture.* Oct. 20.
- .. 21,405. Bowmer. Gas producers. Oct. 21.
- .. 21,417. Woodall and Duckham. Vertical retorts for the destructive distillation of coal.* Oct. 21.
- .. 21,644. Thompson (Engle and Cahill). Artificial fuel. Oct. 24.
- .. 21,715. Williams. Generation of combustible gases. Oct. 25.
- .. 21,732. Mason's Gas Power Co., Ltd., Bentley, Wright and Hollis. Gas producers. Oct. 25.
- .. 21,872. Stokes. *See under XXIII.*
- [C.S.] 23,675 (1904). Blau. Method of treating distillation gases to obtain an illuminating gas in a highly compressed form suitable for transport. Oct. 25.
- .. 27,820 (1904). Creeke. Rotary scrubbers for purifying gases. Oct. 25.
- .. 28,062 (1904). British Thomson-Houston Co. (General Electric Co.). Treating carbon and methods of producing same. Nov. 1.
- .. 241 (1905). Wagner. Apparatus for treating fuel briquettes. Oct. 25.
- .. 4043 (1905). Smith. Suction gas producers. Oct. 25.
- .. 8227 (1905). Heys (Lecde Process Co.). Apparatus for making heating or other gases. Oct. 25.
- .. 9885 (1905). Jahns. Production of producer gases. Oct. 25.
- .. 16,018 (1905). Resser. Incandescent bodies and method of making the same. Nov. 1.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

- [A.] 21,941. Walter. Process for the transformation of organic substances by partial combustion. [Ger. Appl., Oct. 27, 1904.]* Oct. 27.

- [A.] 21,954. Harrison. Treating inflammable liquids or substances to render them non-inflammable Oct. 28.

[C.S.] 29,330 (1904). Howorth (Morana Co., A.-G.). *See under XX.*

IV.—COLOURING MATTERS AND DYESTUFFS

- [A.] 21,361. Flurschein and Flurschein. Manufacture of chloro compounds of *p*-nitraniline. Oct. 20.
- .. 21,746. Johnson (Badische Anilin und Soda Fabrik.). Production of halogenated indigo white.* Oct. 25.
- .. 22,021. Abel (Act.-Ges. f. Anilinfabr.). Manufacture of a new colouring matter of the triphenyl methane series. Oct. 28.
- [C.S.] 23,193 (1904). Imray (Meister, Lucius und Brüning). *See under V.*
- .. 27,496 (1904). Abel (Act.-Ges. f. Anilinfabr.). *See under XIII A.*
- .. 27,497 (1904). Abel (Act.-Ges. f. Anilinfabr.). Manufacture of *o*-nitro derivatives and *o*-amid derivatives of certain aromatic bases. Nov. 1.
- .. 27,498 (1904). Abel (Act.-Ges. f. Anilinfabr.). Manufacture of *p*-aminophenolsulphonic acid Oct. 25.
- .. 27,499 (1904). Abel (Act.-Ges. f. Anilinfabr.). Manufacture of indophenols. Nov. 1.
- .. 7002 (1905) Imray (Meister, Lucius und Brüning). Manufacture of a bisulphite compound of a certain dyestuff. Nov. 1.
- .. 7022 (1905). Johnson (Badische Anilin und Soda Fabrik.). Manufacture of compounds of the anthracene series and of colouring matter therefrom. Oct. 25.
- .. 7910 (1905). Abel (Act.-Ges. f. Anilinfabr.). Manufacture of 5-nitro-2-amidophenol. Nov. 1.
- .. 7910a (1905). Abel (Act.-Ges. f. Anilinfabr.). Manufacture of azo-dyestuffs derived from 5-nitro-2-amidophenol. Nov. 1.
- .. 9139 (1905). Newton (Bayer und Co.). Manufacture of a new tetrazo dyestuff especially suitable for the preparation of colouring matter lakes. Oct. 25.
- .. 17,242 (1905). Johnson (Badische Anilin und Soda Fabrik.). Manufacture of colouring matter of the anthracene series. Nov. 1.

V.—PREPARING, BLEACHING, DYEING, PRINTING AND FINISHING TEXTILES, YARNS, AND FIBRES.

- [A.] 21,119. Gillies. Method of and apparatus for bleaching yarns and cloths, applicable also for the decolorisation of coloured yarns and cloths Oct. 18.
- .. 21,125. Boulton (Bond). Manufacture of waterproof fabrics.* Oct. 18.
- .. 21,311. Milan. Machines for dyeing or treating with liquids raw cotton, loose wool or silk and like material. Oct. 20.
- .. 21,437. Köther. *See under XI.*
- .. 21,505. Horteloup. Utilisation of furze cellulose and succedanea of furze for manufacturing artificial silk, celluloid, dynamite, &c. [F. Appl., Oct. 24, 1904.]* Oct. 23.
- .. 21,538. Johnson (Badische Anilin und Soda Fabrik.). Manufacture of formaldehyde sulphoxylate.* Oct. 23.
- .. 21,702. Young. Treatment of flax and hemp Oct. 25.
- .. 21,937. Lake (Leontieff). Dyeing vats.* Oct. 2

- [C.S.] 23,193 (1904). Imray (Meister, Lucius und Brüning). Manufacture of blue and violet to black dyestuffs by oxidation on the fibre. Nov. 1.
 „ 27,222 (1904). Paterson. Engraving or etching of copper rolls for calico printing. Oct. 25.
 „ 1283 (1905). Bloxam (Verein. Glanzstoff-Fabr. A.-G.). Manufacture of threads and films of cellulose. Nov. 1.
 „ 2993 (1905). Mather, Hübner and Pope. Mercerising and apparatus therefor. Oct. 25.
 „ 4593 (1905). Roberts. Carbonising wool, rags, silk and other fibres. Oct. 25.
 „ 13,952 (1905). Schmid and Schmid. Process and apparatus for ungumming silk. Nov. 1.

VI.—COLOURING WOOD, PAPER, LEATHER, ETC.

- [A.] 21,902. Pärre and Kopetz. *See under IX.*

VII.—ACIDS, ALKALIS, AND SALTS.

- [A.] 21,280. Ellis (Merck). Manufacture of a new lithium salt. Oct. 19.
 „ 21,344. Sprengel. Artificial production of diamonds. Oct. 20.
 „ 21,347. Bloxam (Gebr. Siemens und Co.). Manufacture of forms from silicon carbide.* Oct. 20.
 „ 21,538. Johnson. (Badische Anilin und Soda Fabrik). *See under V.*
 „ 21,949. Digby. *See under XI.*
 [C.S.] 27,396₁ (1904). Stead and Palmer. *See under XVII.*

VIII.—GLASS, POTTERY, AND ENAMELS.

- [C.S.] 2605 (1905). Pilkington's Tile and Pottery Co., Ltd., and Burton. Manufacture of glazed tiles. Nov. 1.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

- [A.] 21,498. Silvery. Manufacture of clay products. Oct. 23.
 „ 21,902. Pärre and Kopetz. Apparatus for impregnating and colouring wood. Oct. 27.
 [C.S.] 25,884 (1904). De la Roche. Siliceous composition. Nov. 1.
 „ 27,753 (1904). Gobbe. Rotary kilns for cement making. Oct. 25.

X.—METALLURGY.

- [A.] 17,844A. Weiss. Method of producing iron briquettes.* Oct. 18.
 „ 21,026. Wiswell. Separating metals such as gold and mercury, and means for effecting such separation. Oct. 17.
 „ 21,060. Bourcoud and Simpson. Manufacture of iron and other metals, and the utilisation of lignite and other fuel therein. Oct. 17.
 „ 21,160. Leggo. Furnaces for roasting, desulphurising, chloridising, dehydrating or drying ores and other substances.* Oct. 18.
 „ 21,206. Thomson. Hardening or treating and carbonising steel, iron, or other metal plates or articles. Oct. 19.
 „ 21,391. Swinburne. *See under XI.*
 „ 21,549. Slater. Extraction of gold and silver values from metal bearing matter. Oct. 22.
 „ 21,634. Peck. Centrifugal ore separators.* Oct. 24.
 „ 21,635. Peck. Centrifugal ore separators.* Oct. 24.
 „ 21,646. Tyars. Ore concentrating and amalgamating apparatus. Oct. 24.

- [A.] 21,650. Peck. Centrifugal ore separators.* Oct. 24.
 „ 21,663. Adams. Centrifugal ore separators.* Oct. 24.
 „ 21,721. Atkinson. Treatment of refractory ores containing iron. Oct. 25.
 „ 21,755. Fawns and Davies. Centrifugal ore and pulp washing and separating machines.* Oct. 25.
 „ 21,762. Howard. Roasting or desulphurising furnaces.* Oct. 26.
 „ 21,766. Bailey and Lovatt. Case-hardened wrought iron. Oct. 26.
 „ 21,839. Saunders and The S.O.S. Synd., Ltd. Separation of metals from their ores.* Oct. 26.
 „ 21,963. Mackenzie, and Colville and Sons, Ltd. Manufacture of steel. Oct. 28.

- [C.S.] 25,858 (1904). De Bayay. Apparatus for separating by flotation parts of the constituents of ores and other solid bodies from the remainder thereof. Oct. 25.

- „ 25,882 (1904). Jacobsen. Manufacture of bronze. Nov. 1.
 „ 28,128 (1904). Hirtz. Method of eliminating iron from solutions of nickel and cobalt. Nov. 1.
 „ 1599 (1905). Goldschmidt. Treating tinned sheet iron to facilitate the removal of the tin. Nov. 1.
 „ 3032 (1905). Claremont. Annealing copper. Nov. 1.
 „ 4052 (1905). Deister. Ore concentrators. Nov. 1.
 „ 17,534 (1905). Jenkins. Plastic composition for binding minerals. Oct. 25.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

- [A.] 20,898. Rüber. Electrolytic apparatus. [Appl. in Norway, Oct. 15, 1904.]* Oct. 16.
 „ 20,995. Cowper-Coles. Vessels for containing fused salts during electrolysis. Oct. 17.
 „ 21,391. Swinburne. Electrodeposition of zinc. Oct. 21.
 „ 21,437. Köther. Electrodes for use in the manufacture of bleaching liquor.* Oct. 21.
 „ 21,535. Berglund. Insulation for accumulators with alkaline electrolyte. [Appl. in Sweden, March 15, 1905.]* Oct. 23.
 „ 21,548. Quain and Dick. Ozone producer. Oct. 23.
 „ 21,949. Digby. Manufacture of hypochlorite solution by electrolytic methods. Oct. 28.
 [C.S.] 25,331 (1904). Hargreaves. Treating the contents of electrolytic cells. Oct. 25.
 „ 26,849 (1904). Bailey. Apparatus for electrodeposition of metals. Oct. 25.
 „ 28,129 (1904). Hirtz. Permeable diaphragms for use in electrolytic cells. Nov. 1.
 „ 29,138 (1904). Day (Empire State Dry Battery Co.). Electric dry batteries. Oct. 25.
 „ 8631 (1905). Weatherill. Dry battery. Oct. 25.
 „ 11,862 (1905). Hubbell. Galvanic battery plates. Oct. 25.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

- [C.S.] 28,442 (1904). Arledter. Utilisation of waste products in the manufacture of soaps or soap size. Nov. 1.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, ETC.

(A.)—PIGMENTS, PAINTS.

- [C.S.] 27,496 (1904). Abel (Act.-Ges. f. Anilinfabr.). Manufacture of colour lakes. Nov. 1.
 „ 28,259 (1904). Imray (Meister, Lucius und Brüning). Manufacture of yellow and orange pigment colours. Nov. 1.

- [C.S.] 9139 (1905). Newton (Bayer und Co.). *See under* IV.
 „ 15,398 (1905). Bennett and Mastin. Manufacture of pigments. Nov. 1.

(C).—INDIA-RUBBER.

- [C.S.] 19,780 (1904). Owen and Threlfall. *See under* XIV.
 „ 7129 (1905). Lawrence. Process of cleaning rubber. Oct. 25.
 „ 14,681 (1905). Alexander. Production of aqueous caoutchouc solution and regeneration of caoutchouc waste. Nov. 1.

XIV.—TANNING, LEATHER, GLUE, SIZE, ETC.

- [A.] 21,154. Lobb. Treatment of leather. Oct. 18.
 „ 21,267. Soc. Civile d'Etudes de l'Indéchirable Grimson. Manufacture of a material suitable for driving belts, &c. [Fr. Appl., July 13, 1905.]* Oct. 19.
 „ 21,443. Schowalter. Preparation for the preservation and waterproofing of leather.* Oct. 21.
 [C.S.] 19,779 (1904). Owen and Threlfall. Manufacture of leather. Oct. 25.
 „ 19,780 (1904). Owen and Threlfall. Manufacture of leather for use as a substitute for rubber, &c. Oct. 25.
 „ 26,337 (1904). Fawcus and Marr. Process and apparatus for treating animals' skins, hair, &c. Oct. 25.
 „ 29,002 (1904). Staynes. Manufacture of leather. Nov. 1.

XV.—MANURES, ETC.

- [A.] 18,990A. Gooding. *See under* XVIII.A.

XVI.—SUGAR, STARCH, GUM, ETC.

- [A.] 21,072. Dorant. Process for refining sugar.* Oct. 17.

XVII.—BREWING, WINES, SPIRITS, ETC.

- [A.] 21,376. Hunt. Treating or maturing spirits such as whiskey or brandy. Oct. 20.
 „ 21,754. Schrottky. Manufacture of fermented material.* Oct. 25.
 „ 21,928. Imray (Rach). Brewing apparatus.* Oct. 27.
 [C.S.] 22,704 (1904). Hornoff. Malt kilns. Oct. 25.
 „ 27,396 (1904). Stead and Palmer. Means and apparatus for collecting carbonic acid gas from fermentation backs or the like and sterilising same. Oct. 25.

XVIII.—FOODS; SANITATION, WATER PURIFICATION; & DISINFECTANTS.

(A).—FOODS.

- [A.] 18,990A. Gooding. Treatment of kila dirt and the like, and production of a cattle food and a manurial product.* Oct. 24.
 „ 21,946. Reis. Preparation of an alimentary substance.* Oct. 27.
 [C.S.] 11,131 (1905). Bonnicart (Exangebdi). Process of preserving eatables. Oct. 25.

(B).—SANITATION; WATER PURIFICATION.

- [A.] 21,330. Smith and Smith. Boiler compositions. Oct. 20.
 [C.S.] 3121 (1905). Adams. Filtering apparatus for sewage and other liquids. Oct. 25.

- [C.S.] 17,383 (1905). Vogelsang. Purification or filtering of sewage. Oct. 25.

(C).—DISINFECTANTS.

- [C.S.] 1530 (1905). Cooke. *See under* XX.

XIX.—PAPER, PASTEBOARD, ETC.

- [A.] 21,051. Mallandain. Manufacture of paper. Oct. 17.
 „ 21,372. West and Co., Ltd., and Webster. Means and apparatus for cleansing and sterilising pulp, &c. Oct. 20.
 „ 21,505. Horteloup. *See under* V.
 [C.S.] 29,050 (1904). Sanguinetti. Oscillating cylindrical pulp strainers. Oct. 25.
 „ 2774 (1905). Couper. Paper making apparatus. Nov. 1.
 „ 3799 (1905). Imray (Franz). Manufacture of marbled paper. Nov. 1.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

- [A.] 21,172. Jansen (Hendrikszoon). Manufacture of a solution of oxyhaemoglobin.* Oct. 18.
 „ 21,175. Abel (Act.-Ges. f. Anilinfabr.). Manufacture of amidoxy-sulphonic acids of phenyl-naphthimidazole or homologues or derivatives thereof. Oct. 18.
 „ 21,280. Ellis (Merck). *See under* VII.
 „ 21,751. Ellis (Chem. Fabr. von Heyden, A.-G.). Manufacture of double salts of antimony lactate.* Oct. 25.
 „ 21,757. Zimmermann (Chem. Fabr. auf. Actien, vorm. E. Schering). Manufacture of organic magnesium compounds and of products therefrom. Oct. 25.
 [C.S.] 28,149 (1904). Newton (Bayer und Co.). Manufacture of pyrimidine derivatives. Nov. 1.
 „ 29,330 (1904). Howorth (Morana Co., A.-G.). Process for the production of sulphuretted hydrocarbons. Nov. 1.
 „ 1530 (1905). Cooke. Mercury compounds to be used for medical disinfecting and antiseptic purposes. Nov. 1.
 „ 14,161 (1905). Traube. Process for producing dialkylmalonylurea. Oct. 25.

XXI.—EXPLOSIVES, MATCHES, ETC.

- [A.] 21,505. Horteloup. *See under* V.
 „ 21,529. Abelli. Manufacture of explosives and materials for use therein. Oct. 23.
 „ 21,779. Cocking, and Kynoch, Ltd. Smokeless powders. Oct. 26.
 [C.S.] 27,459 (1904). Lheure. Explosives. Oct. 25.
 „ 27,460 (1904). Lhenre. Explosives and the priming of the same. Oct. 25.
 „ 2875 (1905). Thompson (Saginaw Match Co.). Lucifer matches. Nov. 1.
 „ 4968 (1905). Gonsalves. Manufacture of explosives. Oct. 25.
 „ 6045 (1905). Girard. Explosives. Oct. 25.
 „ 17,741 (1905). Schneider. Explosive coherer-powder. Nov. 1.

XXII.—GENERAL ANALYTICAL CHEMISTRY.

- [A.] 21,518. Roth. Instruments for testing benzene or petroleum spirit and other liquid hydrocarbon mixtures. [Ger. Appl., Nov. 24, 1904].* Oct. 23.
 „ 21,872. Stokes. Gas calorimeter. Oct. 27.

JOURNAL OF THE Society of Chemical Industry.

A RECORD

FOR ALL INTERESTED IN CHEMICAL AND ALLIED MANUFACTURES.

ISSUED TWICE A MONTH.

No. 22.—Vol. XXIV.

NOVEMBER 30, 1905.

No. 22.—Vol. XXIV.

Subscription of Members 25/- per annum;
Entrance Fee 21/-;
Election by the Council.

Price to Non-Members 36/- per annum;
To Members 25/- per Set of extra or back numbers.
Single copies (Members and Subscribers only).
1882—1901, 2 6 each; 1902 *et seq.*, 1 9 each.

The Society of Chemical Industry.

Past Presidents:

Sir Henry E. Roscoe, B.A., D.C.L., LL.D., Ph.D., F.R.S.	1881—1882.
†Sir Frederick A. Abel, Bart., K.C.B., G.C.V.O., D.C.L., D.Sc., F.R.S.	1882—1883.
†Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, LL.D., Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Sir James Dewar, M.A., LL.D., F.R.S. ..	1887—1888.
Ludwig Mond, Ph.D., F.R.S.	1888—1889.
†Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
†E. Rider Cook	1890—1891.
J. Emerson Reynolds, M.D., F.R.S.	1891—1892.
Sir John Evans, K.C.B., D.C.L., LL.D., Sc.D., F.R.S.	1892—1893.
†E. C. C. Stanford	1893—1894.
T. E. Thorpe, C.B., LL.D., Sc.D., Ph.D., F.R.S.	1894—1895.
Thomas Tyrer	1895—1896.
†Edward Schunck, Ph.D., F.R.S.	1896—1897.
Frank Clowes, D.Sc.	1897—1898.
George Bellby	1898—1899.
C. F. Chandler, D.Sc., M.D., Ph.D., LL.D.	1899—1900.
Sir Jos. W. Swan, D.Sc., M.A., F.R.S. ..	1900—1901.
Ivan Levinstein	1901—1903.
Sir W. Ramsay, K.C.B., D.Sc., LL.D., F.R.S.	1903—1904.
Wm. H. Nichols, M.S., LL.D., D.Sc.	1904—1905.

† Deceased.

LIST OF COUNCIL, 1905—1906.

President: Dr. Edw. Divers, F.R.S.

Vice-Presidents:

Dr. L. Baekeland.	Dr. J. Lewkowitsch.
J. Carter Bell.	N. H. Martin.
Dr. Virgil Coblentz.	Max Muspratt.
Prof. W. R. E. Hodgkinson.	Dr. Wm. H. Nichols.
David Howard.	T. J. Parker.
Ivan Levinstein.	Sir Wm. Ramsay, K.C.B., F.R.S.

Ordinary Members of Council:

Dr. J. T. Dunn.	Dr. K. E. Markel.
Oscar Guttman.	B. E. R. Newlands.
H. Hemingway.	Prof. W. J. Pope, F.R.S.
Prof. W. R. Lang.	Sir Boverton Redwood.
A. R. Ling.	Walter F. Reid.
J. S. McArthur.	Dr. W. S. Squire.

Sectional Chairmen and Secretaries:

BIRMINGHAM.	
Prof. Percy F. Frankland, F.R.S. }	F. R. O'Shaughnessy.

Milton L. Hersey.	Jas. P. Murray.	

Hon. Treasurer : J. W. Bain.

Hon. Local Secretary :

Alfred Burton, 44, York Street, Toronto.

Liverpool Section.

Chairman : Eustace Carey.

Vice-Chairman : Frank Tate.

Committee :

T. Lewis Bailey.	J. T. Conroy.	C. Longuet Higgins.
J. Campbell Brown.	H. E. Davies.	E. L. Peck.
Arthur Carey.	A. Foden.	W. Collingwood
G. C. Clayton.	G. Watson Gray.	Williams.

Hon. Treasurer : W. P. Thompson.

Hon. Local Secretary :

W. R. Hardwick, 13, Batavia Buildings, Hackins Hey, Liverpool.

London Section.

Chairman : A. Gordon Salamon.

Vice-Chairman : R. J. Friswell.

Committee :

E. J. Ewan.	D. L. Howard.	Boverton Redwood.
H. G. Colman.	G. C. Jones.	Walter F. Reid.
J. N. Connah.	A. R. Ling.	F. Napier Sutton.
M. O. Forster.	B. E. R. Newlands.	Chas. Wightman.
Oscar Guttmann.	Wm. Pearce.	

Hon. Local Secretary :

Julian L. Baker, Stainesbury Holt, Kingston Road, Staines.

SESSION 1905-1906.

Monday, December 4, 1905—

W. A. Caspari, Ph.D. "Notes on Gutta Percha and Balsata"
 R. Seligman, Ph.D., and F. J. Willott. "The Determination of Zinc in Zinc-Aluminium Alloys."
 R. Seligman, Ph.D. "Distilled Water Supply for 'Works' Laboratories."
 C. J. Dickinson-Gair. "The Estimation of Naphthalene in Coal Gas."
 Bernard F. Howard, A.I.C., and F. Perry. "Salts of the Alkaloid Cinchonamine."

Manchester Section.

Chairman : G. H. Bailey.

Vice-Chairman : F. Scudder.

Committee :

J. Barnes.	B. Hart.	J. H. Lester.
J. Bürger.	W. B. Hart.	H. Porter.
W. H. Coleman.	R. S. Hutton.	T. Stenhouse.
J. Grossmann.	W. E. Kay.	W. Thomson.

Hon. Local Secretary :

Julius Hübner, Ash Villa, Cheadle Hulme, Cheshire

Newcastle Section.

Chairman : H. Louis.

Vice-Chairman : J. T. Dunn.

Committee :

P. P. Bedson.	John Pattinson.	Harry Smith.
H. S. Collins.	W. W. Proctor.	A. Spiller.
Ellwood Holmes.	W. L. Rennoldson.	J. E. Stead.
N. H. Martin.	Geo. Sisson.	C. E. Stuart.

Hon. Local Secretary and Treasurer :

F. C. Garrett, Armstrong College, Newcastle-on-Tyne.

New England Section.

Chairman : Henry Howard.

Vice-Chairman : F. E. Atteaux.

Committee :

C. R. Borland.	L. A. Olney.	Charles R. Sanger.
W. A. Gallup.	Edw. D. Pearce.	F. H. Thorp.
A. F. Hobbs.	A. Reuterdahl.	W. H. Walker.
Lawrence S. James.	F. C. Robinson.	W. J. Webber.
J. W. Loveland.		

Hon. Local Treasurer : Godfrey L. Cabot.

Hon. Local Secretary :

A. A. Claffin, Box 11-9, Boston, Mass., U.S.A.

New York Section.

Chairman : Russell W. Moore.

Vice-Chairman : Geo. C. Stone.

Committee :

C. Baskerville.	A. C. Humphreys.	Wm. H. Nichols.
Chas. F. Chandler.	E. G. Love.	T. J. Parker.
V. Coblenz.	Wm. McMurtrie.	G. A. Prochazka.
A. H. Elliott.	E. H. Miller.	W. E. Rowley.
De Lagnel Haigh.		

Hon. Treasurer : R. C. Woodcock.

Hon. Local Secretary :

H. Schweitzer, 40, Stone Street, New York, U.S.A.

Nottingham Section.

Chairman : J. M. C. Paton.

Vice-Chairman : J. T. Wood.

Committee :

L. Archbutt.	H. S. Garry.	J. O'Sullivan.
S. F. Burford.	J. Goldings.	G. J. Ward.
F. J. R. Carulla.	F. Stanley Kipping.	J. White.
R. M. Caven.	O. Quibell.	

Hon. Treasurer : S. J. Pentecost.

Hon. Local Secretary :

S. R. Trotman, King's Walk Chambers, Parliament Street, Nottingham.

Scottish Section.

Chairman : David Perry.

Vice-Chairman : J. S. Macarthur.

Committee :

R. M. Clark.	Jno. S. Ford.	Jas. Hope.
W. S. Curphey.	W. Frew.	J. Falconer King.
L. Dobbin.	R. Hamilton.	Jas. McLeod.
Thos. Ewan.	G. G. Henderson.	T. L. Patterson.
C. E. Fawcitt.	Jas. Hendrick.	D. J. Playfair.
J. Arnold Fleming.		

Hon. Secretary and Treasurer :

Thomas Gray, c/o Gourlay and Deas, 124, St. Vincent Street, Glasgow

Sydney, N.S.W., Section.

Chairman : A. Liversidge.

Committee :

W. A. Dixon.	Jas. M. Petrie.	R. Greig Smith.
V. Elliott.	A. A. Ramsay.	H. G. Smith.
G. C. Joplin.	J. A. Schofield.	T. Steel.
J. Morison.		

Hon. Local Secretary :

T. U. Walton, Colonial Sugar Co., O'Connell Street, Sydney, N.S.W.

Yorkshire Section.

Chairman : H. R. Procter.

Vice-Chairman : Thorp Whitaker.

Committee :

J. E. Bedford.	W. M. Gardner.	G. E. Scott-Smith.
F. Branson.	H. R. Hirst.	A. Smithells.
B. A. Burrell.	W. McD. Mackey.	Geo. Ward.
S. H. Davies.	F. W. Richardson.	

Hon. Local Secretary and Treasurer :

T. Fairley, 17, East Parade, Leeds.

Official Notices.

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

SIXTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY, ROME, 1906.

The Sixth International Congress of Applied Chemistry will be held in Rome in April, 1906, during Easter week. All communications should be addressed to the President, Prof. E. Paternò, Via Panisperna, 89 Rome.

Foreign and Colonial members are reminded that the subscription of 25s. for 1906, payable on January 1st next, should be sent in good time to the Hon. Treasurer (Mr. Samuel Hall) in order to ensure continuity in the receipt of the Society's Journal. Any changes of address for the new List of Members now in course of preparation should reach the General Secretary not later than January 31st, 1906.

DECENNIAL INDEX, 1896-1905.

A Collective Index to the first fourteen volumes of the Journal (1881-1895), a volume of 550 pages, was published in 1899; a few copies of this are still left, price 10s. A second volume, embracing the period 1896-1905, is now in preparation, and will be ready for printing in 1906. It will contain both a subject matter and authors' names portion, and will be a volume of about 900 pages, uniform in size with the Journal. As the number of copies to be printed will depend on the number of applications from members, the Treasurer is prepared to receive subscriptions at the rate of 10s. each copy. A form of application for this purpose will shortly be issued.

List of Members Elected.

November 23rd, 1905.

Adams, William W., Norwood, Mass., U.S.A., Leather Works Manager.
 Aleon, Armen P., 372/4 Atlantic Avenue, Boston, Mass., U.S.A., Dyestuff and Chemical Merchant.
 Barnes, F. V., 4, Annesley Grove, Nottingham, Gas Works Chemist.
 Biggar, E. B., 471, West Marion Street, Parkdale, Toronto, Canada, Editor.
 Bixby, Willard G., 194, Hester Street, New York City, U.S.A., Blacking Manufacturer.
 Brown, Hugh B., c/o James Robertson & Sons, Ltd., Thrusgrove Works, Paisley, Chemist.
 Cox, Harold N., 730, Jefferson Avenue, Brooklyn, N.Y., U.S.A., Chemist.
 Evans, Jacob V. R., Ridgway, Pa., U.S.A., Chemist.
 Felton, H. L., 126, State Street, Boston, Mass., U.S.A.
 Foregger, Dr. R. von, c/o Roessler & Hasslachner Chem. Co., 100, William Street, New York City, U.S.A., Chemist.
 Gall, J. B., Knopland, Frith Road, Belvedere, Kent, Chemist, Callender's Cable and Construction Co., Ltd.
 Glover, Nathan H., 355, River Street, Mattapan, Boston, Mass., U.S.A., Gum Manufacturer.
 Gray, W. B., Messrs. Lever Bros., Balmain, Sydney, N.S.W., Analytical Chemist.

Keller, Robt. J., c/o Geigy Aniline & Extract Co., 69, Barclay Street, New York City, U.S.A., Dyestuff and Chemical Merchant.
 Keith, Simeon C. jun., 20, Highland Avenue, Somerville, Mass., U.S.A., Chemist and Bacteriologist.
 King, Frank E., 75, Gracechurch Street, London, E.C., Analytical Chemist.
 La Pierre, Elie H., 588, Huron Avenue, Cambridge, Mass., U.S.A., Pharmacist.
 Lingley, Fredk. W., 9, Mercer Street, New York City, U.S.A., Purchasing Agent (Hard Rubber).
 Lips, Dr. Carl H., 99, Hart Street, Brooklyn, N.Y., U.S.A., Chemist.
 McCallum, A. L., c/o Dominion Iron and Steel Co., Sydney, N.S., Canada, Technical Chemist.
 McSheehy, Edward B., 64, Federal Street, Boston, Mass., U.S.A., Agent (Hemolin Co.).
 Marx, Dr. Emil, Tar Works, Beckton, E., Research Chemist.
 Mills, Wm. Henry, 45, Wall Street, New York City, U.S.A., Merchant.
 Neighorn, Albert, c/o Canada Chemical Manufacturing Co., Toronto, Canada, Agent.
 Ohliger, Willard, c/o F. Stearns & Co., Detroit, Mich., U.S.A., Chemist.
 Reed, Herbert W., 153, Milk Street, Boston, Mass., U.S.A., Dye Salesman.
 Richard, Francis C., Range Quarters, Mount Morgan, Queensland, Assayer, Mount Morgan G. M. Co.
 Riley, Louis J., 8, Newton Road, London, W., Chemist.
 Sammet, G. Victor, 73, Sheridan Street, Jamaica Plain, Mass., U.S.A., Chemist.
 Seaver, Joshua, 212, Milk Street, Boston, Mass., U.S.A., Dealer in Dyestuffs and Chemicals.
 Shoffstall, Arthur S., Woodbury, N.J., U.S.A., Chemist.
 Simons, Albert J., Elmhurst, New Barnet, Engineer.
 Sjöström, Waldemar L., 37, Farnham Street, Lawrence, Mass., U.S.A., Dyeworks Superintendent.
 Stahmann, Otto, 317, McCormick Building, Salt Lake City, Utah, U.S.A., Metallurgical Engineer.
 Strunz, Dr. C. E., 1437, Champa Street, Denver, Colo., U.S.A., Chemist.
 Swenarton, W. Hastings, Broadway Chambers, 277, Broadway, New York City, U.S.A., Patent Lawyer.
 Thorpe, Dr. J. F., Yarnaford, Heaton Mersey, Lanes., Lecturer, Manchester University.
 Torrey, Prof. H. A., Boylston Hall, Cambridge, Mass., U.S.A., Assistant Prof. of Chemistry, Harvard University.
 Walpole, G. Stanley, Lister Institute of Preventive Medicine, Chelsea Gardens, London, S.W., Research Chemist.
 Wangemann, H. P., 76-78, York Street, Westminster, S.W., Engineer and Patent Agent.
 Whetton, John, 23, Church Street, Toronto, Canada, Manager of Canadian Branch of Read Holliday and Sons, Ltd.

Changes of Address.

When notifying new addresses, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is also to be avoided as tending to create confusion. When sending subscriptions, the use of the form attached to the application helps in the verification of addresses, on which the safe delivery of the Journal depends.

Carhart, Dr. C., 1/o Nicaragua: 7 East and 7 South, Salt Lake City, Utah, U.S.A.
 Colby, Albert L., 1/o Exchange Place: 477 Central Park West, New York City, U.S.A.

- Cotton, W. H., 1/o St. Petersburg; 16 Hauptstrasse, Höchst a/Main, Germany.
- Culmann, Dr. J., 1/o Buffalo; c/o G. Siegle und Co., Stuttgart, Germany.
- Davidson, Thos. A., 1/o Glasgow; c/o Naylor Bros., Varnish Works, Southall, Middlesex.
- Dickerman, Prof. Judson C., 1/o Woburn; University of Wisconsin, Madison, Wis., U.S.A.
- Guess, H. A., 1/o Mexico; Silverton, Colo., U.S.A.
- Gurney, J. C., 1/o La Union; Fundicion de Plomo de D. Miguel Zapata, Portman, Prov. de Murcia, Spain.
- Hanson, A. M., 1/o Abbey Printworks; The Marjorie, Whalley, near Blackburn.
- Harrington, E. M., 1/o New York; c/o W. B. Lewis, 109 Broad Street, Woodbury, N.J., U.S.A.
- Heymann, Dr. Fritz; Journals (temp.) to 53, Dorotheenstrasse, Berlin, N.W.
- Mayer, And., jun., 1/o St. Mark's Avenue; 129, York Street, Brooklyn, N.Y., U.S.A.
- O'Brien, Fredk., 1/o Bedminster; 87, Dongola Road, Horfield, Bristol.
- Palmer, Fred G., 1/o Melling; Athelstan Road, Faversham, Kent.
- Pearson, Frank P., 1/o Pawtucket; 8, Richmond Street, Haverhill, Mass., U.S.A.
- Riederer, Dr. Herman S.; all communications to 251, West 95th Street, New York City, U.S.A.
- Riley, Walter A., 1/o Newmarket Road; Hazeldene, College Road, Norwich.
- Skinner, H. J.; communications to c/o A. D. Little, 93, Broad Street, Boston, Mass., U.S.A.
- Swanson, Jas. F., 1/o Govan; c/o Gildermeister and Co., Iquique, Chili.
- Toyne, Francis D., 1/o Nottingham; c/o Kelsall and Kemp, Ltd., Woodhouse Mills, Norden, near Rochdale.

Birmingham Section.

Meeting held at Birmingham on Thursday, October 26th, 1905.

PROF. P. FRANKLAND, F.R.S., IN THE CHAIR.

THE PHYSICAL AND CHEMICAL PROPERTIES OF SLAGS.

BY THOMAS TURNER, M.Sc., A.R.S.M., F.I.C.

(Professor of Metallurgy in the University of Birmingham).

When thinking of a suitable subject for the present occasion, that of the physical and chemical properties of slags suggested itself as being on the borderland of chemistry and metallurgy; as embracing products which are met with in exceptional quantities, and of which much yet remains to be understood. Few materials are produced in larger quantities than slags. According to Mr. J. M. Swank the world's production of pig iron in 1904 was 46-368 millions of tons, of which the United States supplied 38.9 per cent., Germany 21.75 per cent., and Great Britain 19.3 per cent. The slag produced per ton of pig iron varies from about 12 cwt., with charcoal furnaces and rich ores, to upwards of 30 cwt., with coke and poorer materials. Assuming the average to be 25 cwt. per ton of pig iron made, which cannot be

very far wrong, it will be seen that the iron blast furnace alone is at present responsible for the output of nearly 60,000,000 tons of slag per annum. To this must be added the slags obtained in the production of wrought iron and steel; the smelting of lead, copper, nickel, and other metals, and the products of various refining and purifying processes. The total weight of slag which is produced every year must, therefore, approach, if it does not exceed, 100,000,000 tons. Materials of such importance have, naturally, received considerable attention from scientific workers, particularly in recent years, but there are certain simple but fundamental principles which do not appear to have received the general recognition they deserve.

The usual definition of a slag is "a fusible combination of gangue and flux" which really only tells us how a slag is usually made, but does not attempt to explain what a slag is. Or, perhaps, slags may be defined as "fusible silicates obtained by the action of the flux on the impurities of the ore," though slags obtained from the basic steel process, or from the purification of gold or silver, are not silicates, and in such cases there is no ore to yield impurities. Lastly, slags are sometimes pithily defined as "smelter's refuse," but, fortunately, the profitable applications of slag in various directions in recent years renders such a definition less and less satisfactory. At present I do not remember to have read a definition of slag which is at once accurate and complete. The true constitution of slags has, however, been very clearly explained by Ledebur and by Hilgenstock (see H. F. V. Jüptner, "Siderology," pp. 289, 312), and to these views further reference will afterwards be made.

Classification of Slags.—Viewed from the standpoint of chemical composition, slags may be conveniently divided into two classes according as to whether silicic acid is, or is not, an essential constituent.

1. *Silicate Slags* are the most important commercially, and have received most attention. They include blast furnace slags from the production of iron, copper, and lead; tap cinder, acid Siemens' slag, and similar materials.

2. *Non-Silicate Slags* may be divided into two classes:

a. Those containing an acid other than silicic—such as borates, fluorides, phosphates, chlorides, sulphates, and sometimes also titanates, vanadates, &c.

b. Those consisting essentially of one or more basic oxides, such as litharge or best tap; and the mixed oxides of calcium, iron, aluminium, &c.

The present paper will deal almost exclusively with the silicate slags, as more information is available in connection with this branch of the subject, and there is great difficulty in dealing, in reasonable time, with the very varied materials included in the second group. Doubtless many of the facts and principles which apply to the former are, with suitable modifications, applicable to the latter.

The usual method of classifying silicate slags is that given in the following table:—

Oxygen Ratio. O in acid.	Older Chemical Name.	Metallurgical nomenclature.	Molecular Formula.	
			Monoxide bases.	Sesquioxide bases.
1 : 1½	½ silicate	sub-silicate	R'' ₂ SiO ₅	R''' ₂ SiO ₅
1 : 1	½ "	singulo- "	R'' ₂ SiO ₄	R''' ₂ SiO ₄
1½ : 1	¾ "	sesqui- "	R'' ₃ Si ₂ O ₁₀	R''' ₃ Si ₂ O ₁₀
2 : 1	mono- "	bi- "	R''SiO ₃	R'''SiO ₃
3 : 1	1½ "	tri- "	R'' ₃ Si ₂ O ₈	R''' ₃ Si ₂ O ₈

Physical Properties.—The more obvious physical properties of slags, such as colour, hardness, density, porosity, &c., show marked variations even in slag run from similar ores in the same furnace. The slag from iron smelting may, for example, be white, cream-coloured, olive-green, green, bright blue, brown, or black, each variation in colour corresponding to different working conditions. In fact, there is no more ready and simple method of diagnosing the internal working of a blast furnace than by observing the colour, texture, and appearance of the slag. But for our present purpose the physical properties of slags may be viewed from two aspects, namely (a), when

the slag is at or above its melting point, and (*b*) when it has solidified. At or above the melting point we have to deal with temperature of formation, fusibility, and fluidity, while at low temperatures, hardness, strength, and the power of resisting disintegration from either internal or external influence are of the first importance if slag has to be utilised for ordinary purposes, such as road metal, railway ballast, the building of walls or embankments, the formation of filter beds, the production of slag wool, or the manufacture of cast-blocks. These applications of slag are, fortunately, now of great commercial importance, but are only indirectly interesting to the metallurgist, who prefers, when possible, to concentrate his energies on his own more legitimate work. It may be stated, however, that experience shows that the slags which are most suitable for the purposes above mentioned, are such as contain in round figures 40 per cent. of silica, 40 per cent. of lime, and 20 per cent. of alumina. Those which contain under about 33 per cent. of silica, or more than about 45 per cent. of lime (or lime and magnesia), or less than 14 per cent. of alumina, are generally weak and apt to disintegrate either on exposure to the air, or if used for filter-beds. The presence of magnesia in moderate quantity is favourable to the resisting power of a slag. On the other hand, slags which are too silicious are apt to become glassy and crack, or even fly to pieces on cooling.

In the iron blast furnace it will be found that under ordinary conditions, when using coke for fuel, there is a close connection between the percentage of silica and the grade or number of the iron. Considerable variations may occur in the proportions of lime, magnesia, or alumina, without very materially affecting the product so long as the proportion of silica is correct. The temperature of working, and the proportion of sulphur in the charge, are, however, of considerable importance. Hence charcoal furnaces may make a very satisfactory product with upwards of 45 per cent. of silica in the slag, while I do not remember to have met with a case in ordinary working with coke furnaces in which a grey iron was produced when the silica in the slag exceeded 40 per cent. The range in the proportion of silica is usually a small one, varying only from about 33 to 38 per cent., though exceptionally, as in the production of basic iron, or where a very open pig is required from sulphurous materials, less than 30 per cent. of silica may be in the slag. Such a slag is, however, useless for any purpose where it is required to resist atmospheric action.

Slags from copper smelting show considerable variations in the proportion of silica. In South Wales about 30 per cent. is satisfactorily used; below this proportion the slag is too basic and usually not clean. In Montana 40 to 50 per cent. of silica is common for the clean slag from the ore furnace, and analyses of slags from the Mansfield district show 48 to 50 per cent. of silica. In the past very satisfactory results have sometimes been obtained by casting copper slags in blocks for walls, channelling, and similar purposes. Examples of this will be found in the neighbourhood of Cheadle, in North Staffordshire, and I remember that the late Mr. A. S. Bolton, of Oakmoor, was unable to tell me how long these blocks had been cast; so it is not at all unlikely that they have stood for considerably more than half a century. Cast slag blocks, probably of similar origin, have stood for many years, to my knowledge, in a wall close to the New University Buildings at Bournbrook.

Crystallisation of Slags.—It is well known that crystals of considerable size, of very definite shape, and of great beauty are sometimes met with in slags. Examples of such slags from various processes, conducted in this country, and in other parts of the world, are upon the table, and will repay careful study. Many mineralogists have contributed to the study of this branch of the subject, and slags are not unfrequently classified according to the mineralogical character of their crystals. C. Rammelsberg (*J. Iron and Steel Inst.*, 1887, Vol. 1, p. 404) divided slags into three groups which belong to the Olivine, the Augite, or the Scapolite series respectively. Probably no other writer has contributed so much to the literature of this subject as J. H. L. Vogt, whose papers have been summarised in the *Journal of the Iron and Steel Institute*

(1885, p. 694; 1886, p. 317; 1887, I., p. 405; 1889, II., p. 412; 1891, I., p. 368), and discussed in detail by Jüptner ("Siderology," pp. 136, 297, &c.). I do not, however, propose to enter, with any detail, into this branch of the subject, as its practical value to the metallurgist is very problematical. When the crystals have formed, and the mass solidified, the slag has done its work, and the metallurgist ceases to be interested in it, except in so far as its structure may indicate its probable composition when molten. It would be unsafe to assume that because certain crystalline aggregations form on cooling that, therefore, of necessity the same constituents exist combined in the same manner in the liquid mass. The size and character of the crystals depend both upon composition and rate of cooling. Slags relatively rich in oxide of iron, and also those containing from about $\frac{1}{2}$ to $\frac{3}{4}$ of their weight of silica show the greatest tendency to crystallise. Those rich in lime and alumina, like ordinary blast-furnace slag, show very little tendency to the formation of definite crystals, but are usually micro-crystalline or stony. But slags with upwards of 40 per cent. of lime sometimes give masses of crystals of a subsilicate, in the shape of very long prisms or needles, which, on exposure to the atmosphere, quickly disintegrate, and in a few hours crumble to powder. Slags which are quickly cooled in air are generally glassy, and it is not unusual with copper slags from the ore furnace to see a glassy exterior, a crystallised centre, and a micro-crystalline intermediate portion. In such a case, therefore, we have side by side a supersaturated solution, minute crystals, and definite crystallisation, depending upon the rate of cooling. Though the crystallisation of slags thus affords much interesting information, I am not aware that it is at present practically applied in our smelting works. A blast-furnace manager, for example, does not aim at the production of a slag which will crystallise in the Melilitic-Scapolite group, but one which contains a definite proportion of silica, and perhaps also of lime, alumina, and magnesia, and which will melt freely in his furnace and give the required composition of metal. The reactions and properties of slags at high temperatures are, therefore, those which are of most interest to the metallurgist, and tests conducted upon the solidified material are of interest chiefly in so far as they indicate what have been the actual conditions under which the particular high temperature reactions may have been conducted.

Properties of Slags at High Temperatures.—These include, as before mentioned, fusibility, temperature of formation, and fluidity. The question of constitution is also of great importance, but this will be dealt with separately.

The essential property of a slag is, of course, that it shall fuse at a suitable temperature and thus be capable of performing the double object of removing the impurities in the charge, and producing a metal of the desired composition. In the blast furnace, in many instances, the temperature of formation and fusibility of the slag determines the working temperature of the hearth. This is not so much the case in smelting iron ores, where there is always a considerable excess of carbon in the hearth, owing to the fact that reduction is chiefly accomplished by the action of carbon monoxide in the upper parts of the furnace, and the hearth is not merely the melting zone but also a gas producer. In this instance the rate at which carbon can be burned is probably the chief factor in determining the speed of working. But in reducing lead or copper ores the proportion of fuel is smaller, and if a high temperature is desired it can only be obtained in conjunction with a slag of high melting point, and any excess of heat will not give a higher temperature, but only lead to more rapid melting, if the furnace charge is readily fusible.

The temperature of formation of a slag is always higher than that at which the slag itself will melt if reheated after solidification. When the constituents are mixed together in fine powder it is found, as might be expected, that the formation temperature and softening point closely approximate. (Compare Boudouard, *J. Iron and Steel Inst.*, 1905, Vol. 1, pp. 339, 381.) But in practice it is obvious that where lumps of infusible materials are charged into a furnace, there must be considerable local

overheating before substances in such form can mutually combine or dissolve, and even under the most favourable conditions of ordinary practice the temperature of formation must be above the melting point of the resulting slag.

Of more importance than the temperature of formation is the question of fluidity, which is sometimes regarded as equivalent to fusibility. The melting point of a slag is very generally taken as the softening point observed when the slag is gradually heated to a high temperature. It is true that some slags are so viscid that they do not flow out of the furnace, and these have to be laboriously removed by rabbling. But such slags should be avoided whenever possible. They not merely entail the expenditure of much labour of a hot and exhausting nature, but they are usually "dirty" or rich in metal, which has afterwards to be recovered by further treatment. Such slags are also excellent non-conductors and lead to great waste of fuel in reverberatory furnaces. Hence the modern tendency is to use the blast furnace wherever possible not only for iron, but also for lead, copper, and silver ores. In the blast furnace, however, a slag which merely softens would be fatal, as it would lead to scaffolds and all kinds of troubles. Unless, then, a slag is sufficiently fluid to run freely out of the cinder hole in a blast furnace it is quite valueless. The fact that slags pass through a range of temperature during which they have very considerable viscosity renders many observations as to the temperature of softening of slags of little value for metallurgical purposes. So far as I am aware nothing has yet been done in the direction of estimating the relative fluidity or viscosity of slags at various temperatures.

Melting Points of Slags.—Jüptner, writing in 1902, pointed out that hitherto no fusing point curves have been compiled for slags, and that the existing reports on the fusing temperatures and temperatures of formation of slags are very defective. ("Siderology," p. 293.) The best known results are those of R. Akerman (*Jernkont. Ann.*, 1886, pp. 1–77), who determined the total heat of fusion of a number of slags by pouring them into a known quantity of water, while Grenet and Gredt have separately made determinations of the softening point of slags of various kinds. Various observers have also, by means of some form of optical pyrometer, recorded the temperature of slag issuing from the blast furnace, or from other sources.

By far the most important recent contribution to our knowledge of the melting points of silicates, is the paper "Experiments on the Fusibility of Blast Furnace Slags," contributed by Dr. O. Boudouard to the Iron and Steel Institute in May last. Like many other papers contributed to that Institute, Dr. Boudouard's communication was taken as read, and not discussed. In these experiments, a complete series of mixtures were made so as to give all the possible combinations of silica, alumina, and lime, so far as this was practicable in a single research. The softening points of these various single and double silicates were determined by comparison with Seger cones, and the results plotted in curves, and represented in the form of solid models. The whole forms a memoir of reference, which will doubtless be consulted by all future workers in this direction. The curves supplied allow of the ready determination of the softening point of any mixture of silica, lime, and alumina which may be desired. The only adverse criticism I feel called upon to make, is that Dr. Boudouard does not appear to have sufficiently realised the difference between fusibility and fluidity. While in the opening sentences of the paper, it is pointed out that a slag which is too viscid may form an emulsion with the metal, and lead to loss, and hence that "a high degree of fluidity is therefore indispensable in order to avoid the retention of suspended globules of metal," the first conclusion drawn from the experiments is that the softening temperatures obtained in those trials "may be regarded as practically their temperatures of fusion."

The softening point in a viscous body is dependent not only upon temperature but also upon time. A piece of pitch, for example, will flow at ordinary temperatures if left undisturbed for some months, and the softening point of a mixture of silicates must in the same manner

depend, at least in part, on the method of observation. In any case, the softening point is below the temperature at which slag and metal separate, and the former flows freely away from the latter. What the metallurgist desires to ascertain if possible is this "minimum working temperature" of the slag, if I may be permitted to introduce such an expression. At present all we know is that the minimum working temperature is higher than the softening point, usually by at least 100° C., and there is good reason to believe that the difference between the two varies considerably with the varying viscosity of the slags. Experiments which have been in progress at the University of Birmingham during the past two years, and which I propose to briefly describe, have led me to the conclusion that, though fusibility is the most characteristic and important of the physical properties of slags, yet silicate slags are also characterised by the fact that they have no melting point.

Objects of the Research.—The primary object of the research was to ascertain as far as possible what is the constitution of a typical slag, there being three suggestions worthy of consideration:—

1. That slags consist of one or more definite chemical compounds, which, though mixed together when fluid, preserve their own separate individualities, and on cooling crystallise out in the same state of combination as they exist in the fluid mass. This is apparently the view of earlier writers on the subject, and is the basis of the silicate classification of slags, and of their crystallographic nomenclature.

2. That slags consist either wholly or in great part of eutectics, and may, therefore, be expected to have definite melting points, or to show well marked arrests in their cooling curves.

3. That fluid slags are solutions of certain oxides, or other substances in fusible silicates, the constitution being usually not such as is capable of expression in any simple chemical formulae, the composition depending upon thermal and chemical equilibrium necessary to produce the required character of product.

This last view, though expressed in various ways, is the one now more generally accepted by metallurgists and is in accordance with the ideas advanced by myself in connection with the constitution of puddling cinder (S. Staff. Iron and Steel Inst., Dec., 1891. "Metallurgy of Iron," p. 299) when it was pointed out that puddling cinder may be regarded as a solution of ferrous and ferric oxides in ferrous silicate, and that at the end of the process the puddler should have "transferred the impurities from the pig iron to the cinder, and, as far as possible, saturated the cinder with impurities." We thus conceive the slag to consist of three portions (a) a fusible and relatively inactive solvent; (b) a dissolved active agent, and (c) the product of the action of this agent upon the impurity which it is desired to remove. According to this view, the composition of a slag, and its action upon a metal, is somewhat analogous to that of, say, a solution of hydrochloric acid when employed to remove scale from metallic iron. The solvent is water; the active agent is hydrochloric acid; the product of the desired reaction is ferrous chloride; while the purified metal remains. For the action to be economically and commercially successful, certain conditions of concentration and temperature are necessary, and a known excess of hydrochloric acid must remain in the solution.

Some observations of Ledebur, and also of Hilgenstock, quoted by Jüptner, put this view in clear and simple language. Thus Ledebur says "all the constituents of slags . . . appear in extremely fluctuating mutual proportions, and without reference to stoichiometric ratios. Hence it follows that a slag . . . should be regarded as a solidified solution of various chemical compounds in one another. . . . There is no reason to believe that . . . the formation of a simple mutual solution of the bodies is impossible, and that much closer combination must necessarily occur. Of course, there is no doubt but that certain combinations can occur within a solution, and therefore also within a liquid slag, though, to be sure, these combinations do not come into decided evidence until solidification is proceeding or is complete."

Hilgenstock has adopted for blast furnace slags a view almost identical with that above expressed in reference to puddling cinder, and observes, 'Blast furnace slags contain considerable quantities of "free lime" merely "dissolved" . . . In the solvent capacity for free lime alone have I been able to find an explanation of the behaviour of blast furnace slag in a number of observations.' From the title of the recently published book by Vogt on "Die Silikat Schmelzlösungen," which I have not yet had an opportunity of reading, it may be assumed that the more recent views of this well-known authority are in accordance with those above stated.

In order to throw some further light on the interesting questions which have been thus outlined, it was decided to obtain a considerable quantity of a slag in the molten condition, allow it to cool slowly, and then to ascertain by chemical, microscopic, pyrometric, and other tests how far the mass had separated into various constituents, or into portions possessing different chemical or physical properties.

Preparation of Samples.—By the kindness of the blast furnace manager, Mr. W. Moore, the slag was cast on June 6th, 1903, at Sir Alfred Hickman's furnaces, at Spring Vale, Bilston, under the superintendence of Mr. J. H. Colley, who was at that time a Bowen Research Scholar in the University of Birmingham. Mr. Colley almost immediately afterwards obtained an appointment under the Spanish Government at Trubia, and so was unable to take part in the research as was originally intended, but his place was supplied by his successor in the scholarship, Mr T. W. Picken. The furnace chosen was making an "all mine" iron from mixed native ores, and the cinder, and about 18 cwt. of slag was being made for each ton of pig iron produced. The slag was purposely retained in the furnace for some time before the ladle was filled, so as to obtain a good flush, and hence, as far as possible, to ensure uniformity. The ladle used was clean, of the tipping pattern, and taper, being 5 ft. by 5 ft. 6 in. at the top and 4 ft. 6 in. deep. The slag taken was perfectly hot and fluid, and weighed upwards of 6 tons. It was put on one side at rest, and allowed to slowly cool during four days, at the end of which the ladle was tipped and the still warm contents carefully broken and examined. A vertical section, taken through the centre of the block showed distinct differences in colour and texture, the most noticeable facts being (a) that the outer shell, which cooled most quickly, was lighter in colour, and more glassy in character; (b) that the lower central portion was grey and light blue mottled; (c) that the upper central portion, which doubtless solidified last, was of a uniformly creamy

white appearance. Samples were taken from six positions selected so as to represent the relative order of solidification, so far as this could be gathered from the shape and size of the mass. These samples were preserved in large stoppered bottles for future examination.

The accompanying diagram was prepared to represent the differences in appearance, and to show the positions from which the samples were taken. The probable order of solidification was as follows:—

Order of solidification	1	2	2	4	5	6
Reference letter	E	C	F	D	B	A

The times of solidification for samples 1 and 2 would be very near together, and 3 would not be very different, but there would probably be some hours interval between each of the others.

The samples were carefully analysed by Mr. T. W. Picken, each result being duly checked. The results are as follows:—

	Aver. composition.	Samples in order of solidification.					
		1.	2.	3.	4.	5.	6.
Silica	29.81	30.10	30.24	29.35	29.30	28.74	31.16
Alumina	19.94	19.46	19.83	21.60	20.30	21.03	18.91
Lime	40.31	40.39	39.89	40.36	39.97	39.57	41.60
Magnesia	2.95	2.97	2.94	2.91	2.79	2.82	3.28
Cal. Sulphide ..	6.92	7.04	7.11	7.32	7.83	7.71	4.56
	99.93	99.96	99.99	100.10	100.19	99.87	99.60

There were also present traces of ferrous and manganous oxides. The total lime, total sulphur, and the oxygen ratio were as follow:—

	Aver.	1.	2.	3.	4.	5.	6.
Total lime...	45.69	45.86	45.42	46.06	46.06	45.56	45.23
Sulphur	3.08	3.13	3.16	3.26	3.48	3.43	2.03
Oxygen ratio ..	0.72	0.73	0.73	0.70	0.70	0.68	0.75

The whole of the samples are such as come between the two types represented by $2\text{CaO} \cdot \text{SiO}_2$ and $3\text{CaO} \cdot \text{SiO}_2$ known respectively as the mono- and the sub-silicate.

The following tabulated statement has been prepared in order to emphasise the changes which have taken place during slow cooling. The numbers given are obtained by taking the differences between the composition of the samples and the average compositions; these differences have then been multiplied by 100 and divided by the percentage of the respective constituents in the average sample. They represent, in fact, the relative variations in 100 parts by weight of each constituent. Thus in sample No. 6 each 100 parts by weight of silica increased by 4.5 parts, while each 100 parts of alumina decreased by 5.2 parts; and similarly in other cases:—

Increases per 100 parts of each substance.

	1.	2.	3.	4.	5.	6.
Silica	1.0	1.5	—	—	—	4.5
Alumina	—	—	1.1	1.5	3.5	—
Lime	0.2	—	0.1	—	—	3.5
Magnesia	0.1	—	—	—	—	1.1
Calcium sulphide ..	1.7	2.7	5.7	13.0	11.3	—

Decreases per 100 parts of each substance.

	1.	2.	3.	4.	5.	6.
Silica	—	—	1.5	1.7	3.6	—
Alumina	2.5	0.7	—	—	—	5.2
Lime	—	1.1	—	0.9	1.9	—
Magnesia	—	0.0	0.1	0.5	0.4	—
Calcium sulphide ..	—	—	—	—	—	33.7

Top centre. Nearly cream white.
Middle. Blue mottled.
Lower centre. Coarse mottled. Blue and white.
Bottom. Passing from below upward all stages from nearly glassy to coarse grained blue mottled
Upper side. Fine close grained to blue mottled.
Lower side. From close grained to blue mottled.

An examination of the above figures indicates that there has been no important separation of silicates of lime or alumina such as might be expected if the slag were of the nature of an eutectic mixture with an excess of some other constituent. The highest variation is of quite another character, and would perhaps not be so readily anticipated. It will be observed that the last fluid portion contained only 66.3 parts of calcium sulphide for every 100 parts which were present in the original slag. This reduction of sulphur was not due to the loss by volatilisation, or to oxidation by the air, as the creamy white portion was covered with a layer of other slag, at least 6 in. in thickness. Further, it will be noticed that the loss of sulphur in one part is accompanied by a corresponding and gradual increase in sulphur in samples 3, 4, and 5. The proportion of alumina is highest in the parts which contained most sulphur, and these portions were also those which had the most marked blue colour. This appears to give some support to the suggestion that the blue colour of blast furnace slag is due to some form of oxysulphide of alumina. The total lime in sample 6 was only 0.33 per cent. lower than in sample 5, and this could be accounted for by the effect of the removal of 1.30 per cent. of sulphur, as indicated by the analyses. It would, therefore, appear that the action which took place during cooling was merely due to sulphur exchange owing to the alteration in the conditions of equilibrium as the temperature gradually fell.

It is by no means a new observation that sulphur changes in its relation to lime at low as compared with high temperatures. Thus Dr. Percy and Prof. Miller, in their "Report on Crystalline Slags" (B. A. Report, 1846, p. 351), pointed out that sulphur occurs in slags in three forms, *viz.*, free, as sulohide, and as sulphate. I have also recorded some observations on blast furnace slag, which appeared to prove that the sulphur is not always in the same state of combination, it being sometimes more readily eliminated than at others (*Journ. Iron and Steel Inst.*, 1888, Vol. I., p. 28). This part of the subject has been more fully dealt with by Jüptner von Jonstorff (*Journ. Iron and Steel Inst.*, 1902, Vol. I., p. 304), who in summarising Vogt's work, states that it has been shown that slags are capable, when in a molten condition, of dissolving sulphides and holding them in solution; but that on cooling the sulphides are the first to separate out, from which it follows that the solubility of the sulphides in slags at the ordinary temperatures of metallurgical processes is very small. Still more recently Wnest and Wolff (*ibid.*, 1905, Vol. I., p. 406), when discussing the reduction of the sulphur which is present in the coke used in the blast furnace, have stated that this sulphur is not merely carried down with the furnace charge and ultimately attacked near the hearth by the fuel and furnace gases, but that it is absorbed from the charge by the oxides of iron, after having been volatilised by the gases in the upper part of the furnace. But when the temperature exceeds 800° C., the position is reversed, and the lime then becomes the chief absorbent of sulphur. It will thus be seen that what has been observed with slowly cooled slag in reference to the separation of calcium sulphide from the longest fluid portion, is in accordance with the observations of other workers under somewhat similar conditions. Further, that apart from this migration of sulphur, there does not appear to be any indication of alteration of composition of any importance owing to the effect of the slow-cooling of a large mass of liquid slag.

In connection with the question of the removal of sulphur by magnesia, it will be observed by a comparison of Nos. 4 and 6, that the former has the highest sulphur and lowest magnesia of the series, while the latter, in which the sulphur is present in smallest proportion, has the maximum percentage of magnesia. This is in accordance with the observation that, though a self-fluxing mixture may be made from Cleveland ores, it is necessary to add lime in order to prevent the resulting pig iron from being rich in sulphur. Uehling has recently observed on this question that though magnesia is efficient as a flux, and weight for weight more effective, in proportion of 1 to 1.4, still as lime is the only flux which under ordinary conditions combines with sulphur and carries it into the

slag, lime must always be used if there is much sulphur in the blast furnace. (*Jour. Frank. Inst.* CLIX, p. 117.) Elbers has also dealt pretty fully with this subject, and concludes partly from thermo-chemical data that the influence of lime, alumina, and magnesia in causing sulphur to pass into the slag is in the order given. (This J., 1895, p. 276.)

Determination of Free Lime.—A number of attempts were made to ascertain the proportion of "free lime" in these samples of slag, but no satisfactory results were obtained. The methods employed included extraction with water; treatment with a sugar solution; and digestion with excess of acid and titrating back with alkali. It was found that the order of solubility was affected by the proportion of calcium sulphide, and that the percentage extracted was relatively small. Thus the lime obtained from a hot sugar solution was as follows:—

Samples	1.	2.	3.	4.	5.	6.
Lime per cent.	1.87	1.67	1.76	1.34	1.43	1.03

It was observed that the slag increased in weight on calcining in a muffle, and the following values were obtained on heating to redness for a few hours, and weighing from time to time till a constant result was obtained.

Samples	1.	2.	3.	4.	5.	6.
Increase in weight p. cent.	3.75	4.10	3.95	5.10	5.00	2.40

The increase of weight was doubtless due to the absorption of oxygen by the calcium sulphide. The conclusion arrived at was that in the presence of varying proportions of calcium sulphide the ordinary methods of determining "free lime" are inapplicable.

Cooling Curves of the Slags.—As it was anticipated that the cooling curves of the different samples might present interesting information, special care and trouble were taken with the preparations for, and the actual taking of, these curves. This work was done by Mr. T. W. Picken, who conducted the experiments under the direction and with the assistance of Mr. O. F. Hudson, the lecturer on metallurgy, who had already had considerable experience of such work at the Royal Mint. The ordinary gas injector furnace was used—originally salamander crucibles were employed—and the thermo-couple of the Le Chatelier type was introduced into the slag when quite fluid. But, as considerable trouble was experienced owing to one of the wires breaking off, just above the surface of the slag, before cooling was complete, the method of procedure was subsequently modified. In all the later tests the slag was melted in a carbon crucible, which was contained by an outer crucible, in order to afford the necessary protection. The thermo-couple was placed inside a thin tube of carbon, obtained by drilling a rod of hard carbon as used for arc lighting. A hot stick of similar carbon was used from time to time, as the temperature gradually rose, in order to ascertain when the slag was thoroughly fluid, at which point the thermo-couple was inserted and the crucible allowed to cool. The lid was kept on the furnace, until solidification was complete, after which the lid was removed so as to hasten the subsequent stages of cooling.

As the literature of the subject teems with figures which are stated to be the melting points of certain slags, and as these figures differ often by only a few degrees from one another, it may be at once acknowledged that we at first expected to get definite results from our observations; considerable disappointment was therefore felt as week after week passed and experiments were again and again repeated, on finding that the cooling curves were all of the same type. They showed no signs of eutectics, and no distinct line could be distinguished between the fluid, plastic, and solid state. They further showed that solidification extends over a relatively wide range of temperature, namely, from about 1345° to 1215° C., and that the plastic condition also extends over a considerable period during cooling. (See Fig. 2.)

Under the circumstances, assistance was sought from the National Physical Laboratory, and by the kindness of Dr. Glazebrook two melting point curves were supplied by Dr. Carpenter, the sample used being that marked D, or the fourth in order of solidification. This is the portion which contained the highest percentage of calcium sulphide. The slag was melted in a salamander crucible, the thermo-junction being enclosed in a carbon tube.

FIG. 2.

The lid was kept on the injector furnace while cooling from 1321° to 980°; from 980° to 690° the lid was off; while from 690° to 476° a gentle current of air was playing on the surface. The range of solidification was found to be upwards of 100° C., namely from 1253°—1140° C., and though the sample was cooled to 476°, no other evolution of heat was observed. In a second experiment the range of solidification appeared to be larger, and was not really complete till 1100°. In this case also no further evolution of heat was observed.

Assistance was also obtained from Dr. T. K. Rose, of the Royal Mint, who kindly supplied a cooling curve taken with the Roberts-Austen automatic recording pyrometer. This curve showed no marked arrest or break at any point, and Dr. Rose was of opinion that the slag was fluid at 1280° C., and that solidification commenced at 1175° C. He added, "the cooling curve appears to be a very unsatisfactory one. The slag must be very heterogeneous, and one constituent after another evidently crystallises out, the mother liquor undergoing a continuous change of composition without ever arriving at a genuine eutectic."

The results may be summarised thus:—

Hudson and Picken began	1345°	ended	1215°
Dr. Carpenter	" 1253°	"	1140°
Dr. Rose	" 1175°	"	?

When trained and competent observers obtain such results as the above, it is obvious that the material under observation has no melting point, but a wide melting range.

As the slags which have been dealt with in these experiments are somewhat basic in character, it may be well to state that Mr. W. Rosenhain has afforded evidence of a similar kind in reference to glass, in a paper read before the Optical Society of London, June 15, 1903. In this communication, Mr. Rosenhain observes that if a crucible of glass be raised to a white heat, and the thermocouple inserted and connected with a recording pyrometer, the cooling curve obtained is quite smooth, proving that no sudden solidification or crystallisation can have taken place. For sake of comparison, Mr. Rosenhain gives on the same diagram the cooling curve of copper with its well-marked freezing point, at about 1050° C., and the perfectly smooth cooling curve given by glass (see Fig. 3). Doubtless the silicate slags and the glasses form a continuous series, and what is true of the one, is, in a great measure, true of the other.

A little reflection on what is commonly known in reference to silicate slags, will confirm the statement that they have no definite melting point. The way in which

Cooling Curves of Glass & of Copper Compared (Rosenhain)

FIG. 3.

a bogie of typ cinder wells up into miniature volcanoes as it cools; the fact that slag can be blown into long filaments of wool, or drawn out in strings at the end of a rod; and the readiness with which the surface of a crucible of steel can be cleaned with a little mop of hot slag, all depend upon the existence of a considerable range of viscosity quite unlike what is usual with a metal or other pure substance. The obvious moral is that all hitherto published "melting points" of slags must be examined with caution, and comparison made only with such as have been made by similar methods. The results of Boudouard, for instance, do not become less valuable, and may be compared with each other; but they must be regarded not as giving the practical working temperatures of the various silicates in question, but as indicating the softening points as determined by a particular method.

It may be added that the samples were not suitable for microscopic examination, on account of their friable and granular structure, and though considerable time was spent on this branch of the work, only small feathery micro-crystallites were observed. There is some reason to believe, however, that there was originally some of the variety of sub-silicate of lime present which forms in long needles, and falls to pieces on exposure to the air, as the lower middle part of the block formed a certain amount of fine powder, spontaneously, when the mass was broken up, though disintegration did not afterwards proceed further. This was particularly noticed in sample 4, which was richest in calcium sulphide.

The following conclusions may be regarded as being justified from what has been before stated.

Silicate slags are heterogeneous mixtures, which, though fusible at a high temperature, have no definite melting point. They usually contain three constituents, viz.: (1) A relatively inert solvent or matrix formed of one or more fusible silicates. (2) An active agent dissolved in the solvent, and usually consisting of a metallic oxide, or a mixture of oxides. (3) The product of the action of (2) on some characteristic impurity in the charge, the proportion of which impurity entering into the metal determines its quality. At high temperatures, we thus have a system including four phases, and the results, though complicated, are such as can be determined by the application of the phase rule. Jüptner has already done something in this direction, and his further contributions to the elucidation of the subject will be received with interest.

DISCUSSION.

The CHAIRMAN congratulated the members of the Section on having had such an instructive address on the occasion of their opening meeting. Personally he had always regarded the subject of slags as dry and unattractive, but in listening to Prof. Turner's paper he had come to look upon it with interest. The subject appeared, however, to be one which must be approached with circumspection owing to the great complexity of the

problems involved. He was particularly interested to hear that these problems must be attacked from the standpoint of the Phase Rule, and that, therefore, this, like so many other fields of investigation, was destined to fall into the domain of the physical chemist. He invited other members, who had a more special knowledge of slags than he had, to discuss the paper.

Mr. A. H. HIGGINS considered that the last part of the paper was the most important, and therefore the most interesting. There were, however, some remarks made at the commencement as to which he would like to say a few words. As to the meaning of the word slag they generally looked on slag as a silicate, and he thought it might be well to confine it to that definition, leaving all other non-silicious products to be known as scoria and oxides. He had been very much interested to hear that no definite melting point was found for the slag, and thought that was what they might naturally expect from so heterogeneous a subject. Some slags had no doubt a definite melting point, but a slag was, generally speaking, like a rock which might at certain temperatures give out crystallisations. One generally spoke in a very loose way of a body crystallising out by slow cooling but slow cooling was such a wide expression that it might mean anything, and he did not think that bodies did crystallise by simple cooling, if the temperature fell below a certain point. It was necessary to keep them at a certain range of temperature for a time. That was a very important point in explaining why some slags were crystallised and others were not.

Mr. W. ROSENHAIN said that his only regret was that Professor Turner had confined himself so much to the purely metallurgical standpoint, since slags and slag-like bodies were of interest to many other chemical industries. The author had cited the results of Boudouard, but when these came to be analysed, considerable doubt as to their value must arise. In the current number of the *Iron and Steel Magazine*, the work of Boudouard had been adversely criticised by an eminent American worker, Mr. Clifford Richardson. The chief points of this criticism lay in the fact that while Boudouard's tri-axial diagram included the area representing the composition of pure Portland cement, the known melting points of these pure compounds did not at all agree with Boudouard's figures. Further, Clifford Richardson considers that the grinding of the materials used in the experimental Seger cones was not nearly fine enough. The speaker pointed out how somewhat coarse grinding, or imperfect mixing, might lead to low results when softening temperatures were to be determined; supposing the average composition of a given cone correspond to a maximum in the melting or softening point curve, then any departure from that average composition in either direction would lead to the local formation of more fusible compounds or mixtures, the whole cone softening in the form of an emulsion or suspension. The use of Seger cones for accurate temperature measurements was not advisable, since their softening temperature was admittedly a function of the time during which they were exposed to heat. Accordingly he could not attach much weight to Boudouard's results, especially as the softening temperature was necessarily so very vague. It was quite clear that a definite melting point could not be found in the ordinary way, i.e., by means of cooling curves, unless special means were employed. Two classes of cases were to be distinguished—in one class no definite melting point was found, because, although the solidification produced a crystalline aggregate, this was either a very complicated mixture with a multitude of superposed freezing points, as suggested by Dr. Rose, or because the solids formed varied continuously in composition with the temperature of formation over a very wide range of temperature; in the other class of cases there was no freezing point at all, nor even a long range of solidification, because the slag set as a viscous fluid or "glass" and did not "solidify" in the ordinary sense at all. In these latter cases, the true freezing point could be found by resorting to very slow cooling, possibly aided by "inoculation" of suitable crystals. That ordinary slags, by slow cooling, or even repeated heating and cooling, could undergo changes of

the nature of crystallisation could be well observed in the puddling cinder enclosed in ordinary wrought iron. Usually these slag enclosures appeared practically structureless under the microscope; but recently, while examining a specimen of wrought iron which had been used as a furnace tool and thus repeatedly heated and cooled, Mrs. Rosenhain had found slag enclosures which showed a marked dendritic crystallisation, illustrated in the accompanying photomicrograph, magnified 160 times;

this was undoubtedly a fine example of crystallisation in a slag at temperatures far below its melting temperature. Professor Turner's contention that what was wanted was the knowledge of the temperature required to produce a given degree of fluidity in a slag, recalled some experiments which had been published within the last two years, upon the "melting points" of certain glasses; the glasses were used in the form of rods, and drops were allowed to form and drop off on exposure to known temperatures; this recalled the German definition of a liquid as "tropbar flüssig," and apparently the temperature at which drops could form was a definite function of the substance used, and did not vary with the size of rod, &c. Perhaps some such method might lead to definite results in the case of slags.

Mr. O. F. HUDSON said that although the cooling term was a matter of very great interest, he did not see how they could expect to get any very definite or startling results from slag, because slag consisted of several substances, and a great deal depended on the separation of these constituents. Very much depended on the rate of cooling, and he commended the plan of dropping from a rod described by Mr. Rosenhain.

Mr. F. R. O'SHAUGHNESSY said he was not so much interested in the production of slag as he was in ascertaining its properties and possibilities. Prof. Turner had dealt with the subject almost entirely from the metallurgists' point of view, but the question had a considerable interest to others than metallurgists, and he belonged to that class of people. It was his duty some time ago to inspect practically the whole of the slag heaps of the Black Country, and this forced upon him the very comprehensive meaning of the word slag. The most interesting portion of Prof. Turner's paper to him was that which dealt with the composition of slag, and therefore its particular properties. The properties of slag varied greatly, according to the method of its production, and also according to its subsequent history and manipulation after leaving the furnace, and the paper would be of particular value to him as giving some information on the classification of the subject.

Mr. FRANK NOAKE, as an engineer, expressed regret that Prof. Turner had dealt so exclusively with the subject from the academic standpoint, and had told them comparatively little regarding the practical physical properties of slags. Modern high-speed railway travel was only possible on slag-packed sleepers, and he had hoped to hear the qualities essential in railway ballast slag discussed. Again, locally, a huge plant had been erected to convert slag into tar-macadam with a view to greatly improved roads for motor traffic. Would the author tell them the essential properties for "tar-mac" slag? When in America last autumn, he was greatly interested in seeing, at the Susquehanna furnaces, the molten slag run straight into water from the furnace, and thus be granulated and easily disposed of. The use of slag for bacteria-beds at sewage works was a most important application, and growing. If Prof. Turner would kindly add to their knowledge of the essentials for this use also it would be most helpful.

Mr. CHAMBERS described another method by which the slag was run from the blast furnace through a large tube on which jets of water were constantly playing, and the granulated slag fell through and was led away from the end of the tube.

Mr. HARRY SYLVESTER understood Prof. Turner to say that the use of ordinary limestone was more effective in producing a low sulphur iron than a dolomitic limestone, and under certain conditions this was true. For instance, Mr. Stead had found in smelting Cleveland iron, that when dolomite was substituted for limestone, the iron invariably changed from grey to mottled or white, the sulphur increasing in the pig iron, and the slag changing at the same time from a free flowing to a viscous material. Mr. Fernstone had, however, shown that the prejudice against magnesia was not entirely justified, but that under some conditions, a dolomitic slag removed sulphur better than an ordinary lime slag. For the advantageous substitution of magnesia for some of the lime, the slag must be comparatively low in alumina, as with a high alumina, such as the Cleveland slags contain (19 to 20 per cent.) a viscous cinder was produced, which was not an efficient desulphuriser. Allusion had been made to the composition of blast furnace slags suitable for ballast, and as a filling material for bacteria beds. Locally, slag was being exclusively used for the latter purpose, and with a proper selection—avoiding a limy slag—appeared to be a cheap, suitable material for sewage works, as it did not weather.

Mr. FRANK PLATTEN said that the paper dealt chiefly with iron slag, but he was glad that a small portion of it was devoted to slags produced in copper smelting. Last year when he was in America with the Society, he had the good fortune to visit the copper works at Detroit and Buffalo, and found them doing very excellent practice in cleaning slags produced in copper refining. The object of the metallurgist was to produce a slag low in copper with the minimum expenditure of flux, and he found that they had got a slag containing something under 0.5 per cent., with 17 per cent. lime, 40 per cent. silica, and the balance oxide of iron. When they tried the process in England, they could not obtain such good results, but probably the physical condition of the slag might have had a good deal to do with that. He had no doubt a careful study of the paper would throw some light on the subject, but if Prof. Turner could indicate the reason of the difference in results, it would probably be of great interest to many people who had experienced a similar difficulty.

Dr. ALEX. FINDLAY thanked Prof. Turner specially for the attention he had devoted to Boudouard's curves as to the melting point of slag, which had also been criticised by Richardson; and remarked that the figures of Boudouard could not be compared with those of Richardson, but were comparable only with one another. One point in the communication from Dr. T. Kirke Rose, that in cooling, a continuous curve was obtained, struck him very much, because it was very difficult to understand unless the cooling were carried too far. He supported Mr. Hiorns' view, that if cooling was too rapid,

they could not get a true cooling curve. The unfortunate point in all these questions of curves was that in the case of slags they were dealing with substances which had no true melting point.

Mr. P. L. WHITEHOUSE commended to the notice of Prof. Turner that the most satisfactory method known for determining the softening point of pitch was Kraemer and Sarnow's (this J., 1903, 291) and which might possibly help Prof. Turner to a solution of his present difficulties with regard to the determination of the softening point of slags.

Prof. TURNER, replying, said that many slags were not silicates, one of the most important of these being "basic" slag, and he was afraid it would not do to call such a slag a "scoria" as had been suggested. England was not so far behind in granulating slag as some people imagined, for a large plant had been successfully worked on the process at Bilston for some years. He agreed with Mr. Sylvester that an admixture of dolomite with lime was advantageous, but care must be taken that too much was not used. There must, under ordinary circumstances, be a considerable amount of lime to obtain iron of satisfactory quality. In reference to the crystallisation mentioned by Dr. Findlay, he understood there were several substances which crystallised gradually from the slag, and not at once. They had tried cooling at different rates; they had tried cooling quickly and cooling over a much longer period, but in no case could they obtain marked or definite points of arrest in the cooling curves. He did not see how they could apply Mr. Whitehouse's pitch test to a material held in an opaque vessel, but the subject was worthy of further careful consideration. What they required to determine was the point at which the metal would separate and flow freely from the slag, and when they determined it, they would have a thoroughly reliable metallurgical standpoint.

London Section.

Meeting held at Burlington House, on Monday, November 6th, 1905.

MR. A. GORDON SALAMON IN THE CHAIR.

EVAPORATION *IN VACUO* OF SOLUTIONS CONTAINING SOLIDS.

BY J. LEWKOWITSCH, PH.D.

Almost a century has elapsed since Howard introduced his great invention—the evaporation of sugar solutions *in vacuo*. This important improvement upon the methods practised before rapidly found favour with the sugar manufacturers, especially in this country. The advantages were obvious. The reduction of temperature effected in the concentration of sugar solutions reduced very considerably the losses which were previously encountered through the high temperature employed in concentrating the juice. Furthermore, the work could be accomplished much more rapidly than previously, as owing to the lowering of the boiling point of the liquid, the temperature-difference between heating steam and boiling liquid became much greater and, consequently, a much greater transmission of heat was obtained for a given heating surface. Not the least advantage was the employment of low pressure steam, such as exhaust steam, for the heating of the sugar pan. It is noteworthy that Howard used mechanical means for producing the vacuum, *viz.*, an air pump. The vacuum obtained by Howard was, adopting the parlance usually employed in practice, 500–550 mm., in other words, the absolute pressure was 260–220 mm. The condensed water had a temperature of 30° C. The disadvantages of Howard's apparatus—which, of course, did not militate against

its introduction at the time the invention was made—will be best considered at once, as I can thus bring out some important points, which will have to be discussed later on. The heating of Howard's apparatus was effected by means of a steam jacket. This is not an economical arrangement, as it is about the worst form of heat transmitter, partly because the air introduced with the steam lodges in the upper part of the jacket, and forms a non-conducting cushion (the remedy against this drawback, *viz.*, the usually applied air tap for intermittent blowing off of steam, can only be looked upon as a palliative) and partly because the steam is, so to speak, short-circuited, the shortest way being taken from the inlet to the outlet. The worst feature of this form of heat transmitter is, however, that the condensed water is not discharged rapidly enough. The low vapour space above the liquid in Howard's pan is bound to cause considerable losses by entrainment, solid particles in the form of a very fine mist being carried away into the condenser. Losses of this kind are not completely avoided by using a high vacuum pan with a large vapour space, such as will be considered later on. In sugar works even nowadays these losses constitute a very appreciable quantity. They have led, as I may mention *anticipando*, to the construction, during the last fifty years, of a large number of entrainment preventers. One of the most efficient of such contrivances, which has been under my personal observation for the last ten years, will be illustrated later on by some lantern slides.

The liquid itself does not circulate briskly enough, being only agitated by the steam bubbles which rise from the heating surface: frequently this is mistaken for violent boiling, whilst it actually only contributes to further loss by entrainment.

The vacuum at the outlet of the Howard pan was, as stated, about 500 mm., *i.e.*, 260 mm. in absolute pressure. To this pressure of the vapour corresponds a temperature of about 72° C. The useful heat, which might have been extracted from this steam, was lost. The loss entailed hereby became increased through the necessity of having to employ sufficient water to condense the vapours effectively. As the water ran away with a temperature of 30° C., it will be easily seen that the quantity of water used must have been considerable. Whilst about a century ago all these drawbacks were far outweighed by the advantages of the new system, they require nowadays very serious consideration.

In France, Howard's system did not find the same favour as in this country, and a retrograde step was made by abandoning the air pump and creating the vacuum by means of injection water only. Roth's apparatus (shown in a lantern slide) illustrates this principle. However, an improvement upon Howard's apparatus was made by substituting a steam coil for the steam jacket. This gives a much better transmission of heat, the air and condensation water being much more rapidly discharged. The vacuum produced here must have been still lower than in Howard's pan, hence the loss of the heat which was carried away by the water must have been greater still. Degrand attempted to evaporate a further quantity of liquor with the help of the vapours leaving the pan, these vapours being condensed in a long cooling worm over which the thin liquor was allowed to trickle, whilst an ascending air current assisted the removal of the vapour rising from the outer surface of the coil. We have in Degrand's arrangement, as it were, the germ of the principle of multiple evaporation, the latent heat of the steam escaping from the vacuum pan being employed for the performance of useful work. (Lantern slide.)

It is evident that the best manner of making use of this latent heat would be to immerse the cooling worm completely in the thin liquor and draw off the vapours by means of a vacuum pump. The exchange of heat would then become much more rapid than in Degrand's apparatus, and consequently more work would be obtained from a given amount of steam sent into the heating coil of the vacuum pan. In such an arrangement the vapours given off by the liquor in the vacuum pan—which we will now term the first vessel—must clearly have a higher temperature than the vapours leaving the second vessel for we can only obtain evaporation when a sufficient

difference of temperature is available. Now, if the temperatures of the two kinds of vapours are different, the pressures under which they stand must also be different. Suppose we are able so to arrange our appliances that we can obtain a practically complete vacuum, say a "vacuum" of about 700 mm. (27 ins.) (*i.e.*, an absolute pressure of 60 mm., or less than 3 ins.), then the vapour passing from the second vessel to the air pump would have a temperature of about 45° C. The temperature of the steam escaping from the first vessel must be higher than 45° C. In order to have useful work performed the difference should be, say, 30° C. Accordingly, the vapours escaping from the vacuum pan—our first pan—must have a temperature of 75° C., corresponding to an absolute pressure of about 288 mm. (11 ins.), or a "vacuum" of 472 mm. (19 ins.). If we allow the same difference—30° C.—between the vapours leaving the first pan and the heating steam, then the latter should have a temperature of 75+30=105° C. We thus see that we use the heat available in the steam of a temperature of 105° C. in two stages. Assuming that the steam is completely condensed, both in the heating coil of the first pan and in the coil of the second pan, then the latent heat of the steam has been used twice over, *i.e.*, we have obtained, with the help of this arrangement, double the effect. An apparatus of this kind has, therefore, been termed double effect, or double effect.

Some such considerations as these must have guided Rillieux when he constructed, about three-quarters of a century ago, his triple effect, *i.e.*, an evaporating apparatus consisting of three vessels in which the latent heat of steam is used three times over. The principle of his apparatus will be readily understood by considering a somewhat ideal case. Suppose we have at our disposal heating steam of what is termed in practice half an atmosphere pressure (or one and a half atmospheres expressed in absolute pressure), such as the exhaust steam from an engine. The temperature of such steam would be about 112° C. Suppose, further, that we have employed the best practical means for producing vacuum at the outlet of the third vessel so that the temperature of the vapours passing into the condenser would be about 46° C. We have, therefore, a temperature-difference of 112°—46°=66° C. available for evaporating purposes. This difference would have to be distributed over the three vacuum vessels or "effets." If we make the heating surface of each vessel the same, it follows that the amount of water evaporated will be the same in each vessel. Consequently, the difference of temperatures in the three vessels must be the same, *viz.*, 66/3=22° C. We have now the following state of affairs:—The steam entering the first effect has a temperature of 112° C. We require 22° C. for raising the liquor in the first vessel to the boiling point; the liquor would then have a temperature of 112°—22° C.=90° C., and the vapours escaping from the outlet the same temperature of 90° C. To this temperature of the vapour corresponds the absolute pressure of 525 mm., or, in technical parlance, a "vacuum" of 235 mm. (say, 9 ins.). A gauge (manometer) fixed to the outlet of the first vessel would, therefore, register this "vacuum." The steam enters the heating system of the second effect with a temperature of 90° C. The liquid in the second vessel requires 22° for raising it to the boiling point, and has, therefore, the temperature of 68° C. If no loss of heat takes place the temperature must be slightly higher, as the flow of liquid (which we shall consider later on) goes in the direction from the first effect to the second effect and the liquid coming from the first vessel has the temperature of 90° C., but this point may be neglected here. The vapour escaping from this second vessel will have the temperature of 68° C., which corresponds to an absolute pressure of 213 mm. (8.5 ins.) or a "vacuum" of 547 mm., say, 21.5 ins. This vapour of 68° C. enters the heating chest of the third vessel, and brings the liquid therein to the temperature of 46° C. The vapours escaping from the third vessel have the temperature of 46° C., corresponding to 75 mm. absolute pressure (3 ins.) or to a "vacuum" of 685 mm. (27 ins.). The water condensed in the heating chest of the first vessel is discharged under more than atmospheric pressure, and can, therefore, be run away without any special con-

trivance being required. The condensed water from the second and third vessels, however, being under a "vacuum" must be drawn off by separate pumps. In large installations the warm water is used for pre-heating the liquor. The flow of liquid usually takes place in the same direction as the steam vapours travel, *i.e.*, the liquor to be evaporated is drawn by the vacuum into the first vessel; the partly concentrated liquor is next drawn into the second vessel to be further concentrated therein and to be then drawn by the still higher vacuum into the third effect, where it is "finished" and discharged after final concentration, either by "breaking the vacuum" and letting the liquor run out under atmospheric pressure or by drawing it off with the help of a special pump.

Regarding the work that is done by the triple effect, it must not be assumed that three times as much liquor is evaporated in it as in a single effect with a heating surface of the size of any of the three vessels (which are made all of the same size). The following consideration will make this clear: With 1 lb. of steam we cannot evaporate in a single effect more than 1 lb. of water. The heat, both the sensible and the latent, inherent in the vapours, leaving the pan at 46° C., passes into the condensing water and is mostly lost unused. If we employ a double effect, then the steam passing from the first vessel into the heating chest of the second vessel gives off its latent heat and part of its sensible heat. We can, however, no longer have 1 lb. of steam escaping from the first vessel with a temperature of 46° C., as was the case in the single effect evaporator. As shown above, the steam will have the higher temperature of 75° C., and at this temperature, in conformance with the higher pressure, we can no longer have 1 lb. of steam removed from the first vessel, but only $\frac{1}{2}$ lb. of steam. Assuming perfect exchange of heat, we should now only require $\frac{1}{2}$ lb. of heating steam to enter the heating chest of the first vessel. The steam of 75° C. entering into the chest of the second vessel gives off its latent heat and will evaporate off $\frac{1}{2}$ lb. of water. We have therefore effected with $\frac{1}{2}$ lb. of heating steam the evaporation of $\frac{1}{2}$ lb. of water in the first effect, and of another $\frac{1}{2}$ lb. in the second effect, *i.e.*, we have evaporated off a total of 1 lb. of water with $\frac{1}{2}$ lb. of heating steam. We have thus used the latent heat of steam twice over; but it should be repeated, that although we have evaporated with $\frac{1}{2}$ lb. of steam twice that amount of water, the double effect itself has not evaporated more water than the single effect having the same heating surface as each of the vessels of the double effect. By working out analogous calculations in detail for any multiple effect, we find that we can evaporate off 1 lb. of water with $\frac{1}{2}$ lb. of steam in a triple effect, or with $\frac{1}{4}$ lb. of steam in a quadruple effect, with $\frac{1}{8}$ lb. of steam in a quintuple effect, with $\frac{1}{16}$ lb. of steam in a sextuple effect, or with $\frac{1}{32}$ lb. of steam in an octuple effect. Theoretically we can, therefore, evaporate with 1 lb. of steam 2 lb. of water in a double effect, 3 lb. in a triple effect, 4 lb. in a quadruple effect, 5 lb. in a quintuple effect, 6 lb. in a sextuple effect, and 8 lb. in an octuple effect.

We must, of course, make the proviso that there is always at our disposal a useful difference of temperature between, say, the 46° C. of the steam leaving the last vessel of the multiple plant and the temperature of the steam entering the first vessel. It is evident that the larger is the number of effects in a multiple apparatus, the higher must be the temperature of the heating steam. Adopting for a moment a temperature-difference of 20° C. as necessary for each vessel, we should have to add 20° C. for each vessel by which we wish to increase the triple effect. Suppose we employ in a triple effect heating steam of 112° C., then we must have for a quadruple effect 132° C., for a quintuple effect 152° C. for a sextuple effect 172° C., and 212° C. for an octuple effect. The pressures corresponding to steam of the temperatures named would be in the same order, expressed in round numbers, $1\frac{1}{2}$ atmospheres (=about 22 lb.), 3 atmospheres (=45 lb.), 5 atmospheres (=75 lb.), 8 atmospheres (=120 lb.), 16 atmospheres (=250 lb.). If we work, and it might be possible to do so, with a lower temperature difference than 20° C., say, 10° or even 5° C., the corresponding steam pressures might be reduced. But although the example chosen is a somewhat exaggerated one, it clearly shows the point I wish to bring out, *viz.*, that with a large number of effects the

steam (or boiler) pressure rises unduly and in a very disproportionate manner. This alone proves that in practice a limit must be placed on the number of effects that can be usefully employed. We must also consider that the losses of heat must necessarily increase with each added effect. Furthermore, bearing in mind the increased cost for a larger plant entailing high charges for depreciation, the increased cost for attendance, large space, &c., we find that these increases are not counterbalanced in a proportionate manner by the saving in coal, as theoretically the amounts of coal, in the above considered cases, are only reduced by $\frac{1}{2}$, $\frac{1}{4}$, $\frac{1}{8}$, $\frac{1}{16}$, &c. Besides, the fact must not be lost sight of that high pressure steam behaves almost like a gas and does not transfer the heat so economically as low pressure steam. In each special case it must, therefore, become a question of calculation how far the saving of coal is counterbalanced by the increased cost under the heads enumerated. I wish to lay stress on this point, as many a double effect and triple effect have been erected in works, where a single effect would have been the proper installation. It is impossible to lay down general rules, as each case must be considered on its merits, and only a careful calculation and consideration of all points involved can lead to a decision as to what number of vessels should be erected in a given case. It may, however, be said that the higher the price of coal the greater will be the benefit obtained by installing a large number of vessels. Thus it will be readily understood that a sextuple effect for the production of distilled water in the nitrate fields of Chili may prove a profitable installation, whilst similar plant in this country for evaporating brine would be a ruinous proposition.

An example taken from my own practice will perhaps better illustrate the foregoing remarks:—

A dilute caustic soda solution (from a causticising plant) had to be concentrated up to the sp. gr. 1.35. Calculation showed that in a given time 134 tons of water had to be evaporated off. The outlay for coal, having an evaporative power of 7.5, would have amounted for a vacuum evaporating plant consisting of

	S.
Single effect	to 496.0
Double effect 248.0
Triple effect 165.3
Quadruple effect 124.0
Quintuple effect 99.0

The saving effected by using multiple plant for the above given quantity would therefore be—

	S.	S.	S.
Between single effect and double effect ..	496.0—248.0=	248.0	
.. double and triple ..	248.0—165.3=	82.7	
.. triple and quadruple ..	165.3—124.0=	41.3	
.. quadruple and quintuple ..	124.0—99.0=	25.0	
.. single and triple ..	496.0—165.3=	330.7	
.. single and quadruple ..	496.0—124.0=	372.0	
.. single and quintuple ..	496.0—99.0=	397.0	

The numbers contained in the last table, in conjunction with some other considerations, such as available space, led to the decision that quadruple and quintuple effects would be too dear, whilst a triple effect presented an economical arrangement.

After this theoretical explanation we may now consider the apparatus used in practice. Rillieux, the inventor of the system of multiple evaporation, employed horizontal cylinders, furnished with a number of horizontal tubes arranged in locomotive boiler fashion. Some of the disadvantages of Rillieux's apparatus are the following:—The steam passes through all the heating tubes with a uniform velocity, and especially in the second and third effects with a low rate of velocity. It is, therefore, impossible rapidly to remove the condensed water and thus effect a rapid exchange of heat. As the tubes reach above the centre of the boiler, loss by entrainment is inevitable. The enormous advantages, however, which Rillieux's invention offered led to the fitting up of a number of installations in American factories, which worked very successfully. The introduction of Rillieux's system in Europe, especially in Germany, was not attended with equal success at first. The engineers, who undertook the erection of the apparatus from the drawings brought over, did not understand them and actually degraded Rillieux's

triple effect to a double effect. The troubles experienced with such a triple effect were such that it was jeeringly nicknamed "triste effect."

An important improvement in the apparatus was effected by Roberts (1850), who converted the horizontal effects into vertical vessels with much shorter heating tubes, thus giving to the vacuum vessels that form which is up to now the one most in vogue. In Roberts's vacuum vessels the steam circulates round a number of tubes of small diameter fixed in two tube plates. In an improved form of Roberts's apparatus a tube of larger diameter is fixed in the centre. The purpose of the centre tube was to assist the circulation of the liquid in the pan.

As long as solutions were boiled from which no solid substance separates during the boiling, an evaporator of this type would do fairly good work, as, for instance, when dilute solutions of distilled glycerin are to be freed from water. The only point that has to be considered is whether the heating chest is so designed as to afford, *cæteris paribus*, the best conditions for obtaining the highest efficiency from the heating steam. As soon, however, as solid substances, which are liable to cake on to the heating surface, begin to separate, a difficulty arises which becomes increasingly serious as the quantity of solids that become insoluble increases.

Sugar solutions, to which multiple evaporation was first applied, and for which this system has been worked out in a very thorough manner, present a comparatively easy problem, as the amount of solid matter that may cake on to the heating tubes is not very considerable. Still, the lime salts separating from the sugar solutions encrusted the tubes with the formation of a hard scale, which considerably reduced the coefficient of transmission of heat. In course of time this incrustation became so heavy, and the duty of the evaporation plant fell off so much, that it had to be laid off to be cleaned out. It is evident that an apparatus like Roberts's requires a good deal of manual labour, as each pipe must be cleaned separately. Although various devices were invented for cleaning the tubes they proved unavailing, and in the early days of multiple evaporation the incrustation of the tubes came to be looked upon as a necessary evil. When, therefore, the duty of an evaporation plant became too low, recourse was had to boiling out with acetic acid or hydrochloric acid, followed by caustic soda or caustic potash. The cleaning of horizontal tubes as employed in the old Rillieux apparatus was rendered easier by fixing the tubes in such a manner that they could be taken out singly. This led to the arranging in a bundle or chest of three or more horizontal tubes which could be taken out together and readily replaced.

Guided by the idea that the more rapidly the liquor circulates the quicker the condensed water can be discharged and the more efficiently can the boiling operation be carried on, a large number of inventors patented devices purporting to further these objects. It would be impossible to review here these patents, almost without number, and I must refer the reader to the extensive literature on sugar manufacture. The large central tube in the improved Roberts's apparatus had been credited with the power of creating so strong a current that the liquor rushing up through the narrow tubes and down the central tube would wash away all the solid substances—a pious assumption, which was not confirmed by practice. Great advantages were claimed for heating chests formed by a large number of bundles of tubes arranged as, e.g., in the Wellner-Jelinek apparatus. In order to be able to provide long tubes the circular form of the vacuum vessels was abandoned in this system, and the somewhat unsightly waggon-shape introduced. With a view to further increasing the heating surface, the bundles or chests of tubes were arranged in stages. This plan, which came much into vogue on the Continent and in the United States, permits the ready drawing out of bundles of tubes for cleaning. Another device for increasing the circulation of the liquid, and at the same time for rendering the cleaning of the tubes more easy is represented by the Aspinall drum (Fig. 1). The liquor can here rush round the whole of the heating surface; the drum is easily accessible and can be easily taken out.

A more modern arrangement, shown in Fig. 2, has given

FIG. 1.

FIG. 2.

me very good results as regards rapid circulation and economical use of steam. A similar arrangement has been lately re-patented in a multiple form, two or three of these drums being mounted in stages and furthermore the number of drums being doubled in addition to the fixing of a centre tube in the evaporator.

There is thus a complete ringing of changes in the arrangement of tubes—some of them clumsy devices for tormenting, as it were, the liquid in the hope of avoiding incrustation. Some of these devices seemingly create very rapid boiling, but what is frequently taken for boiling is caused by an eruptive bursting of the steam bubbles, which are generated at the lower portion of the heating chest and rush upwards, scattering the liquid when they burst.

In all the apparatus with horizontal tubes considered hitherto, the steam passes through the heating tubes, whilst the boiling liquid surrounds the tubes. A most important innovation was introduced by Yaryan, who sends the liquor through narrow tubes, whilst the steam circulates around them. The small diameter, in addition to a special feeding device, allowed a small quantity only of liquor to enter the tubes. The liquor is thus quickly heated, and the evolved steam forces it rapidly through the tubes. A much better evaporation was thus obtained, and it was hoped that in the case of sugar solutions, the deposits of salts would be prevented. An illustration of the Yaryan apparatus has been given already in this Journal (1889, p. 32). I show in two lantern slides a more

modern form of one of the effects and a quadruple effect, in which the condensed water is used for pre-heating the liquid. A further evolution of the Yaryan apparatus is represented by the Kestner vacuum evaporator, models of which were shown at the St. Louis Exhibition. It may be tersely described as a Yaryan evaporator placed vertically, though with somewhat longer tubes, so that the principle employed in the well-known Kestner emulsor is developed to the full, the liquid creeping up inside the tubes ("grimpage") whilst leaving an empty core.

Notwithstanding all these improvements, the incrustation of the tubes in sugar solutions still does take place. If the liquors in the succeeding vessels of the multiple plant travel in the same direction as the heating steam, they become, of course, specifically heavier, whilst at the same time, the temperature of the heating steam becomes lower. There is a compensation owing to the "vacuum" becoming increasingly higher, so that a more rapid removal of the vapours is obtained; yet, if the concentration of the liquid becomes too high, boiling would become so sluggish that it would be unremunerative to carry the concentration of sugar solutions too far in a multiple plant. It has therefore become the practice in sugar works to divide the plant for concentrating up to the finishing point into two main parts:—(1) a multiple evaporating plant, and (2) a single effect vacuum pan. When the thin liquors have been brought to a sufficiently high gravity in the first installation, they are pumped into a large single effect—the vacuum pan—which is heated by a row of coils with either exhaust steam or direct steam according to requirements. (Illustrations of installations consisting of a triple effect, having a wet pump, and a vacuum pan fitted with a Torricellian condenser and a so-called dry air pump were shown by means of lantern slides.)

Far more difficult to treat than sugar solutions in vacuum plant—single as well as multiple effect—are those solutions from which salts separate during concentration. The first attempt to apply multiple evaporation to solutions other than those of sugar was made, as far as I am aware, by Reynolds. He endeavoured to concentrate salt solutions in multiple apparatus, similar to one constructed by Derosne, which latter had designed a combination of the Howard pan and the Degrand pan. The apparatus became, however, choked with salt crystals, and we find Pécelet referring to this attempt with the somewhat hopeless words:—"Salt solutions can only be boiled down in multiple apparatus until they reach salting point."

A successful effort to apply multiple evaporation to "chemical solutions" was made by Dale in 1859 (Patent specification No. 506: "Improvements in concentrating caustic alkalis and in applying a product therefrom to the purpose of obtaining motive power and to other purposes"). Dale's process is well-known and is being carried out to some extent up to the present day. The boiling, however, did not take place *in vacuo*, as the steam leaving the first vessel was under a sufficiently high pressure to force itself through the heating chests of the succeeding effects; nor was the concentration carried further than to the point when salts would separate out. The liquor was then run into the caustic pot to be "finished" there in the well-known manner.

After a lapse of twenty years, a German potash works was induced by the success attending multiple evaporation plant in sugar works to experiment with their liquors (D.R.P. 14,015). The dilute lyes were concentrated in steam boilers, and the vapours were led into vacuum pans. The evaporation in the boilers over free fire was carried only to the "salting point," as further concentration would have led to separation of salt and burning through of the boiler plates. The vacuum pans were of the vertical type fitted with tubes. The separation of salts in them seems to have caused great trouble, for this system was soon abandoned. According to a later patent (D. R. P. 32,392, 1885), the order of the liquors was reversed, the first stage of the evaporation up to the "salting point" being carried out *in vacuo*, whereupon the concentrated solution was taken out and "finished" over free fire.

Meanwhile, in France, multiple evaporation *in vacuo* was adopted for the concentration of soda solutions. This

process was protected in Great Britain by a patent (E. P. 1527, 1881, J. Buffet: "Improvements in the method of effecting concentration and crystallisation of soda solutions and apparatus for the purpose"). The apparatus, consisting of a quadruple effect, was erected in the Etablissements Mulétra at Petit-Queville. The evaporation, however, was not carried beyond the salting point.

The introduction of multiple plant in chemical works, chiefly in Continental ammonia soda works, then became more general. We find that, at the beginning of the last decade, a number of multiple effects of the ordinary vertical type, as also of the Yaryan type (up to sextuple effects), had been installed for concentrating solutions of soda, caustic soda, potassium chloride, potassium carbonate, potassium sulphate, magnesium chloride, mineral water (Vichy), paper makers' waste solutions, and other waste liquors. In all these cases, however, the concentration was only carried on up to the point when salt began to separate. Attempts to go beyond this stage led to great difficulties and, notably in the case of the Yaryan apparatus, to failure.

The first serious attempt to grapple with the difficulty which solutions, if concentrated beyond the salting point offer, seems to have been made by Pick, whose first patent was taken out in the year 1887, under the name G. I. J. Wells, and was supplemented by a further patent (E. P., 3087) in the year 1890. The evaporating vessels, arranged as a triple effect, were of the ordinary vertical tube type. The special feature of the design was that the vessels had conical outlets, to which "salt filters" were fixed, into which the separating salt fell down and was washed and dried by suction. This was an adaptation from the conical pan and salting vessel which had been used successfully in the concentration of soap lyes for the recovery of glycerin. Undoubtedly, the bulk of the salt was thus removed, but equally certain is it that incrustation of the tubes took place. If the scale consisted of salt crystals only, the difficulty could have been mitigated by washing out with boiling water and occasional chipping away of the salt which had set hard. Far more serious was the trouble caused by the deposit of lime and magnesia salts which must be removed by hand. The purification of the brine previous to concentration would naturally suggest itself to the chemical mind, but this appears to be too expensive a process. For this reason, amongst others, evaporating plant for the production of salt from brine has not yet become a generally adopted process.

With the advent of electrolytic soda the question of the removal of salt from caustic soda solutions became more pressing. A liquor of this kind, with which I had to deal, contained about 4 per cent. of caustic soda and 4 per cent. of sodium chloride. Such liquor will throw out salt, when a density of a little over 60° Tw. (measured cold) is reached. It would thus only be possible to evaporate in multiple effect up to 60° Tw., or thereabouts; after that the trouble would commence. If it were intended to carry the evaporation further, the second and third vessels of a triple effect would have to be provided with "salting vessels." In order to prevent incrustation as far as possible, scraping arrangements were fixed in the tubular evaporators below the drum plates—again an adaptation from the method then employed in the recovery of glycerin from soap lyes. Of course, these scrapers could not keep the tubes clean, so that the old difficulty remained in full force. The pans were therefore worked as best as circumstances permitted, and the length of the working run, before the vessels had to be laid off for cleaning, depended entirely on the care with which the operations were conducted. When the duty fell off, the pans were emptied and washed out or, if necessary, cleaned out by hand. Some multiple effect plants were expressly so designed that one vessel could always be thrown out of the series for cleaning purposes. In fact, in the case of a sextuple and a triple effect within my experience, one vessel was always lying idle for cleaning purposes, so that, practically, only a quintuple and a double effect, respectively, were being worked.

It is obvious that working with evaporators under all these difficulties is not an ideal procedure. I was, therefore, led to design an evaporator (Fig. 3) which should

FIG. 3.

allow of continuous working and at the same time unite in itself all the advantages which are to be looked for in a useful vacuum vessel, such as rapid circulation of the liquid, rapid circulation of the steam, low level of liquid, prevention of entrainment, and, above everything, complete prevention of incrustation of the heating surface. The heating surface of my vacuum evaporator consists of a rotating chest, the construction of which varies according to the nature of the liquid which has to be concentrated. The heating chest is actuated by spur gearing, driven from the steam engine, which at the same time works the vacuum pump. The heating surface is kept free from incrustation by mechanical appliances. Thereby the salts are prevented from adhering to the heating surface the very moment they separate out from the solution, and they then drop through a sluice valve into a salting vessel. From this the salts are removed at suitable intervals without the boiling in the vacuum pan being interrupted. At the same time the revolving chest ensures the fullest possible circulation of the liquid, so that a rapid exchange of heat is assured.

The rapid circulation of the heating steam is also ensured by the revolving heater. The condensed water is rapidly thrown out, so that continually fresh contact of the heating steam with the heating surface is obtained. In order to arrive at definite numbers expressing the gain reached thereby, I made a series of experiments on a large working scale with heating surfaces of different types. The amount of water evaporated in a given time was measured carefully and simultaneously the quantity of steam sent through the heater was ascertained by weighing the condensed water. The quantity of water evaporated off, divided by the quantity of condensed water, gives the efficiency.

I experimented with a tubular heating chest of the old type, an Aspal drum, a drum similar to the one illustrated by Fig. 2, and the rotating heater. I found the efficiency in the old-fashioned tube evaporator to rise hardly above 80 per cent.; with the Aspal drum and the drum shown in Fig. 2 efficiencies up to 86 per cent. were reached. In the case of the revolving heater the efficiency was never found below 90 per cent. and varied

from over 90 per cent. to 93 per cent.; in some very favourable experiments even 94 per cent. were obtained. The level of the liquor can be easily kept at that height which experience shows to be the most suitable. By keeping the level below the top of the revolving heater, "film evaporation" can be obtained—an experiment which would obviously be very dangerous in the case of tubular heaters. The illustration (Fig. 3) still shows, as an entrainment preventer, the old-fashioned safe, in which the mechanically carried over liquor is trapped and led back into the pan. I have now abandoned this safe and replaced it by an entrainment preventer fixed inside the evaporator. Later on I shall demonstrate the work this entrainment preventer is capable of performing in three lantern slides.

I will now describe briefly a few practical applications of this evaporator to "chemical solutions."

Whereas in the concentration of caustic soda liquors in tube evaporators the sp. gr. of 1.35 cannot be exceeded with safety, I have evaporated caustic soda solutions in my evaporator to above 1.5 sp. gr. (measured hot). The salts which separate are withdrawn, as described already, and washed, whilst the boiling goes on uninterrupted.

An important application of my evaporator is found in the concentration of solutions from which calcium sulphate separates. The glycerin waters ("sweet waters") obtained in the so-called acid saponification processes contain sulphuric acid, which is usually neutralised by lime. A certain proportion of calcium sulphate remains dissolved in the glycerin solution and separates out on the heating surface as a hard scale. Formerly the evaporation of these liquors was carried out under atmospheric pressure, so as to have the heating coils readily accessible for periodical cleaning. In my evaporator the heating surface is kept perfectly clean as the sulphate is removed the moment it separates.

Practically the same problem, although in a more aggravated form, presents itself in the concentration of glucose solutions (as also of invert sugar). When tube evaporators are used in the concentration of glucose liquors, hard crusts of calcium sulphate settle down on the heating surface. A Yaryan evaporator would be practically useless for this kind of liquor as the cleaning of the tubes causes too much expense. Evaporators simulating the Wellner-Jelinek type are being largely used for this purpose, but the manufacturers have to put up with the trouble of pulling out the tube chests and cleaning them singly by boiling off the crusts with hydrochloric acid.

In the process of recovering glycerin from spent soap lyes, evaporation *in vacuo* has found a very important application. For many years the candle makers concentrated their "sweet waters" in the Wetzel pan. When the demand for glycerin brought the hitherto wasted soap lyes into requisition, this pan was also applied to their concentration; but as the surface of a coil does not lend itself readily to cleaning and scraping, Droux substituted for the coil a revolving cylinder. When the recovery of glycerin from soap lyes was introduced in this country, heating by steam was found to be attended by great inconveniences. The glycerin solutions were at first concentrated in open pots over free fire; in fact, the ordinary caustic soda pots, which could be easily scraped down whilst evaporation went on, were used. In order to prevent as far as possible the deposition of the salt on the heating surface, a large saucer was suspended in the liquid so that the bulk of salt could separate out on the saucer. This was lifted out at intervals by means of chain and pulley to clear it from salt. The liquid was not injured by the flue gases, as the concentration was finished at a temperature far below the one at which glycerin is decomposed. Since considerable quantities of glycerol volatilised towards the end of the concentration, the open pans were replaced by closed vessels, consisting of conical cast iron pans to which a salt vessel was fixed. The pans

were covered by a dome through which passed stirring gear, fitted with a set of scrapers by means of which the heating surface was kept clean. This arrangement worked very well and caused no loss nor even serious inconvenience, provided the material from which the pan was made was carefully selected. A large outlet pipe in the dome carried away the vapours. These vapours could now be used for pre-heating thin lyes or for their evaporation in multiple effect fashion. I used for this purpose rotating heaters. There was thus but a step to be made to the application of evaporation *in vacuo*. Vessels of the old tube type would obviously not do, and when they were applied, the inevitable happened. The tubes became rapidly salted up and endless troubles were encountered. Of course, by careful manipulation the trouble can be reduced to some extent, and various means were adopted to hinder incrustation. Thus, in some cases, the evaporators were completely emptied several times a day, and the deposited salt dissolved by charging the evaporator with thin liquors, or if need be with water. It is obvious that everything depended on the care of the manipulator, and I may say that I have seen some evaporators which worked for two days of the week, whilst the remaining days of the week were employed in chipping out the hard salt crust which had settled on the tubes. A more rapid circulation of the liquid, and consequently a washing away from the tubes of a large portion of the separated salt, was obtained by using evaporators fitted with a heating surface of the Aspinall drum type or of similar type. But even here very much depends upon the care with which the apparatus is worked. To avoid difficulties in small works, where work is only carried on during the day, the evaporators are emptied in the evening, and boiled out with thin lyes or with water, or where the operations are carried on day and night, the heating surfaces are cleaned by washing out after the

FIG. 5.

effect of this kind in Fig. 4. But I would not care to assert that this evaporating plant can be run for a full week, day and night, without the tubes becoming more or less coated with salt. The difficulty is, however, entirely removed by using my evaporator with the rotating heater. The double effect shown in Fig. 4 has, moreover, another important drawback. The thin liquid containing about 5 per cent. of glycerol enters the first vessel and is therein concentrated with the aid of exhaust steam until it contains about 10 per cent. of glycerol. The further concentration up to a content of 80 per cent. is carried out in the second effect. As the stronger liquid is heated with the steam coming from the first effect, the evaporation, especially during the last hours before finishing, becomes unduly slow. I find it, therefore, advantageous to imitate the sugar works practice, *viz.*, to concentrate in the double effect only up to a certain strength, and when the evaporation becomes sluggish to transfer the liquor to a single effect with rotating heater and to finish the batch therein. In the case of plant for smaller works, where a double effect *plus* a single effect would be too large, I reverse the direction of the flow of liquid by using the heating steam for the concentrated liquid, the dilute liquor being heated in the second effect by the vapours coming from the first effect. As no salts separate from the dilute solutions, the cheaper form of evaporating vessel, *viz.*, a tubular evaporator, can be used. This combination of a tubular evaporator with the rotating heater evaporator is shown in Fig. 5. Here the concentration of the soap lyes can be carried out throughout a whole week without the heating surface becoming encrusted.

The working of the liquors in the saltpetre making process offers a similar problem.

The nitrate of soda industry presents an example of a more complicated kind. The residue—*ripio*—remaining after the caliche has been boiled out and perhaps washed once contains considerable quantities of sodium nitrate, which can be extracted by further boiling out of the residue. The solutions so obtained contain considerable

FIG. 4.

finishing of each batch of crude glycerin. I speak from experience as I have myself erected for the evaporation of soap lyes evaporating plant fitted with tubular heating drums of the most advantageous type. I show a double

quantities of common salt and other impurities as the following analysis of a mixture of two successive washes—termed “relavés”—shows:—

	Grms. per litre.
Sodium nitrate	64.6
Sodium chloride	178.46
Sodium sulphate	20.17
Sodium iodate	1.95
Aluminium chloride	7.79
Calcium chloride	4.17
Potassium chloride	traces
Magnesium chloride	2.36

279.50

By concentrating these “relavés” the impurities are separated out until at last a saturated solution of sodium nitrate is obtained from which a commercially pure nitrate crystallises out.

Under the peculiar conditions of the nitrate fields the concentration can only be carried out economically by multiple evaporating plant, as the main product in this case must be distilled water, whilst the nitrate and the other salts recovered in the process can only be looked upon as by-products. Very soon after the concentration of the liquors commences calcium sulphate and then sodium sulphate separate out, which are bound to encrust the tubular heating surfaces in a very short time. The difficulties which this problem offers are best illustrated by the figures contained in the following table, which gives the composition of the salts as they separate successively on evaporation:—

	Calcium sulphate.	Sodium sulphate.	Sodium chloride.
	Per cent.	Per cent.	Per cent.
First “salts”	61.0	0.0	16.0
Second “salts”	8.3	0.0	87.8
Third “salts”	0.9	1.5	89.2
Fourth “salts”	0.85	3.5	83.3
Fifth “salts”	—	app. 75	app. 20

It is obvious that in a case of this kind the evaporator with the rotating heating surface is the most advantageous apparatus to employ.

As a last example, I take “distillers’ wash” (*distillers’ residue*). This is usually run from the stills into large ponds, where a certain amount of solid material subsides. The thin supernatant liquors are then run to waste, although they still contain large quantities of valuable food material. The concentration of these liquids in multiple vacuum plant has been attempted repeatedly, but all tubular evaporators have proved a failure. The suspended matter chokes up the tubes rapidly, and evaporation, therefore, falls off to such a serious extent that the boiling must be stopped after a short time. To make things worse the matter froths so incontinently that it is difficult to keep it in the ordinary pans. I have dealt with this material successfully in a double effect like the one shown in Fig. 5. The feeding stuff is recovered as a sludge and then treated similarly to the separated salts mentioned in the preceding examples. The special difficulty which the frothing offered was very effectively overcome by the entrainment preventer I have referred to already.

In this necessarily brief review I have been forced to omit all those processes which aim at the production of dry substances, such as are obtained from milk, blood, &c. Nor have I been able to consider any other heating agent than steam, although it must be obvious that the first effects of a multiple evaporating plant can also be worked with waste flue gases, when a high temperature is not injurious. Such a case is presented by the concentration of caustic soda liquors.

Enough has been said to show that each liquid requires special consideration and that the mere transference of a type of evaporator, which has been found useful in one industry, to another industry must be frequently attended with failure. This requires no further explanation to a chemist. To become more vividly impressed with the truth of this statement, it is only necessary to glance through the following list in which I enumerate, in addition to the substance mentioned already, some “chemical

solutions” to which evaporation *in vacuo* is applicable and has, indeed, been applied:—

Aluminium sulphate, ammonium chloride, borax, calcium chloride, ferrocyanides, lanoline from wool scourers’ wash waters, magnesium sulphate, potassium chlorate, potassium bi-chromate, potassium cyanide, saltpetre, sodium bi-chromate, sodium cyanide, sodium silicate, tartaric acid. Additions to this list will suggest themselves readily.

Before the designing of a suitable evaporator for any of these solutions could be approached, a thorough investigation of the behaviour of the solutions whilst undergoing concentration was indispensable. Nor did the study of the chemical side of the subject alone suffice. The material from which the evaporator, and especially the heating surface, should be constructed, had to be equally carefully considered in each special case. Thus, to take an example, an evaporator in which tartaric acid solutions are concentrated must not be made of iron nor of copper. Lead will suggest itself at once to the chemist. But, as the maker of fine chemicals may raise objections against lead, bronze will be the only comparatively cheap material that can be used in practice.

Here lies a wide field open, in which the chemist must co-operate with the engineer. It is but right to say here that I have worked together in this direction with Messrs. John McNeil and Co., engineers of Glasgow, with whom I have patented conjointly some of the special evaporating plant shown.

Perhaps it was owing to the want of such co-operation that the application of Rillieux’s system in chemical works other than sugar works was so long delayed. Possibly the chemist had not had the necessary engineering knowledge; or, perhaps, the influence of the mechanical engineer predominated in the works. Possibly even the time was not ripe, for this Society was not born until 50 years after Rillieux brought out his first multiple plant. It would be idle to speculate as to the reasons of the apparent neglect, since the enormous number of patents that have been taken out during the past 25 years seems to be making up for past neglect and a considerable number of workers are now busy in this domain, which is peculiarly that of the chemical engineer.

DISCUSSION.

The PRESIDENT, who was present, congratulated the meeting on having had such a valuable contribution brought before them.

Mr. J. BERNAYS said there were two statements which seemed to him rather to contradict each other. If he understood the author correctly, he said they must not expect a double effect or triple effect apparatus to do double or triple the work of a single one, but he afterwards clearly explained that in using the double apparatus, 1 lb. of steam would evaporate 1 lb. of liquor in the first vessel, and again evaporate 1 lb. in the second vessel, which would mean that in the two there were 2 lb. of liquor evaporated from the original pound of steam and if there was a third, 3 lb. That would, therefore, apparently mean that a triple apparatus should be three times as effective as a single, and a double apparatus twice as effective. With respect to the second point, he was rather surprised to hear Kestner’s evaporating system described as merely a turning over vertically of the horizontal tubes of the Yaryan apparatus. In Kestner’s apparatus, the tubes in which the liquor was contained were never full; the liquor never passed right through; there was no current. The liquor stood only about one-third high and the vapour carried the small particles of liquor right up to the end of the apparatus, and it was, therefore, supposed to be evaporated in a better and more economical way. The system seemed quite different from that involved in Yaryan and other evaporators, although to an outsider the apparatus might appear to be the same as Yaryan’s turned over, and it was surprising to hear it so described.

Dr. SCHACK-SOMMER asked why, when describing the double effect apparatus, did the author first take 30° as the difference of temperature between the liquor entering and leaving each pan; and afterwards, when describing the triple effect, only 22°. Did he mean to imply that the

effective heat was more in the former case than in the latter? One of the slides showed a vacuum pan with a Heizkörper and a central tube, and Dr. Lewkowitsch stated it was a "pious assumption" that the liquor would circulate better or move more rapidly on account of this central tube. Now he knew that a great many sugar chemists assumed that it was very essential that the liquor should circulate freely and move rapidly, and for this reason this centre tube amongst the steam pipes was much thought of, and Freitag patented a central tube that could be lengthened telescopically, following the surface of the liquor in the pan and similar devices had been the subject of various patents. Therefore he should like to ask if the author considered that the usefulness of the central tube was a fallacy or if in his experience it had not proved itself?

Mr. J. F. BRIGGS said a patent had been taken out this year in which it was attempted to obtain the multiple effect in a single pan. The patentee withdrew steam from above the boiling liquid by means of an injector of direct steam, and sent the mixture off into the steam drum of the evaporating pan. He should like to know whether that was a sound principle or not.

Mr. A. J. LIVEREDGE said the paper was full of interesting matter, and there were many points which would repay study. He would not like to convey the impression that he was adversely criticising Dr. Lewkowitsch's address, but he had made a singular error with regard to Yaryan's apparatus. He had said that in this apparatus the liquor was sent through the tubes; but that was not Yaryan's invention, because it was sent through tubes long prior to his time. He sent the liquor through the tubes in a limited quantity; that was Yaryan's invention. Again, the heaters on the Yaryan apparatus, shown on the screen, were the invention of Lilley (who was also an American), not of Yaryan. They were extremely valuable, because one of the reasons why there was a limit to multiple effect (and it was soon reached) was the necessity of raising the liquor to the boiling temperature in the first effect, and sometimes it might take as much heat to do that as to do the whole of the evaporation.

Dr. LEWKOWITSCH, in reply to Mr. Bernays' question, explained again the theory of multiple effect plant, and showed why a double effect with the same heating surface in each vessel did not evaporate twice as much as a single effect of the same heating surface, as is fixed in each vessel of the double effect. By utilising the latent heat of the steam in a double effect twice, one only required half the coal (or heating steam), but one had to pay for twice the size of apparatus. In his theoretical explanations he had avoided all complications occurring in practice, and assumed an ideal case where there was no loss of heat. As to the Kestner apparatus, he must acknowledge that he had been somewhat flippant, although he had said "with all due apologies to Kestner" in trying to explain its principle to an audience, which did not entirely consist of engineers conversant with evaporating plant. But he had mentioned that in Kestner's apparatus the tubes, besides being vertical, were much longer, and that the full effect of film evaporation—"grimpage" as it was called—was obtained. But to a general audience, which was only interested in the principles of the subject, the mere word, "grimpage," would not explain much, and he did not think he would have been justified in spending more of the time at his disposal in explaining the whole of Kestner's system. In reply to Dr. Shack-Sommer, the differences of temperature he had taken were quite arbitrary, although they were governed to some extent by the difference of the temperature of the heating steam and 46° C. He had tried to deal with the matter in the simplest way, and took arbitrary figures in order to bring out clearly the principle involved. He had had no experience of the telescopic arrangement to which Dr. Schaack-Sommer had referred, and therefore could offer no opinion about it. If the rapid circulation did actually do what was claimed for, there would be no deposit of salt on the tube, but

according to his experience, there always was. He did not deny the circulation, but he denied that it was strong enough to wash away the deposited salt. With respect to the question put by Mr. Briggs, he had seen that patent, and it had been abstracted in our Journal; as far as he remembered, it appeared to him to be more or less a recrudescence of the old system of Pecqueur in the twenties of the last century. Pecqueur, who is considered by some writers the father of multiple evaporation, had Rillieux in his employ as an engineer. But, as the latter could not convince Pecqueur of the advantages of his own system, he left in disgust for America, so that American sugar makers had the advantage of his invention long before European manufacturers. With regard to the Yaryan apparatus, he did not think he should have gone in his paper into all the different points that had been raised in a law suit between Lillie and Yaryan. The engineers who put up the Yaryan apparatus shown on the screen, used the pre-heaters, and whether the latter were Lillie's invention or not, did not concern his audience. He had not even mentioned Lillie in his paper. Lillie claimed many advantages for his film evaporation, which others disputed, but these matters were all outside the scope of a general paper of this kind.

New England Section.

Meeting held at Boston, on Friday, October 6th, 1905.

MR. HENRY HOWARD IN THE CHAIR.

The CHAIRMAN introduced Mr. Ivan Levinstein, past president of the Society, who offered a welcome, in the name of the older sections of the Society, to the New England Section. After a reference to the social and intellectual advantages of membership, and describing the Journal as the best technical chemical Journal in any language, he advised members to keep an eye on legislation affecting their interests, *e.g.*, spirit duties and patent legislation. In the course of his remarks on the latter subject, he traced the development of patent law, and pointed out inconsistencies between United States and British law.

APPLICATION OF ELECTROLYTIC CHLORINE TO TEXTILE BLEACHING.

BY H. S. DUCKWORTH.

In presenting this paper no claim is made for originality either in the application of electrolytic chlorine or in the apparatus for generating the same, but I shall try to show some interesting results from an apparatus with which we have now had nearly three years' experience. Mr. Charles H. Fish, Agent of Cocheo Manufacturing Co., read a paper before the New England Cotton Manufacturers' Association on this subject last year, and this paper treats of the same matter with a fuller discussion of our general results.

The idea of producing chlorine at the point at which it is to be used has been worked on for many years. There are two general systems for the electrolysis of brine solutions for the production of chlorine, depending on whether or not a diaphragm is used between the electrodes. With a diaphragm, chlorine and caustic soda are produced separately, without it they unite to form sodium hypochlorite, or what is generally known as electrolytic chlorine. The electro-chemistry of the decomposition of brine is very simple, and much time and money has been expended in New England on the mechanical arrangement of a cell that could compete successfully with the commercial bleaching powder, but the cost of working has generally been too high to begin with, the installation expense very large indeed and the up-keep of the apparatus very expensive, and, indeed, sometimes almost impossible to maintain. I have intimate knowledge of such a plant installed in a print

works at Lowell. This was a very ingenious arrangement of an electrolytic cell with a diaphragm which at the start off worked beautifully, but the maintenance grew heavier and heavier until finally, in disgust, the whole plant was thrown out. As far as I am aware the efforts of our American chemists seem to have been mainly towards a diaphragm cell, in which the chlorine is carried away and absorbed in milk of lime, and the resultant bleaching liquor must compete with identically the same compound made by dissolving bleaching powder. The chlorine in the liquor thus prepared is a little more active and efficient than in that made from bleaching powder, but that is all the advantage that it possesses.

The Haas-Oettel apparatus, which I am about to describe, and which is the subject of this paper, was originated by Dr. Felix Oettel. It has now been running continuously for three years at the print works of The Cochecho Manufacturing Co., and during that time not one cent has been laid out on it in the way of repairs. It consists of an electric cell or electrolyser made of asphalt composition, and placed within a water-tight tank, which tank is carefully insulated to prevent loss of electric current. The electrodes are on the so-called double pole system, that is, with one pole at each end of the apparatus and a number of intermediate electrodes that have no contact with each other, or with the current except as the current passes through the solution. The end or pole electrodes are of carbon, $\frac{3}{4}$ in. thick, standing vertically and extending completely to the bottom of the electrolyser. The intermediate electrodes are carbon plates about $\frac{3}{4}$ in. thick, fitting tightly across the apparatus in slides, thus subdividing it into numerous cells. These intermediate electrodes do not fill the entire space from top to bottom—they rest upon a non-conducting plate of the same thickness, and support a similar non-conducting plate that projects above the surface of the liquid. This latter arrangement is adopted for two reasons:

First.—Each cell thus constituted forms a dead or non-conducting space into which dirt and impurities, carried by the liquor, are deposited, without causing short circuiting or loss of electric energy.

Second.—The electrodes are covered with a head of liquor, and the bubbles of chlorine gas given off at the electrodes, pass through this head of liquor and are absorbed by it, with the result that there is not the slightest odour of chlorine in the room where the apparatus works. These separate cells have no communication with each other, but each cell has a small external opening at the bottom communicating with the brine in the tank, and one at the top also communicating with the brine in the tank. The tank itself is filled with brine until it is on a level with the opening at the top of each cell. The brine flowing through the openings fills each cell to the same level. When the current is turned on, a vigorous evolution of hydrogen gas ensues, which causes the liquor in each cell to be carried upward with the escaping gas, thus giving it a head of one-half to 1 in. over the brine in the tank outside the electrolyser. The brine, of course, flows out from the cell through the opening into the tank, and a corresponding amount is drawn in at the bottom of the cell to take its place. Thus there is a constant circulation caused by this evolution of gas.

The mode of working is as follows:—The apparatus is filled with brine to the proper level, and the switch thrown; the evolution of hydrogen begins at once and the circulation is entirely automatic and sufficient. A thermometer is placed in one of the cells to record the temperature, which should not exceed 28° C. The temperature is regulated by lead coils placed at either end, through which a part of the bleach house water supply is allowed to flow. A cross over switch is necessary in order to send the current through the apparatus in the opposite direction after every filling. This is in order to clean the carbon plates of the slight deposit of calcium and magnesium salts that form on it. It does this perfectly, and the plates are always clean. A fuse is placed in the current near the machine, so that if by any accident the apparatus should cease to circulate, no damage could result. The management is extremely simple and once rightly established an ordinary workman or even a boy

can obtain good results. No attendance is necessary except at the time of filling or emptying, although at first it is, of course, desirable to watch the temperature and make hourly analyses to be sure of the efficiency. At the expiration of the allotted time the plug at the bottom of the tank is drawn and the charge allowed to flow down into a storage tank, and the apparatus is flushed out with a hose, when it is ready for a second filling. The current used is a continuous one of 110 volts, such as is ordinarily used for lighting. No particular electric apparatus is necessary, although it is desirable to have an ordinary voltmeter or ammeter located at some convenient point in order to know exactly the conditions of the current.

The apparatus, as set up at the Cochecho Manufacturing Co., is contained in a tank 45 in. wide, 30 ins. long and 35 ins. deep, inside measure, although the first apparatus had a little larger tank holding a larger amount of liquor. It was found, however, that greater efficiency could be obtained by reducing the size of the tank and charging it, or refilling it with the solution more frequently.

The particular advantages as shown in this apparatus are as follows:—

- I. The initial cost is comparatively low.
- II. The up-keep of the apparatus costs very little, there being nothing to wear out except the electrodes, which are of carbon and inexpensive.
- III. There are no moving parts; no pumps or arrangements requiring attention. No power—it can be placed anywhere.
- IV. Simplicity in operation. Once adjusted, no supervision is required, and an ordinary boy can obtain good results.
- V. There is no waste of chlorine, and, therefore, there is absolutely no objectionable odour of vapours of any sort. The apparatus works cleanly, and can be located at any point convenient to the work.

From an experience of about three years of continuous running we can testify that the apparatus is quite efficient. It will be interesting to know that improvements in construction are now under way, looking towards even greater neatness, compactness and desirability, and we hope at the same time to show greater efficiency.

With the above apparatus, it is possible to produce in 5½ hours 126 galls. of sodium hypochlorite solution containing 14.4 grms. of chlorine to the litre, or a total of 6.86 kilos. of chlorine, or 15.12 lb.

Bleaching powder usually contains 35 per cent. of active chlorine, and allowing 8 per cent. for waste and loss in making up the solution, which is considered a fair amount, this 15.12 lb. chlorine would correspond to 45.36 lb. of bleaching powder, but here it must be noted that the electrolytic chlorine is much more efficient than the chlorine from the chloride of lime. Three pounds of electrolytic chlorine will, without doubt, do the work of 4 lb. of chlorine from bleaching powder, and therefore the 15.12 lb. of active electrolytic chlorine is equal to about 60.48 lb. of bleaching powder.

Table 1.

Capacity of tank=126 U.S. galls.=477 litres.
Brine at 211° Twaddell=169 lb. salt=76.66 kilos.
Horse power at \$15.00 per year—water power basis.

The above two tables show results from one run of the apparatus for 5½ hours. The time is limited to 5½ hours because this allows of two runs per *dium* of 12 hours for five days in the week, and one run on Saturday, which is in accordance with the usual hours of working of the textile industry in the East. Table 1 is based on a cost of horse power of 15 dols. per year—58 hours per week—water power basis. The cost of water power in New England varies greatly and figures are difficult to obtain, but in the Southern States, where water privileges are largely taken up and utilized by the textile industry, 15 dols. is considered a fair valuation. Table 2 is based on a cost of horse power of 25 dols. per year—steam basis. Most of our modern power plants can make as good a showing as this and some of them somewhat better. From an examination of the tables it will be seen that each electrolyser is capable of producing bleaching liquor equivalent to 121 lb. of chloride of lime in one day of 11 hours.

This question of cost is entirely one of location. The transportation of salt from Syracuse costs about 2.80 dols. per ton to the sea board. In this respect it is interesting to note that the present price of salt in Germany, denatured, with a little petroleum, is 60 pf. per 100 kilos. at the mines. This corresponds to 1.31 dols. per ton, which shows some difference as compared with our cost of 6.10 dols. delivered. Then, too, the German salt is somewhat purer than ours. Large concerns that have water power at their disposal, and oftentimes more than they can use, would find considerable economy in this process even when they are remote from the salt supply; while a concern that was obliged to depend upon coal for power, and distant from the coal fields and salt wells, could make no better showing than in Table 2, which is based on Dover, N. H. location—about as badly situated as any place in the Eastern States. Each concern must figure out for itself the pecuniary advantage of using such a process, which it can readily do from the tables and data given.

In enumerating the advantages claimed by the use of sodium hypochlorite, as against calcium hypochlorite for bleaching, I would say:

I. Intensely effective power of a nascent liquor and the great degree of permanence of whites obtained. It is well known that a gas in its nascent state is much more rapid and energetic in its action than one which has been stored. Moreover, the sodium hypochlorite is much quicker and more energetic in its action than the corresponding lime salt. There is no doubt that 3 lb. of electrolytic chlorine will do the work of 4 lb. of chlorine from bleaching powder, and will do it better, quicker and easier. It has even been claimed that the proportion of one to two will be nearer the actual condition and that even in this proportion the whites obtained by the electrochemical process will be purer and more permanent.

II. Universally greater strength and better appearance

and feel of the bleached goods. This is the most important factor in connection with this process and one upon which we cannot lay too much stress. We have made many experiments on cloth that has been boiled in the same kier, using hypochlorite of lime on one half and a corresponding amount of the sodium salt on the other, and invariably it is an easy matter for us to recognise the better feel, clearer white and better general appearance of that portion bleached with the sodium salt.

But even this is not the greatest advantage. The white obtained by the use of sodium hypochlorite is much more permanent, and, if the goods are intended for dyeing or printing, they will take the dyestuff much more evenly than the cloth bleached with hypochlorite of lime. In these days, when the tendency is to do a large part of the dyeing by means of a padding machine, the advantage gained is enormous. We believe this advantage of permanency of whites and level dyeing is largely due to the absence of lime salts in the fibre, although they may be partly explained by the greater solubility, and consequently penetrating power of the sodium salt. No one will dispute that it is difficult, indeed almost impossible, to absolutely free the fibre from lime salts after treatment with bleaching powder solution. This lime salt deposited unevenly over the fibre even in the minutest quantities interferes with the even dyeing of many colours. It seems reasonable that if a less amount of chlorine is used, and when that is expended, nothing but a small amount of common salt is left in the goods, they will be in better condition than where the greater amount of chlorine is used with the accompanying solution of different lime salts.

III. Less acid is required after "chemicking," while for many purposes only a slight washing is necessary, as the small amount of salt in the fibre will not interfere with subsequent operations.

IV. It is of especial advantage in clearing the whites in printed goods. The whites are more easily cleared, and the colours suffer less. We believe that many industries would find places for this where the lime salt is very troublesome and often entirely prohibitive.

V. The process is much cleaner and vastly more satisfactory to deal with than the ordinary process with bleaching powder.

It can be readily understood that this process is not only applicable to the whitening of cotton in any form, but it is especially adapted to the bleaching of flax, which, being difficult to bleach, suffers more from the action of hypochlorite of lime than from sodium hypochlorite. It is also applicable to the fibres used in paper making, also to the bleaching of jute, oil, artificial silk, viscose compounds, and in fact to any process where bleaching powder is now used. This process is largely used in linen bleacheries in Germany, where they often chemie the goods four or even six times. The destructive action of the lime salt on linen is well known, and goods bleached by the electro-chemical process are vastly stronger, and, indeed, are considered equal in this respect to the old grass bleach. This process is of especial use for laundries, and a small cell is made for them and other small users of chlorine. This little apparatus is complete in itself, containing brine tank, electrolyser and storage tank. It is made entirely of porcelain, and covers only a few feet of floor space. It will produce at very slight expense for running 3 kilos. of chlorine per *dium*, which is enough for most laundries, and the advantages of hypochlorite of sodium over lime for laundry use would be many.

It is to just such uses as these that we believe hypochlorite of sodium could advantageously be put. We have in mind a very successful concern who make hosiery and underwear. Their goods are made largely from Egyptian cotton, and they have much trouble from the goods yellowing after being put up in the boxes. From an investigation of their trouble I became convinced that it was due to the lime, and it could be absolutely avoided by the use of sodium hypochlorite. This concern used about a cask of bleaching powder in two weeks. One of these Haas and Oettel apparatus, charged once a day, would give them all the chlorine they need, and the expense of installation and extra expense of operation would be a mere bagatelle as compared with the value of

their goods. Indeed, in such a case I doubt if there would be any increase in cost of working, for a cask of bleaching powder after it has been opened for two weeks has lost a substantial part of its chlorine. I believe there are many industries now using small amounts of bleaching powder, like the instance referred to, where one cell or two cells could be most advantageously installed and where any increase in cost of working would be of small consequence compared with the advantages gained.

In summing up, we claim for the process that it is simple, complete, and more satisfactory in every way than the use of bleaching powder, and while to a plant using a large amount of chlorine and not advantageously situated as regards salt and fuel, we could show no financial advantage even to them, when all other advantages are considered, we believe this process would still show up on the right side. To small users of chlorine, and especially where the value of their product is great or the process of bleaching difficult, and where any improvement would be gladly welcomed, this system should prove a great success and a solution of many difficulties.

DISCUSSION.

Dr. H. CARMICHAEL said he had been interested in the application of hypochlorites somewhat extensively in other fields, especially that of paper pulp bleaching. He thought that more data should be given such as current density, voltage, and chemical efficiency. It was a mistake to consider chlorine in one combination as hypochlorite to be more efficient than another. There was a difference in time of reaction, but not in real work accomplished. Cross and Bevan some years since investigated the action of magnesium and calcium hypochlorites, with the above result, although at first they were deceived by quickness of action of the magnesium compound, and really considered it more efficient. Sodium hypochlorite came between magnesium and calcium hypochlorites in speed of reaction. He would be glad to have some data on the use of magnesium chloride. He preferred platinum to carbon electrodes; the investment with platinum electrodes was, of course, much greater, but there was no depreciation with properly regulated apparatus, while with graphitised carbon electrodes the expense of renewal every year and a half or so at 10s. per lb. would be considerable. The production of sodium hypochlorite was accompanied by low chemical efficiency. With the "Cooper" apparatus it had been found advantageous to separate caustic soda and chlorine and then recombine them. It was still cheaper, however, to absorb the chlorine in milk of lime, and utilise the caustic soda elsewhere. The bleaching liquor made thus was more efficient than liquor of same strength made from bleaching powder. He would like an explanation of this fact, which he had frequently observed. His remarks applied specially to paper pulp bleaching, and he could see that perhaps for textile fabrics there would be some advantage from the use of sodium hypochlorite.

Dr. W. H. WALKER said that when Dr. Carmichael assumed that solutions of the different hypochlorites having the same content of available chlorine must also possess equal bleaching power, he was confusing ability to oxidise with ability to bleach. Factors other than content of available chlorine were of influence in the bleaching operation. At least three of these factors were the following:—

First, the extent to which the solutions were hydrolysed. Calcium hypochlorite as made from bleaching powder was necessarily saturated with calcium hydrate, while sodium hypochlorite made by direct hydrolysis was neutral. The presence of the alkaline calcium hydrate drove back the hydrolysis of the calcium hypochlorite, thus rendering it less active.

Second, the presence of carbonic acid. This acid was capable of forming free hypochlorous acid, which in turn, being the most unstable of these compounds, was the most active bleaching agent. The bleaching process, consisting of the oxidation of unstable organic colouring matter, was always accompanied by the formation of carbon dioxide. In the case of bleaching powder solutions

the calcium hydrate present united with this carbon dioxide, thus taking it out of the sphere of action and precipitating calcium carbonate on the fibre. In sodium hypochlorite, on the other hand, the action of carbon dioxide was cumulative, and accelerated rather than retarded the bleaching process. Third, experiments performed some time ago with the use of colloidal plugs of agar-agar showed that the speed of penetration of sodium hypochlorite was greater than that of the calcium salt. The effect of these factors in practice was to produce by sodium hypochlorite a more uniform and permanent colour, free from oxycellulose or over bleaching, and a more efficient utilisation of the oxidising power of the solution. The harsh feel of the goods, alluded to by Mr. Duckworth, was, in part at least, accounted for by the calcium carbonate precipitated on the fibre by the carbon dioxide formed during the reaction, and which was not easily removed by scouring.

The CHAIRMAN asked on what basis the cost per horse power, given in the tables, was arrived at?

Mr. C. H. FISH said that Mr. Duckworth's figures were very conservative. He had much to do with the apparatus, and had adopted it for use as a part of the regular equipment in the works over which he had charge. All the apparatus was purchased in Germany and brought over to America, set up, and started without any trouble whatever. It was put in to increase the capacity of the bleaching department. The second apparatus purchased and brought over later was installed, and in some respects was an improvement over the first. Possibly this apparatus was not particularly suited for large plants with high power cost, but was well adapted for units or for small plants where cost of power was not material. In any case, there were many attending advantages difficult to show or explain, but which were made apparent in and about the bleaching department, where the difficulties arising from the corrosion of piping and the destruction of floors and timber was obviated, to say nothing of the advantages to employees who, through the use of commercial bleaching powder, suffer great personal inconvenience. He thought in time sodium hypochlorite produced by this apparatus in a possibly improved form would supersede the use of bleaching powder to a very great extent.

Mr. F. E. ATTEAUX asked if the superior quality of bleaching would not offset the additional cost?

Mr. FISH said that for many classes of goods, especially of high-priced goods or those of delicate texture, the increased cost, if any, would certainly be offset by the improved quality of the product. It was especially applicable to hosiery and knit goods, while the application to laundry work was likely to be very extensive. The proprietors of a large laundry in the West stood ready to give orders for 100 apparatus whenever they could be delivered. The freedom from lime and regularity of product made it especially desirable for laundry work.

Mr. DUCKWORTH said, in reply to Dr. Carmichael, that, as he stated in the beginning of his paper, no originality either for the apparatus or for the application of hypochlorite was claimed. His object was to show the desirability and feasibility of using the sodium salt, as generated by the Haas-Oettel apparatus. The magnesium salt was out of the question, both on account of price and also because the slightest amount left in the fibre would seriously interfere with subsequent operations. He felt sure from the testimony of users in Germany that the main objections to apparatus with platinum electrodes had been the expense of repairs and renewal. The cost of a whole set of carbons was only a few dollars. Dr. Walker's remarks had very ably answered the question of Dr. Carmichael as to the efficiency of the sodium salt over the lime salt. He thought that the difference of opinion between Dr. Carmichael and himself was largely due to the fact that one had worked on wood pulp and the other on cotton fibre, and the conditions in the two cases were far different. In reply to Mr. Howard, the price given in the tables for horse power was figured on the 58 hours per week basis.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—8d. each, to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—1s. each, to the Secretary of the Society.

French.—1 fr. 25 c. each, to Belin et Cie, 56, Rue des Francs-Bourgeois, Paris (3^e).

I.—PLANT, APPARATUS, AND MACHINERY.

(Continued from page 1101.)

ENGLISH PATENTS.

Separating Liquids; Methods of and Means for ——. E. G. N. Salenius, Stockholm. Eng. Pat. 22,878, Oct. 24, 1904.

SEE U.S. Pat. 784,231 of 1905; this J., 1905, 428.—T. F. B.

Furnaces; Impts. in Reverberatory ——. B. E. Eldred, New York. Eng. Pat. 25,832, Nov. 28, 1904.

THE claim is for increasing the volume and reducing the temperature of the flame of reverberatory furnaces by burning the fuel in a practically closed chamber supplied with a mixture of air and waste chimney gases in predetermined proportions. Further, the temperature of the furnace bed can be locally raised by injecting compressed and preheated air through jets projecting downward and placed at various points successively along the furnace roof. Claim is made for the slide-valve mechanism for controlling the supply of compressed air. —W. H. C.

Volatile Liquid from Air and Gas; Impts. in and Apparatus for Effecting the Recovery of ——. by Refrigeration. E. Hesketh, London. Eng. Pat. 1287, Jan. 23, 1905.

THE air to be treated is first passed through the tubes of a horizontal tubular "interchanger," and thence to a refrigerator, where the volatile liquid and moisture are condensed. The treated air from the refrigerator is returned to the "interchanger" and circulates around the outside of the tubes. A spray of water injected into the upper part of the "interchanger" saturates the treated air with moisture. The latent heat absorbed by the evaporation of this moisture assists in the preliminary cooling of the untreated air.—W. H. C.

Filters; Impts. in ——. T. Seitz, Kreuznach, Germany. Eng. Pat. 10,538, May 19, 1905.

THE liquid to be filtered enters a pressure vessel fitted with a number of parallel filter elements, each consisting of a frame carrying a sheet of fine gauze or the like on either side with intermediate screens or gratings, the frame walls being more or less open towards the screens and provided with draw-off branches to facilitate a quick outflow in all

directions and a uniform distribution of the filtering medium. The frames are constructed to take apart in the direction of their length. The containing vessel is cylindrical or oval in plan, and the removable filter elements are arranged in vertical rows, parallel to a diameter of the vessel if circular, and to an axis or other secant of the vessel if oval.—C. S.

Gases; Method of and Apparatus for Separating Mixed ——. C. Clamond, Paris. Eng. Pat. 17,946, Sept. 5, 1905. Under Int. Conv., Sept. 12, 1904.

SEE Fr. Pat. 346,195 of 1904; this J., 1905, 78.—T. F. B.

UNITED STATES PATENT.

Drying Pasty and Liquid Materials; Apparatus for Quick ——. A. Huillard, Suresnes, France. U.S. Pat. 802,541, Oct. 24, 1905.

SEE Eng. Pat. 18,978 of 1904; this J., 1905, 916.—T. F. B.

FRENCH PATENTS.

Crystallisation; Process for ——. G. Schlicht, Fr. Pat. 354,522, May 22, 1905.

BASKETS having hollow sides (jacketed) through which a liquid or gaseous refrigerating agent is circulated, are placed in the liquid from which the crystals are to be deposited. When the baskets are covered with crystals, they are withdrawn from the solution and the crystals are detached by circulating a heating agent through the hollow walls.—W. H. C.

Solvents; Process for the Recovery of the Vapours of Volatile ——. Soc. J. Jean et Cie. and G. Raverat. Fr. Pat. 350,149, Sept. 1, 1904.

THE mixture of air and of vapour to be recovered is caused to bubble through glacial acetic acid or phosphoric acid contained in a suitable vessel. The vapour enters into combination with the absorbent and is retained, the air alone passing away. By suitable treatment of the resulting compound the condensed vapour may be again separated. For example, the compound of acetic acid and the vapour of benzene may be diluted, when the separated benzene will float on the diluted acetic acid and may be decanted, while the acetic acid, after concentration, is ready for use over again.—W. H. C.

Hydro-Extractor. N. S. Bök. Fr. Pat. 355,962, April 25, 1905. Under Int. Conv., April 27, 1904.

THE invention consists of a distributor for hydro-extractors divided into isolated separation chambers, the distributor being composed of a hollow fixed or rotatory body, fitted with outlet orifices of such dimensions that the volume of liquid delivered by them to the separation chambers is uniform in the case of each horizontal row of the orifices in question.—C. S.

Centrifugal Apparatus for Separating Solids from Liquids ; Impts. in —. Aktiebolaget Separator. Fr. Pat. 354,416, May 18, 1905. Under Int. Conv., May 27, 1904.

THIS is an improvement on Fr. Pat. 342,115 of 1904 (this J., 1904, 895), and consists in using obliquely inclined scrapers to remove the separated solids from the drum of the separator.—W. H. C.

Centrifugal Apparatus for Separating Solids from Liquids ; Impts. in —. Aktiebolaget Separator. Fr. Pat. 354,417, May 18, 1905. Under Int. Conv., May 27, 1904.

SEE Eng. Pat. 10,862 of 1905 ; this J., 1905, 958.—W. H. C.

Liquids ; Apparatus for Raising—. Giesserei und Maschinenfabrik Oggersheim Paul Schütz. Addition dated June 2, 1905, to Fr. Pat. 314,314, Sept. 18, 1901.

THE delivery pipe of the apparatus is fitted with a hydraulic seal, into the compression chamber of which debouches a siphon tube.—C. S.

Liquids or Mixtures of Liquids ; Process and Apparatus for Mechanically Rendering — Homogeneous. Deutsche Homogenisiermaschinen-Ges. Fr. Pat. 354,943, June 5, 1905.

THE liquid or mixture of liquids, after a preliminary mixing in a tank provided with an agitator having perforated blades, is forced by a pump through a tube in which a rod with spiral grooves and which terminates in a cone is placed. The passage of the liquid along the grooves causes the rod to rotate and the liquid is pulverised between the cone and the walls of the tube.

—W. H. C.

Water from the Washing of Coal, Minerals, &c. ; Process for the Clarification of Residual —. F. Baum. Fr. Pat. 355,097, June 8, 1905.

A PROCESS is claimed by which the muddy wash water is conveyed into a settling tank, from the bottom of which the thick mud is abstracted, and after partial drying, is delivered on to the upper surface of the large particles of waste, as they are conveyed to the dump, by a continuous (endless) band transporter.—W. H. C.

High Vacua ; Production of —, and Cooling by Evaporation. C. A. Parsons. Fr. Pat. 355,181, June 13, 1905. Under Int. Conv., June 21, 1904.

THE claim is for the production of high vacua in coolers and condensers by the use of one or more vacuum intensifiers ("augmentateurs de vide") along with a system of condensers. The vacuum intensifiers are in the form of the well-known steam injector, but have the jet through which the steam enters very much constricted at first and then gradually widened out into a funnel- or trumpet-shaped portion, the diameter of which is many times that of the constricted portion. The high vacuum attained, when these intensifiers are worked in series and combined with suitable condensers, accelerates considerably the evaporation in the space from which they exhaust, and rapid cooling of the liquid contained therein ensues.

—W. H. C.

Powdered Substances ; Method of Facilitating the Moistening of —. Act.-Ges. für Anilin-Fabrication. Fr. Pat. 355,440, June 21, 1905.

THE substance to be moistened is intimately mixed with $\frac{1}{2}$ –3 per cent. of soap, the latter being either ready made or produced during the operation of mixing.—C. S.

GERMAN PATENTS.

Liquids, especially those containing Carbonic Acid ; Process and Apparatus for the Purification of —. Act.-Ges. Fabr. f. Brauerei-Einrichtungen vorm. H. Gehrke and Co. Ger. Pat. 161,025, March 17, 1903.

THE process, which is intended specially for the clarification of liquids containing dissolved carbonic acid, consists in passing the liquid under pressure through a centrifugal separator in which filter-elements are disposed parallel to the cover of the apparatus. The solid impurities are deposited on the inner walls of the separator, whilst the liquid is led away through the filter-elements. If necessary, a float or hollow chamber is provided in the separating space of the drum of the centrifugal apparatus, in order that the volume of unfiltered liquid in the separator shall not become too large.—A. S.

Evaporating Apparatus ; Vertical —. A. Guder. Ger. Pat. 160,670, Feb. 23, 1904.

THE apparatus is of the type in which the liquid to be evaporated passes through heating tubes which are surrounded by the heating agent (steam). FIG. 1 is a vertical and FIG. 2 a horizontal section of the apparatus. The steam enters through the openings *b*, and passes into the heating chamber through vertical slits, *m*, in the mantle, *l*. The heating tubes, *e*, are fixed between the plates, *c* and *d*, and the condensed water from the steam is led away through the pipe, *f*. The liquid to be evaporated enters through the pipe, *g*, and distributor, *h*, the latter opening into a number of tubes, *i*, which deliver the liquid to the outer group of heating tubes, separated by the ring, *k*, from the inner group of tubes which are not supplied with liquid. The liquid rises in the outer tubes, which come in contact with the hottest steam, and is thrown out at the top; after the disengagement of steam bubbles, it descends through the tubes in the inner group, the steam surrounding which is at a somewhat lower temperature. It is claimed that the heating agent (steam) is kept in vigorous motion,

so that uniform heating is attained, which, combined with the regular circulation of the liquid through the tubes, prevents incrustation.—A. S.

II.—FUEL, GAS, AND LIGHT.

(Continued from page 1103.)

Sulphur in Spent Oxide; Determination of Free —. O. Pfeiffer. XXI., page 1194.

ENGLISH PATENTS.

Fuel and other Briquettes; Manufacture of —. L. Márton, Budapest, Hungary. Eng. Pat. 24,755, Oct. 10, 1904.

SEE Fr. Pat. 347,092 of 1904; this J., 1905, 270.—T.F.B.

Fuel Briquettes; Apparatus for Treating —. B. Wagner, Berlin. Eng. Pat. 241, Jan. 5, 1905.

SEE Fr. Pat. 350,536 of 1905; this J., 1905, 721.—T.F.B.

Fuel; Agglutinants for use in Solidifying Pressed —. R. Middleton, Leeds. Eng. Pat. 347, Jan. 7, 1905.

A DRYING oil is partly oxidised (this operation not being carried too far) and used as a waterproofing and enriching binder for dust fuel, the ingredients being incorporated in a mixer fitted with knives or beaters, and then passed forward to the pressing rams and consolidated under heavy pressure.—C. S.

Fuel; Combustion of Liquid — [under Water-Tube Boilers.] Sir W. G. Armstrong, Whitworth and Co., Ltd., E. L. Orde, and W. H. Sodeau, Newcastle-upon-Tyne. Eng. Pat. 25,578, Nov. 24, 1904.

A NOZZLE for spraying oil is directed into an aperture in the front of the furnace, the nozzle and aperture being surrounded with an air chamber for the supply of compressed air. By this means a stream of air is caused to surround and be impelled in the same direction as the spray of liquid fuel, with velocity sufficient to enable it to retain approximately its initial direction and form until it has reached the region of active combustion within the furnace, by which time the spray will have become intermixed with several times its weight of air.—H. B.

Gases; Method of Treating Distillation — to Obtain an Illuminating Gas in a Highly Compressed Form, suitable for Transport. H. Blau, Augsburg, Germany. Eng. Pat. 23,675, Nov. 2, 1904. Under Int. Conv., Nov. 2, 1903.

Distillation, especially of Tars or Tarry Products, and for use in the Manufacture of Carburetted Water Gas and like Processes. G. Wilton. Eng. Pat. 25,879, Nov. 28, 1904. III., page 1165.

Gas Producers; Impts. in —. E. Hall-Brown, Glasgow. Eng. Pat. 27,571, Dec. 17, 1904.

A PRODUCER, for use with bituminous fuel, of the type in which the tarry gases collecting above the fuel are led downwards and passed through the incandescent zone, is provided near the top with an outlet pipe, fitted with a steam or air injector nozzle, by means of which the tarry gases are drawn off and delivered into casings at, or near, the level of the fire-bars or combustion zone. From these casings the tarry gases pass through numerous door-controlled inlets, at different levels, into the incandescent fuel. At a suitable level or levels for drawing off the fixed gases, channels are provided in the walls of the producer, these channels communicating with the interior of the producer through several door-controlled openings, and with the outlet pipe for the final discharge of the fixed gas.—H. B.

Gas; Material or Composition for use in Manufacturing Air —. W. Moores and A. A. Bailey, London. Eng. Pat. 11,751, June 5, 1905.

CARBURETTED air is produced by forcing air through a pulp composed of wood, fibre, paper, or the like which has previously been saturated with a "solution" of alum $\frac{1}{2}$ oz., quicklime 2 oz., caustic soda 2 drms. in 2 galls. of water, and to which, after drying, a quantity of benzoline has been added.—H. B.

Gas Producers; Impts. in —. W. Towns, Liverpool. Eng. Pat. 14,090, July 8, 1905.

A GAS producer for use with bituminous fuel is provided at the top, and to one side, with a purifying chamber containing incandescent coke or other non-bituminous fuel, through which the tarry gases from the producer are passed. The coke is kept incandescent by means of an air blast, introduced at the foot of the chamber at a point opposite to that at which the tarry gases enter.—H. B.

Gas Generators; Apparatus for Supplying and Vaporising Water for —. A. Illy, Paris. Eng. Pat. 14,334, July 11, 1905.

THE admission of water vapour to the generator, which is of the suction type, is regulated automatically by means of the pressure and heat of the exhaust gases of the engine, fed with the generator gas. In one form of the invention, a part of the exhaust gases is discharged through a branch pipe from the main exhaust, the pipe being contracted at one point to form an injector nozzle; the injector is surrounded by a chamber which communicates with another chamber containing a flexible diaphragm, which carries the valve of the water reservoir. At each blast of exhaust gases through the injector, a partial vacuum is created in the said chambers, the valve of the reservoir is raised, and a certain volume of water is admitted to the vaporiser. The vaporiser consists of a series of blades fixed to the exterior of a vertical portion of the main exhaust pipe, which is enclosed in a casing through which the air required by the generator is drawn at each suction stroke of the engine. The air is thus heated by contact with the exhaust pipe, and carries off the steam produced as the water from the feeding device falls upon the blades. Other forms of feeding device are described.—H. B.

Washers or Scrubbers for Purifying Gases; Construction of Rotary —. R. W. B. Creeke, Leven, Fife, N.B. Eng. Pat. 27,820, Dec. 20, 1904.

A NUMBER of circular brushes rotate upon a horizontal shaft arranged within a rectangular casing having an arched upper part. Each brush is somewhat drum-shaped, consisting of two end drum cheeks, keyed to the shaft and surrounded by two concentric drums of staves, filled with bass fibre. The lower part of the scrubber is divided into a series of troughs by means of partitions extending downward from the shaft, so that each brush dips into a separate trough. The gas to be purified passes through the apparatus in one direction, finding its way through the wet fibre of the brushes, whilst the wash-liquor flows through from trough to trough in the opposite direction.—H. B.

Gas from Gas Producers, Blast-Furnaces and the like: Method of and Apparatus for Purifying the — J. E. Thornycroft and John I. Thornycroft and Co., Ltd., Chiswick. Eng. Pat. 28,295, Dec. 23, 1904.

WATER alone, unmixed with air, is forced, in the form of spray or mist, into the gas on its way from the producer or furnace to the gas engine, the moistened impurities being removed before the gas enters the engine. The crude gas passes down and then up through a vertical casing, divided into two compartments by means of a depending partition, and encounters therein vertically directed streams of spray or mist, which issue from nozzles fed with water by a pump driven by the gas engine. Some of the water and impurities collect at the bottom of the casing; the others are removed in a separating chamber, through which the gas next passes, the gas, issuing from a "rose" at the end of the inlet pipe, being bubbled through water in fine streams. The purified gas then enters the cylinder of the gas engine.—H. B.

Gases: Impts. in Purifiers [Washers] for — W. Towns, Liverpool. Eng. Pat. 10,993, May 26, 1905.

A HORIZONTAL, cylindrical casing is divided into several compartments by means of diaphragms having central openings. A central shaft extends horizontally through the casing, supporting a rotating fan or disperser in each compartment. The fans are formed of discs with blades on one side, and are arranged close to the diaphragm at one side of the compartment so that the blades face the gas which enters through the central opening. Pipes are provided for introducing water, through each central opening, into the fans, and water-sealed outflow pipes at the bottom of the casing serve to lead off the wash water and impurities.—H. B.

Water from the Washing of Coal, Minerals, &c.; Process for the Clarification of Residual — F. Baum. Fr. Pat. 355,097, June 8, 1905. I., page 1162.

Coal; Method of Enriching Small Lean — H. Koppers. Fr. Pat. 355,355, June 19, 1905. III., page 1166.

Furnace for Long Gas-Retorts; Double Generator — Stettiner Chamotte-Fabrik A.-G. vorm. Didier. Fr. Pat. 355,135, June 10, 1905.

EACH set of retorts is heated by means of a single generator, which is charged from one side of the bench only, and is so constructed that one portion of the generator gas is used for heating the rear halves of the retorts, and the other portion for heating the front halves of the retorts. The retort setting is divided by a transverse partition into two compartments, the one containing the rear half of each retort, with appropriate combustion and air flues, and the other the front half, with similar flues. A transverse wall depends from the top of the generator downwards, some distance into the body of fuel, thus forming front and rear generator chambers, which communicate with each other through the bed of fuel only. The gases from the

rear chamber pass upwards through the rear portion of the retort setting, whilst those from the front chamber rise through the front portion, the quantities of gas led through the respective portions being regulated by means of dampers in the waste-gas flues.—H. B.

Coke and Gas; Apparatus for Making — J. Armstrong. Fr. Pat. 355,428, June 21, 1905. Under Int. Conv., June 22, 1904.

SEE Eng. Pat. 14,157 of 1904; this J., 1905, 665.—T. F. B.

Generator Consuming Small Coal or Coal Dust. Ver. Anthracit Werke G.m.b.H. First Addition, dated May 17, 1905, to Fr. Pat. 335,291, Sept. 11, 1903 (this J., 1904, 181).

THERE are described herein numerous improvements and modifications in the constructional details of the generator described in the principal patent, the objects being to facilitate the removal of clinker, ensure the equal distribution, and uniform descent, of the fuel, and to permit of the uninterrupted operation of the generator while the clinker is being removed.—H. B.

Hydrogen; Manufacture of — H. S. Elworthy. Fr. Pat. 355,324, June 17, 1905.

A MIXTURE of water-gas and steam is heated, in presence of such metals as nickel or iron, to a sufficiently high temperature to induce the reaction, $\text{CO} + \text{H}_2\text{O} = \text{CO}_2 + \text{H}_2$, whereby the hydrogen originally present in the water-gas is increased by a volume equal to that of the carbon monoxide contained in it. The proportion of carbon dioxide is also proportionately increased, but this may be readily removed by absorption by water under pressure, or by alkalis, or by other known means. Instead of completely converting the carbon monoxide contained in water-gas as described, the process may be arrested so that the conversion is only partial. The carbon dioxide formed is then withdrawn as before, and the mixture of carbon monoxide and hydrogen is passed over heated metallic nickel, as described in Eng. Pat. 14,333, of June 25, 1904 (this J., 1905, 1006), to obtain a gas rich in methane, thus, $\text{CO} + 3\text{H}_2 = \text{CH}_4 + \text{H}_2\text{O}$. The processes may be varied in described ways. (Reference is also made to Eng. Pat. 12,461 of May 31, 1903; and to Fr. Pat. 335,120, of May 30, 1903; this J., 1903, 900, and 1904, 112.)—E. S.

Methane or a Gaseous Mixture rich in Methane; Process of Preparing Pure — P. Sabatier. Fr. Pat. 355,325, June 17, 1905.

RICHE gas (this J., 1903, 411 and 1905, 78) or any analogous gas containing methane, hydrogen, carbon monoxide and carbon dioxide, is purified by passing it over copper turnings heated to about 600°C ., and is then led over nickel, cobalt, or iron (reduced from their oxides) heated to nearly 500°C . Under these conditions the carbon monoxide is converted partly into the dioxide and partly into methane, the resulting gas containing exclusively hydrogen, methane, and carbon dioxide. The last-named may be removed by washing with caustic alkali; or, if pure methane be required, the unwashed gases are mixed with so much hydrogen that, on passing the mixture over nickel, cobalt or iron, heated to 250° – 500°C ., the hydrogen and carbon dioxide react upon one another, with formation of methane and water. The water is removed by condensation, and the remaining gas consists of pure methane.—H. B.

Gases; Process of Carburetting Combustible — P. Sabatier. Fr. Pat. 355,419, June 20, 1905.

WATER-GAS, RICHÉ gas, Dowson gas and the like are first purified by passing them over copper, heated to about 600°C ., and then washing them in a scrubber; a quantity of purified acetylene is next added, and the mixture is passed over a catalyser consisting of iron, nickel, cobalt or copper (obtained by reduction of the oxides), heated to 100° – 200°C . The acetylene combines with a certain proportion of the hydrogen in the mixture, forming non-condensable, unsaturated hydrocarbons, which impart a high lighting power and calorific value to the gas produced.—H. B.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

(Continued from page 1103.)

Hydrocarbons in Louisiana Petroleum. II. C. E. Coates and A. Best. J. Amer. Chem. Soc., 1905, 27, 1317-1321 (see this J., 1903, 1312).

Two new crude petroleum and a sample of an oil-bearing sand have been examined. The preliminary examination of the specimens of petroleum gave the following results:

	Bayou Bonillon oil.	Bayou Laroupe oil.
Sp. gr. at 25° C.	0.9669	0.9604
Distillation begins (Engler flask) 275° C.	265° C.	265° C.
Fraction up to 300° C.; per cent.	11	8
Fraction 300°—350° C.; per cent.	62	7
Sulphuretted hydrogen evolved on heating	very little	none
Colour of lower fraction	yellow	yellow
Estimated depth of well	900 ft.	400 ft.
Percentage of sulphur in crude oil	0.57	low
Residue	asphaltic	asphaltic
Fuel value, B.T.U.	18500	—

The sample of oil-sand was extracted with gasoline,

and the solution evaporated, leaving 10 per cent. black oil being thus obtained. On distillation, the oil gave about 10 c.c. between 300° and 350° C., and about 10 c.c. between 350° and 380° C., the residue being asphaltic. On extraction with carbon bisulphide, the sand yielded 5.46 per cent. of oil, whilst by drying at 100° C. for four hours, "0.4 per cent. water" was lost. The fraction distilling between 300° and 350° C. had the refractive index 1.4833 at 25° C., whilst that distilling between 350° and 380° C. had the refractive index 1.5200. On combining the two fractions, a liquid having the sp. gr. 0.9047, and the refractive index 1.5013 at 25° C., was obtained, the figures for the corresponding fraction (300°—380° C.) of Bayou Bonillon petroleum being 0.9059 and 1.5080 respectively.

The fraction distilling between 300° and 360° C. from the Welsh oil (this J., 1903, 1342) showed a viscosity of 3.63 compared with water, at 29° C., in an Engler viscosimeter, and 2.1 as compared with water, at 38° C., in a standard Pennsylvania Railroad pipette.

A study was made of the fractions distilling up to 300° C. from Jennings, Welsh and Bayou Bonillon oils in a similar manner to that followed in the case of the Breaux Bridge oil (*loc. cit.*). The chief results obtained are shown in the following table:—

		Boiling point.	Specific gravity.	Refractive index at 25° C.	Most likely consisting of:	Remarks.
Jennings oil.	Fraction 1 ..	180—185° C. at 760 mm.	0.8873 at 22° C.	1.4535	C ₁₁ H ₂₀	Water-white, marked odour of turpentine, optically inactive.
	Fraction 2 ..	150°—155° C. at 80 mm.	0.8649 at 22° C.	1.4692	C ₁₃ H ₂₄	
	Fraction 3 ..	200°—205° C. at 80 mm.	0.8801 at 22° C.	1.4805	C ₁₆ H ₂₈	
Welsh oil.	Fraction 1 ..	145°—150° C. at 80 mm.	0.8551 at 22° C.	1.4662	C ₁₂ H ₂₂	
	Fraction 2 ..	165°—170° C. at 100 mm.	0.8679 at 25° C.	1.4666	C ₁₃ H ₂₄	
	Fraction 3 ..	175°—180° C. at 33 mm.	0.8736 at 28° C.	1.4760	C ₁₇ H ₂₂	
Bayou Bonillon oil.	Fraction 1 ..	140°—145° C. at 33 mm.	0.8557 at 25° C.	1.4691	C ₁₃ H ₂₄	
	Fraction 2 ..	170°—175° C. at 33 mm.	0.8871 at 29° C.	1.4828	C ₁₆ H ₂₈	
	Fraction 3 ..	190°—195° C. at 33 mm.	0.8966 at 27° C.	1.4883	C ₁₇ H ₃₀	
	Fraction 4 ..	200°—205° C. at 33 mm.	0.9006 at 27° C.	1.4916	C ₁₈ H ₃₂	
	Fraction 5 ..	225°—230° C. at 33 mm.	0.9104 at 28° C.	1.4972	C ₁₉ H ₃₄
